I State Variable description of digital filters	21
1 A review of the State Variable description of digital filters	23
1.1 The z-transform	23
1.2 Filter difference equation	24
1.3 Filter transfer function	25
1.4 Filter signal flow graph	25
1.5 State variable description of a signal flow graph	27
1.6 Controllability	29
1.7 Observability	30
1.8 Coordinate Transformations	30
1.9 State variable descriptions and the transfer function	30
1.9.1 Transformation of a transfer function to a state variable description	31
1.9.2 Transformation of a transfer function to a state variable description by continued fraction expansion	32
1.9.3 Transformation of a state variable description to a transfer function	34
1.9.4 Sensitivity of the state variable description of a transfer function	36
1.10 Time domain description	37
1.11 Unit Pulse Response	37
1.12 Factored state variable descriptions	37
1.12.1 Factored state variable filters with fractional delays	38
1.12.2 Construction of the factored state variable description	38
1.13 Block processing and decimation filters	41
2 Frequency transformations of state variable filters	45
2.1 Frequency Transformations	45
2.2 Frequency Transformation of the Transfer Function	46
2.3 Frequency Transformations of State Variable Filters	47
2.4 An example: frequency transformations of a 5-th order elliptic filter	49

3 Round-off noise in state variable filters	53
3.1 Quantisation noise in digital filters	53
3.2 Limit-cycle oscillations in digital filters	54
3.3 State variable filters and wide sense stationary inputs	54
3.3.1 The filter state covariance matrix	54
3.3.2 The output response to white noise in a state variable	55
3.3.3 Scaling State Variable Filters To Avoid Overflow	56
3.4 Estimation of output round-off noise in state variable filters	57
3.4.1 Rounding-to-minus-infinity quantisation noise	58
3.5 Minimization of round-off noise in the calculation of the state vector	59
3.6 Coefficient sensitivity	61
3.7 Factored state variable filters and wide sense stationary inputs	61
3.8 Frequency transformations and round-off noise	62
4 State variable filter realisation as a cascade of second order sections	63
4.1 Second Order State Variable Filters Optimised for Overflow and Round-Off Noise	63
4.2 Design equations for optimised second order state variable filters	63
4.3 Block optimal second order cascade filter realisations	66
4.4 An example of a second-order state-variable cascade filter	66
4.4.1 Comparison of calculated noise gains	66
4.4.2 Simulation results	67
4.4.3 Comparison with an N=10 example	69
4.5 Coefficient sensitivity and round-off noise of first-order and second-order all-pass filter sections	70
4.5.1 Searching for realisations of all-pass filter transfer functions	71
4.5.2 Maximum phase gradient and round-off noise of some first-order all-pass filter sections	71
4.5.3 Maximum phase gradient and round-off noise of some second-order all-pass filter sections	73
5 Filter synthesis by the Schur decomposition	93
5.1 The Schur algorithm	93
5.1.1 Computation of Schur polynomials	93
5.1.2 Orthonormality of Schur Polynomials	94
5.1.3 Polynomial Expansion Algorithm	96
5.1.4 Power calculation using the Schur algorithm	96
5.2 Derivation of Digital Lattice Filters	96

5.2.1	Derivation of FIR, All-Pole and All-Pass Lattice Filters	97
5.3	Derivation of the One-Multiplier IIR Lattice Filter	98
5.4	Derivation of the Normalised Lattice Filter	100
5.5	Derivation of the Scaled Normalised Lattice Filter	101
5.5.1	Example: synthesis of a 3rd order Butterworth lattice filter	103
5.6	State Variable Descriptions for Schur Lattice Filters	104
5.6.1	State variable description of the Schur FIR lattice filter	104
5.6.2	State variable description of the one-multiplier IIR lattice filter	105
5.6.3	State variable description of a retimed one-multiplier Schur lattice filter	106
5.6.4	State variable description of the scaled-normalised IIR lattice filter	108
5.7	Roundoff Noise Calculation in Schur Lattice Filters	110
5.7.1	Round-off noise of the normalised-scaled lattice filter	111
5.7.2	Round-off noise of the one multiplier lattice filter	119
5.7.3	Frequency transformations and Schur normalised-scaled lattice filter round-off noise	122
5.8	Examples of retiming Schur lattice filters	122
5.8.1	Retiming a 3-rd order lattice filter	122
5.8.2	Retiming a 4-th order Schur normalised-scaled lattice filter	123
5.8.3	Retiming a 6th-order Schur one-multiplier lattice filter	124
5.8.4	Frequency transformations of retimed Schur lattice filters	126
5.9	Summary	128
6	Orthogonal state variable filters	129
6.1	Definition of orthogonal state variable filters	129
6.2	The Lattice Orthogonal All-Pass Filter Section	130
6.3	Noise gain of orthogonal filters	130
6.4	Realisation of arbitrary filters from orthogonal sub-filters	131
6.4.1	An example of structural variations	133
7	Feedforward and feedback of state quantisation error in state variable filters	135
7.1	Problem formulation	135
7.2	Minimisation of round-off noise with $\delta = I$ and $\eta = 0$	137

8 IIR filter design using Sequential Quadratic Programming with the transfer function defined by pole and zero locations	141
8.1 Problem Statement	141
8.1.1 Solution of the constrained quasi-Newton optimisation problem	142
8.1.2 Choice of active constraints	143
8.1.3 Linearisation of peak constraints	144
8.1.4 Ensuring the stability of the IIR filter	145
8.1.5 Selecting an initial filter design	145
8.2 Examples of IIR filter design with SQP and constrained pole and zero locations	149
8.2.1 Introductory comments on the IIR filter design examples	149
8.2.2 Tarczynski et al. Example 2	152
8.2.3 Deczky's Example 3	155
8.2.4 Deczky's Example 1	163
8.2.5 Low-pass R=2 decimation filter	167
8.2.6 Band-pass R=2 decimation filter	173
8.2.7 Hilbert transform R=2 decimation filter	180
8.2.8 R=2 differentiator filter	183
8.2.9 Pink noise filter	187
8.2.10 Minimum phase R=2 filter	190
8.2.11 Minimum phase FIR bandpass filter	193
9 IIR filter design using Second Order Cone Programming	197
9.1 Second Order Cone Programming	197
9.2 Design of IIR filters with SOCP	197
9.3 Using the <i>SeDuMi</i> SOCP solver	199
9.4 An example of SOCP design of an IIR filter expressed in <i>gain-zero-pole</i> format with <i>SeDuMi</i>	200
9.5 Comparison of FIR and IIR low-pass filters having approximately flat pass-band group delay with symmetric FIR filters	208
9.6 SOCP MMSE design of a bandpass R=2 filter expressed in <i>gain-zero-pole</i> format with <i>SeDuMi</i>	210

10 IIR filter design with a pre-defined structure	213
10.1 Design of an IIR filter composed of second-order sections	213
10.1.1 Linear constraints on the stability of second-order filter sections	213
10.1.2 Linear constraints on limit-cycle oscillations in second-order filter sections	214
10.1.3 Design of an IIR filter composed of second order sections with <i>SeDuMi</i>	215
10.1.4 Some notes on the design of an IIR filter composed of second order sections with <i>SeDuMi</i>	220
10.2 Design of an IIR filter as the sum of two all-pass filters	221
10.2.1 Design of an IIR filter as the sum of two all-pass filters each composed of second-order sections	221
10.2.2 Design of an IIR filter as the sum of an all-pass filter composed of second-order sections and a delay	229
10.2.3 Design of an IIR filter as the sum of two all-pass filters each represented in pole-zero form	230
10.2.4 Design of an IIR filter as the sum of a delay and an all-pass filter represented in pole-zero form	247
10.2.5 Design of an IIR filter as the polyphase decomposition into two all-pass filters each represented in pole-zero form	254
10.3 Design of an IIR Schur lattice filter	260
10.3.1 Design of an IIR one-multiplier Schur lattice low-pass filter using SOCP	260
10.3.2 Design of an IIR one-multiplier Schur lattice low-pass filter using SQP	263
10.3.3 Design of an IIR one-multiplier Schur lattice band-pass filter using SQP	266
10.3.4 Design of an IIR one-multiplier Schur lattice Hilbert filter using SQP	271
10.3.5 Design of an IIR Schur normalised-scaled lattice low-pass filter using SQP	273
10.3.6 Design of an IIR low-pass filter with parallel Schur one-multiplier all-pass lattice filters using SOCP	276
10.3.7 Design of a parallel IIR Schur one-multiplier all-pass lattice band-pass filter using SOCP	279
10.3.8 Design of a parallel IIR Schur one-multiplier all-pass lattice band-pass Hilbert filter using SOCP	281
10.4 Design of IIR filters with a sharp transition band by frequency response masking	283
10.4.1 Review of Frequency Response Masking digital filters	283
10.4.2 Design of an FRM digital filter with an IIR model filter consisting of a cascade of second-order sections using SOCP	286
10.4.3 Design of an FRM digital filter with an IIR model filter represented in gain-pole-zero form using SOCP and PCLS optimisation	292
10.4.4 Design of an FRM digital filter with an allpass model filter represented in gain-pole-zero form using SOCP and PCLS optimisation	298
10.4.5 Design of an FRM digital filter with an IIR model filter consisting of parallel allpass filters	303
10.4.6 Design of an FRM low-pass digital filter with an all-pass Schur lattice model filter in parallel with a delay using SOCP and PCLS optimisation	309
10.4.7 Design of an FRM half-band digital filter with an allpass Schur lattice model filter using SOCP and PCLS optimisation	313
10.4.8 Design of an FRM Hilbert digital filter with an allpass Schur lattice model filter using SOCP and PCLS optimisation	319

III Design of IIR filters with integer coefficients

325

11 Signed-digit representation of filter coefficients	328
11.1 Lim's method for allocating signed-digits to filter coefficients	329
11.2 Ito's method for allocating signed-digits to filter coefficients	330
11.3 Signed-digit allocation of the coefficients of a Schur one-multiplier lattice filter	330
11.4 Signed-digit allocation of the coefficients of a symmetric FIR band-pass filter	338
12 Exhaustive search for integer and signed-digit filter coefficients	343
13 Searching for integer and signed-digit filter coefficients with the <i>bit-flipping</i> algorithm	344
13.1 Bit-flipping search for the signed-digit coefficients of a direct-form bandpass IIR filter	344
13.2 Bit-flipping search for the signed-digit coefficients of a normalised-scaled lattice bandpass IIR filter	347
13.3 Bit-flipping search for the signed-digit coefficients of a one-multiplier lattice bandpass IIR filter	348
13.4 Bit-flipping search for the signed-digit coefficients of a one-multiplier parallel-allpass lattice bandpass IIR filter	350
13.5 Bit-flipping search for the signed-digit coefficients of a minimum-phase bandpass FIR filter	353
13.6 Bit-flipping search for the signed-digit coefficients of a direct-form symmetric bandpass FIR filter	355
14 Branch-and-bound search for signed-digit coefficients	358
14.1 Branch-and-bound search for the 8-bit 3-signed-digit coefficients of a direct-form symmetric bandpass FIR filter	360
14.2 Branch-and-bound search for the 8-bit 3-signed-digit coefficients of a lattice band-pass IIR filter	362
14.3 Branch-and-bound search for the 10-bit 3-signed-digit coefficients of a lattice band-pass IIR filter	365
14.4 Branch-and-bound search for the 12-bit 3-signed-digit coefficients of a parallel all-pass lattice low-pass IIR filter	368
14.5 Branch-and-bound search for the 8-bit 3-signed-digit coefficients of a parallel all-pass lattice IIR elliptic low-pass filter	371
14.6 Branch-and-bound search for the 16-bit 4-signed-digit coefficients of a parallel all-pass lattice IIR elliptic low-pass filter	373
14.7 Branch-and-bound search for the 12-bit 3-signed-digit coefficients of a parallel all-pass lattice band-pass IIR filter	376
14.8 Branch-and-bound search for the 10-bit 3-signed-digit coefficients of a parallel all-pass lattice band-pass Hilbert IIR filter	379
14.9 Branch-and-bound search for the 12-bit 3-signed-digit coefficients of a parallel all-pass lattice band-pass Hilbert IIR filter	383
14.10 Branch-and-bound search for the coefficients of an FRM low-pass filter implemented with 12-bits and an average of 3-signed-digits	387
14.11 Branch-and-bound search for the coefficients of an FRM Hilbert filter implemented with 12-bits and 2-signed-digits	390
14.12 Branch-and-bound search for the 12-bit 2-signed-digit coefficients of an FIR Hilbert filter	394
14.13 Branch-and-bound search for the 12-bit 2-signed-digit coefficients of an FIR Hilbert band-pass filter	396

15 Successive coefficient relaxation search for signed-digit filter coefficients	398
15.1 SOCP-relaxation search for the signed-digit coefficients of a direct-form symmetric bandpass FIR filter	398
15.2 SQP-relaxation search for the signed-digit coefficients of a lattice bandpass IIR filter	400
15.3 SQP-relaxation search for the signed-digit coefficients of a lattice lowpass IIR filter	403
15.4 SOCP-relaxation search for the signed-digit coefficients of a parallel all-pass lattice low-pass IIR filter	406
15.5 SOCP-relaxation search for the signed-digit coefficients of a parallel all-pass lattice band-pass IIR filter	409
15.6 SOCP-relaxation search for the signed-digit coefficients of a lattice Hilbert IIR filter	412
15.7 SOCP relaxation search for the 12-bit 3-signed-digit coefficients of a FRM low-pass filter	414
15.8 SOCP-relaxation search for the signed-digit coefficients of an FRM Hilbert IIR filter with an all-pass lattice model filter	416
15.9 SOCP-relaxation search for the signed-digit coefficients of a direct-form FIR Hilbert filter	419
15.10 POP relaxation search for the signed-digit coefficients of a one-multiplier lattice bandpass filter	421
15.11 SOCP-relaxation search for the signed-digit coefficients of a lattice FIR filter	424
16 Semi-definite programming search for integer and signed-digit filter coefficients	429
16.1 SDP optimisation of the signed-digit coefficients of a direct-form symmetric FIR filter	430
16.2 SDP optimisation of the signed-digit coefficients of an FIR Hilbert filter	433
16.3 SDP optimisation of the signed-digit coefficients of an FIR Hilbert band-pass filter	435
16.4 SDP-relaxation search for the signed-digit coefficients of a lattice bandpass IIR filter	437
16.5 SDP-relaxation search for the signed-digit coefficients of a parallel allpass lattice elliptic low-pass IIR filter	440
16.6 SDP-relaxation search for the signed-digit coefficients of a parallel allpass lattice bandpass Hilbert IIR filter	443
17 Comparison of filter coefficient search methods for a 5th order elliptic filter with 6-bit integer and 2-signed-digit coefficients	447
17.1 Searching with the bit-flipping algorithm	447
17.2 Searching with the <i>Nelder-Mead</i> simplex algorithm	454
17.3 Searching with the <i>simulated annealing</i> algorithm	460
17.4 Searching with the <i>differential evolution</i> algorithm	467
17.5 Summary of the search algorithm comparison	473

IV Appendixes 475

A Review of Complex Variables	477
A.1 Complex Functions	477
A.2 Limit	477
A.3 The Cauchy-Riemann Equations	477
A.4 Line integrals in the complex plane	478
A.5 Cauchy's Integral Theorem	479
A.6 Cauchy's Integral Formula	479
A.7 Derivatives of an analytic function	480
A.8 Laurent's Theorem	480
A.9 Residues	480
A.10 Cauchy's Argument Principle	481
A.11 Rouché's Theorem	481
B Review of Legendre's elliptic integrals and Jacobi's elliptic functions	483
B.1 Doubly periodic functions	483
B.2 Legendre's elliptic integrals	483
B.3 Computation of Legendre's elliptic integrals	484
B.4 Jacobi's theta functions	486
B.5 Computation of Jacobi's theta functions	486
B.6 Jacobi's elliptic functions	487
B.7 Inverses of Jacobi's elliptic functions	488
B.8 Elementary identities for the elliptic integrals and elliptic functions	488
B.9 Related functions	489
B.10 Octave implementations	490
C Review of Lanczos tridiagonalisation of an unsymmetric matrix	492
D Review of Lagrange Interpolation	495
D.1 The barycentric Lagrange polynomial	495
D.2 Node distributions	496
E IIR filter amplitude, phase and group-delay frequency responses	499
F Gradient of the IIR filter amplitude response with respect to frequency	507

G Allpass filter frequency response	509
G.1 Allpass filter phase response	509
G.2 Allpass filter group delay response	510
H Gradients of the state variable filter frequency response	513
H.1 Gradients of the state variable filter complex frequency response	513
H.2 State variable filter squared-magnitude response	513
H.3 State variable filter phase response	514
H.4 State variable filter group-delay response	514
I Constrained non-linear optimisation	517
I.1 Newton's method for a quadratic function	517
I.2 Lagrange multipliers	517
I.3 The dual problem	518
I.4 Karush-Kuhn-Tucker conditions for constrained optimisation	518
I.5 Constrained optimisation using Newton's method	519
I.6 Local convergence	520
I.7 Quasi-Newton methods	520
I.7.1 Updating the Hessian approximation with the <i>Broyden-Fletcher-Goldfarb-Shanno</i> (BFGS) formula	521
I.7.2 A modified Cholesky factorisation of the Hessian	521
I.7.3 Wright's modification for degenerate constraints	523
I.7.4 Bertsekas' modification to the Hessian	524
I.8 Penalty and barrier methods	525
I.8.1 Penalty functions	525
I.8.2 Barrier functions	527
I.9 Finding the step size	527
I.9.1 Line search with the Golden-Section	527
I.9.2 Inexact step-size selection	528
I.9.3 Lanczos step-size selection	530
I.10 Initial solution with the Goldfarb-Idnani algorithm	530
I.11 Implementation examples	535

J Fourier transform of the Gaussian function	539
J.1 Preliminary results	539
J.1.1 Integral of the Gaussian function	539
J.1.2 Fourier transform of the derivative of a function	539
J.2 Derivation of the Fourier transform of the Gaussian function in the frequency domain	540
K Design of IIR digital filter transfer functions	541
K.1 Design of Butterworth IIR filters	541
K.1.1 Continuous Time Second Order Butterworth Filter Prototypes	541
K.1.2 Design of discrete time filters with the bilinear transform	542
K.1.3 Design of second order Butterworth digital filters with the bilinear transform	542
K.2 Low passband sensitivity IIR filters	544
K.2.1 Structural Boundedness	544
K.2.2 Filter realisation as the sum of all-pass functions	545
K.2.3 A note on the numerical calculation of the spectral factor	547
K.2.4 Examples of parallel all-pass filter synthesis	547
K.3 Design of Elliptic IIR filters with a reduced number of multipliers	552
K.3.1 Elliptic filter design with the <i>Landen transformation</i>	552
K.3.2 Design of elliptic filters with minimal-Q	553
K.4 Saramäki's method for the design of IIR filters with zeros on the unit circle	558
K.4.1 Optimisation of a low-pass filter with denominator order higher	559
K.4.2 Optimisation of a low-pass filter with denominator order lower	561
K.4.3 Surma-aho and Saramäki method of unconstrained optimisation of an initial IIR filter	564
K.5 Johansson and Saramäki design of all-pass complementary IIR filters	570
L Design of FIR digital filter transfer functions	577
L.1 Low passband sensitivity FIR lattice filters	577
L.1.1 Lattice decomposition of an FIR digital filter	577
L.1.2 Finite-wordlength properties of the lattice FIR filter	578
L.1.3 State variable description of the complementary FIR lattice filter	579
L.1.4 Design of the complementary FIR digital filter	580
L.2 Constrained least-squared error optimisation of FIR digital filters	583
L.2.1 Examples of the design of constrained least-squared error symmetric FIR filters	585
L.3 Constrained least-squared error optimisation of direct-form FIR Hilbert digital filters	588

L.3.1	Design of a constrained least-squared error anti-symmetric FIR Hilbert filter	590
L.3.2	Design of a constrained least-squared error anti-symmetric FIR Hilbert band-pass filter	590
L.4	Constrained mini-max error optimisation of FIR digital filters	593
L.4.1	Alternation theorem	593
L.4.2	<i>Hofstetter's</i> algorithm for mini-max FIR filter approximation	594
L.4.3	<i>Parks-McClellan</i> algorithm for mini-max FIR filter approximation	601
L.5	Design of FIR filters with flat pass-bands and equi-ripple stop-bands	609
L.5.1	Design of FIR low-pass filters with flat pass-bands and equi-ripple stop-bands	609
L.5.2	Design of FIR band-pass filters with flat pass-bands and equi-ripple stop-bands	611
L.5.3	Design of FIR low-pass differentiators with equi-ripple stop-bands	615
L.6	Design of half-band FIR filters	616
L.6.1	Vaidyanathan's "TRICK" for the design of FIR half-band filters	616
L.6.2	Design of equi-ripple FIR half-band filters	617
L.7	Design of equi-ripple FIR filters with Zolotarev polynomials	626
L.7.1	The Zolotarev polynomials	626
L.7.2	Narrow-band FIR filter design with the Zolotarev polynomials	634
L.7.3	Almost equi-ripple low-pass FIR filter design with the Zolotarev polynomials	645

List of Algorithms

1.1	Procedure for reordering the nodes of a primitive signal flow graph	26
1.2	Derivation of the state variable description of a signal flow graph	27
1.3	Transformation of a transfer function to a state variable description	31
1.4	Continued fraction expansion of a rational transfer function	32
1.5	Transformation of state variable description to direct form	34
1.6	Leverrier's algorithm for finding the resolvent of the state transition matrix, A [129, Algorithm 8A.12]	35
1.7	<i>La Budde's</i> algorithm for finding the characteristic polynomial of A [133, Algorithm 2]	36
3.1	Recursive calculation of the covariance matrix	55
3.2	Minimisation of the noise gain	59
3.3	Optimisation of the noise gain	60
4.1	Construction of optimised second order state variable filters[129, Figure 9.14.1].	64
4.2	Bomar second order optimised state variable filter sections [18, Equation 17]. (See also [129, Figure 9.12.1])	65
4.3	Bomar Type III second order optimised state variable filter sections [18, Equation 23]	65
5.1	Schur polynomial expansion (see <i>Parhi</i> [73, Section 12.2.3])	96
5.2	One-multiplier lattice sign assignment	99
5.3	Construction of a state variable description of the Schur FIR lattice filter	104
5.4	Construction of a state variable description of the Schur one-multiplier lattice filter	105
5.5	Construction of a state variable description of the retimed Schur one-multiplier lattice filter	107
5.6	Construction of a state variable description of the Scaled-Normalised Lattice	109
7.1	Minimisation of round off noise in error feedback/feedforward state variable filters. (See <i>Williamson</i> [30, Theorem 5.2]).	137
8.1	Exchange algorithm for multiband FIR filters. (<i>Selesnick, Lang and Burrus</i> . See [59, p.498]).	144
8.2	Compute the powers of a matrix (see <i>Golub and van Loan</i> , Algorithm 11.2.2)	147
11.1	Conversion of 2's complement numbers to the canonical signed-digit representation (<i>Parhi</i> [73, Section 13.6.1]).	329
11.2	Modified signed-digit allocation heuristic of <i>Ito et al.</i> [136]	330
B.1	Carlson's algorithm for computing the R_F function [14, Algorithm 1]	485
B.2	Carlson's algorithm for computing the R_C function [14, Algorithm 2]	485
B.3	Carlson's algorithm for computing the R_J function [14, Algorithm 3]	485
B.4	Carlson's algorithm for computing the R_D function [14, Algorithm 4]	486
C.1	<i>Lanczos</i> tridiagonalisation of an unsymmetric matrix	493
I.1	The sequential quadratic programming method	520
I.2	Cholesky factorisation of an $n \times n$ positive-definite symmetric matrix, W	522
I.3	Line search using the Armijo rule	529
I.4	Line search using Wolfe conditions	529
I.5	Line search using the Goldstein conditions	529
I.6	The <i>Goldfarb-Idnani</i> dual algorithm [25]	531
K.1	Filter realisation as the sum of all-pass functions	547
K.2	<i>Surma-aho</i> and <i>Saramäki</i> method for finding an initial IIR filter in <i>gain-pole-zero</i> form [71, pp. 958-959]	564
L.1	Construction of a state variable description of the complementary FIR lattice filter	579

Introduction

An IIR filter can approximate a desired amplitude response with fewer coefficients than an FIR filter^a. The design of IIR filters is more difficult than the design of FIR filters. FIR filters are inherently stable. An FIR filter design problem can be formulated as a convex optimisation problem with a global solution (see, for example, Wu *et al.* [144]). The coefficient-response surface of an IIR filter rational polynomial transfer function is more complicated than that of an FIR polynomial transfer function. An IIR filter design procedure must find a locally optimal solution that satisfies the specifications and the coefficients of the IIR transfer function must be constrained to ensure that the IIR filter is stable. This report describes my experiments in the design of IIR digital filters with constraints on the amplitude, phase and group delay responses. I intended to show that it is possible to design an “acceptable” or “good-enough” IIR digital filter with coefficients that use a limited number of shift-and-add operations and so do not require software or hardware multiplications.

My experiments are programmed in the *Octave* language [68]. Octave is an “almost” compatible open-source-software clone of the commercial *MATLAB* package [158]. The minimum-mean-squared-error (MMSE) approximation to the required response is found by either a sequential-quadratic-programming (SQP) solver or by the *SeDuMi* second-order-cone-programming (SOCP) solver originally written by *Sturm* [148]. The stability of the filter is ensured by constraining the pole locations of the filter transfer function when expressed in gain-pole-zero form [3, 85] or by constraining the reflection coefficients of a tapped all-pass lattice filter implementation [4, 73]. A valid initial solution for the MMSE solver is found by “eye” or by using the WISE method of *Tarczynski et al.* [9]. A peak-constrained-least-squares (PCLS) solution is found by the exchange algorithm of *Selesnick et al.* [59]. The lattice filter implementation with integer coefficients has good round-off noise and coefficient sensitivity performance. For coefficient word lengths greater than 10-bits the coefficients are allocated signed-digits by the algorithm of *Lim et al.* [173] or that of *Ito et al.* [136] and branch-and-bound or relaxation search is used to find an acceptable response. For lesser coefficient word-lengths simulated-annealing of the signed-digit rounded coefficients gives the best results.

The state variable description of digital filters Part I is a review of the *state variable* description of digital filters. The state variable description models the internal structure and round-off noise performance of the digital filter. Chapter 5 shows the state variable description of the tapped all-pass lattice filter. This part summarises chapters 8 to 10 of the book “*Digital Signal Processing*” by *Roberts and Mullis* [129] and chapter 12 of “*VLSI Digital Signal Processing Systems : Design and Implementation*” by *Parhi* [73].

Optimising the IIR filter frequency response Part II reviews constrained optimisation of the IIR filter transfer function.

One formulation of the filter optimisation problem is to minimise the *weighted squared error* of the frequency response:

$$\begin{aligned} \text{minimise } & \mathcal{E}_H(x) = \int W(\omega) |H(x, \omega) - H_d(\omega)|^2 d\omega \\ \text{subject to } & H \text{ is stable} \end{aligned} \tag{1}$$

where x is the coefficient vector of the filter, \mathcal{E}_H is the weighted sum of the squared error, $W(\omega)$ is the frequency weighting, $H(x, \omega)$ is the filter frequency response and $H_d(\omega)$ is the desired filter frequency response. The solution proceeds by choosing an initial coefficient vector and calling the SQP solver to find the coefficient vector that optimises a second-order approximation to \mathcal{E}_H . The solution is repeated until the difference between successive errors or successive coefficient vectors is sufficiently small.

Alternatively, the optimisation problem can be expressed as a *weighted mini-max* problem:

$$\begin{aligned} \text{minimise } & \max W(\omega) |H(x, \omega) - H_d(\omega)| \\ \text{subject to } & H \text{ is stable} \end{aligned} \tag{2}$$

^aSection 9.5 compares the frequency responses of FIR and IIR implementations of a low-pass filter with approximately flat pass-band group delay.

Similarly, in this case, given an initial coefficient vector, the solution proceeds by calling the SOCP solver to find the coefficient vector that minimises the maximum error of a first-order approximation to H .

Constraints on the IIR filter response are applied by the *Peak-Constrained-Least-Squares* (PCLS) exchange algorithm of *Selesnick, Lang and Burrus* [59]. Appendix L.2 describes the use of the PCLS method of *Selesnick et al.* to design symmetric FIR filters with constraints on the filter amplitude response.

Chapter 8 applies the *Sequential Quadratic Programming* (SQP) method to the optimisation of the frequency of an IIR filter. The SQP method is reviewed in Appendix I. That review makes extensive use of the books by *Nocedal and Wright* [69], *Ruszczynski* [8] and *Bertsekas* [26]. I chose to write my own SQP solver in Octave. In chapter 8, I follow *Deczky* [3] and *Richards* [85] and optimise the filter response with respect to the gain and pole and zero locations of the filter rather than the coefficients of the transfer function polynomial. When the transfer function is expressed in *gain-pole-zero* form the stability of the filter is ensured by constraining the radius of the poles of the filter. Calculation of the response and gradient from the coefficients of the transfer function polynomials is simpler but the stability constraint on the transfer function denominator is more complex and may exclude valid alternative designs. Appendix E, derives expressions for the amplitude, phase and delay responses and gradients of an IIR filter in terms of the gain-pole-zero coefficients. The SQP method requires that at each step the optimisation problem is initialised with the second-order derivatives (ie: the Hessian matrix) of the response with respect to the coefficients.

Chapter 9 is based on the description of IIR filter design using *Second-Order-Cone-Programming* (SOCP) by *Lu and Hinamoto* [160]. SOCP is a subclass of *convex programming* [139]. See the review articles by *Alizadeh and Goldfarb* [35] and *Lobo et al.* [94] for a description of applications of SOCP. Unlike SQP, SOCP optimisation does not require the the Hessian of the response. In this report I use the public domain *SeDuMi* SOCP solver originally written by *Jos Sturm* [149].

Chapter 10 considers optimisation of the filter transfer function of several filter structures. The simplest IIR filter structure is the “*direct form*” implementation of the filter transfer function. This filter structure rarely has good round-off noise and coefficient sensitivity when the coefficients are truncated. *Regalia et al.* [109] and *Vaidyanathan et al.* [116] show that an IIR digital filter composed of two all-pass filters connected in parallel has desirable coefficient sensitivity and round-off noise performance. *Renfors and Saramäki* [92, 93], describe IIR digital filterbanks as a “*polyphase*” combination of all-pass digital filters. *Gray and Markel* [4] and *Parhi* [73, Chapter 12] describe the synthesis of digital filters as tapped lattice structures. The lattice filter is stable if the lattice coefficients, k_l , have $|k_l| < 1$. *Johansson and Wanhammar* [50], *Milić and Ćertić* [78] and *Lu and Hinamoto* [160] describe efficient, sharp transition-band IIR filter designs using the *frequency masking* approach described for FIR filters by *Lim* [171].

Truncating the IIR filter coefficients Part III considers algorithms for optimising the frequency response of the IIR filter with truncated or quantised rather than exact or floating point coefficients. The truncated coefficients are represented as *N-bit 2's complement* or *M-signed-digit* numbers. The signed-digit representation reduces the complexity and power requirements of the filter. *Lim et al.* [173] and *Ito et al.* [136] describe methods of allocating the number of signed-digits used by each coefficient. This part considers methods of searching the space of truncated coefficients for the best filter response. A brute force, exhaustive, search is likely to take too much time. Part III considers methods of searching for the best filter response with truncated filter coefficients. Figure 1 shows the response of a 20'th order tapped Schur lattice bandpass filter with denominator coefficients only in z^{-2} and 31 non-zero coefficients. The figure compares the filter responses for the exact coefficients and 10-bit signed-digit coefficients with an average of 3 signed-digits allocated to each coefficient by the method of *Ito et al.* [136]. After successive SQP-relaxation optimisations of the signed-digit coefficient values, 64 signed-digits and 33 shift-and-add operations are required to implement the coefficient multiplications.

Chapter 17, shows the results of searching for the truncated coefficients of a 5th order elliptic filter having various structures and 6-bit coefficients with the *bitflipping* algorithm of *Krukowski and Kale* [6], and the *simplex, differential evolution* and *simulated annealing* routines from the Octave-Forge *optim* package [102].

Reproducing my results The Octave scripts referred to in this report generate long sequences of floating point operations. I recommend reading “*What Every Computer Scientist Should Know About Floating-point Arithmetic*” by *Goldberg* [44] and “*The perfidious polynomial*” by *Wilkinson* [61]. In the latter, Wilkinson reminisces about programming polynomial root finding on early computers. He comments that “*explicit polynomial equations with ill-conditioned roots are remarkably common*” but that if “*one already knows the roots, then the polynomial can be evaluated without any loss of accuracy*.” As an example, Figure 2 shows the results of calling the Octave *roots* function to find the roots of the binomial polynomial of order 20 with the expression *roots (bincoeff (20, 0 : 20))*. In fact, by definition, the roots are all -1 . Figure 3 repeats the example with the oct-file *qzsolve*, an implementation using 128-bit floating-point numbers based on the function *gsl_poly_complex_solve* from the GNU GSL library[125]^b.

^bThe *MPSolve* multi-precision polynomial solver [24] finds the expected roots. The package includes an Octave interface.

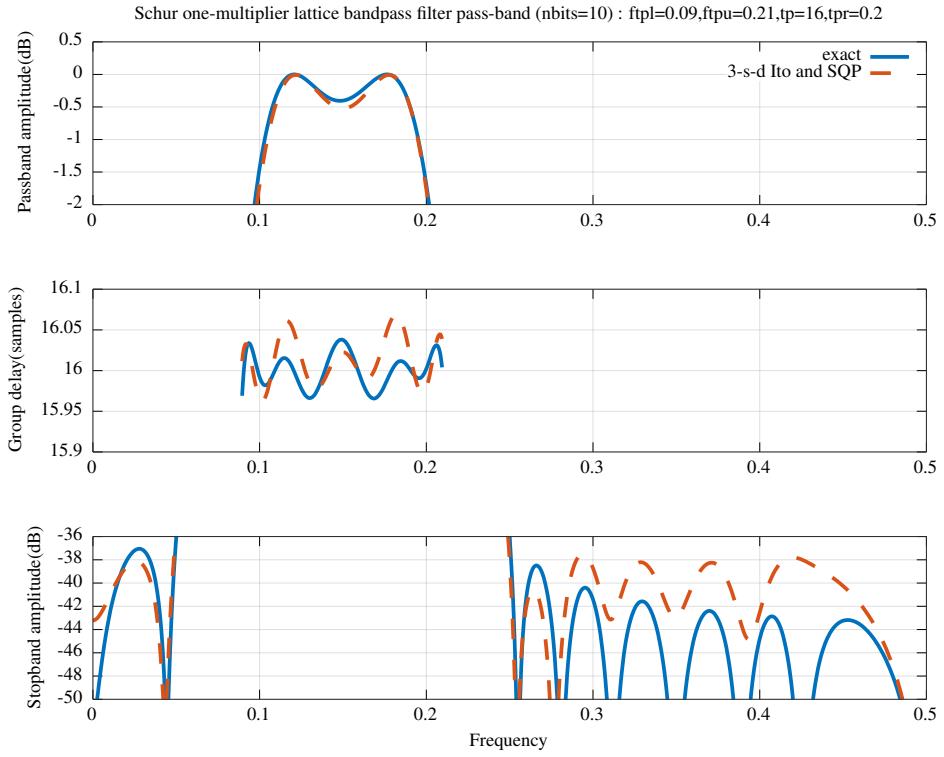

Figure 1: Comparison of the pass-band and stop-band amplitude responses and group delay responses for a Schur one-multiplier lattice bandpass filter with exact coefficients and with 10 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SQP-relaxation optimisation.

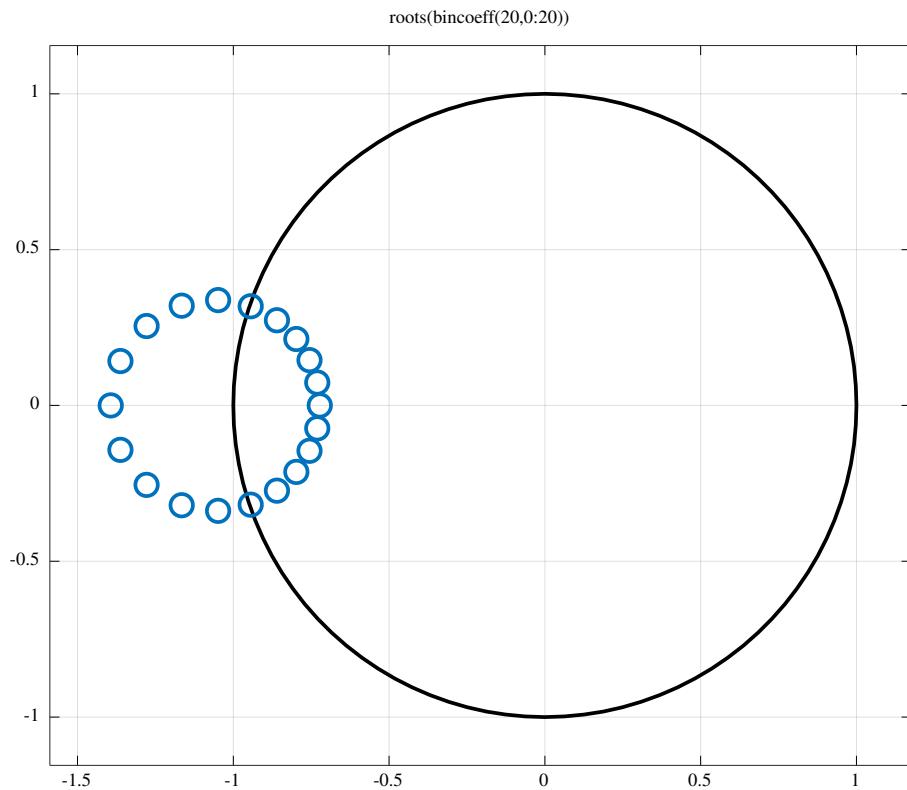

Figure 2: Plot of the roots of the binomial polynomial of order 20 calculated by the Octave *roots* function

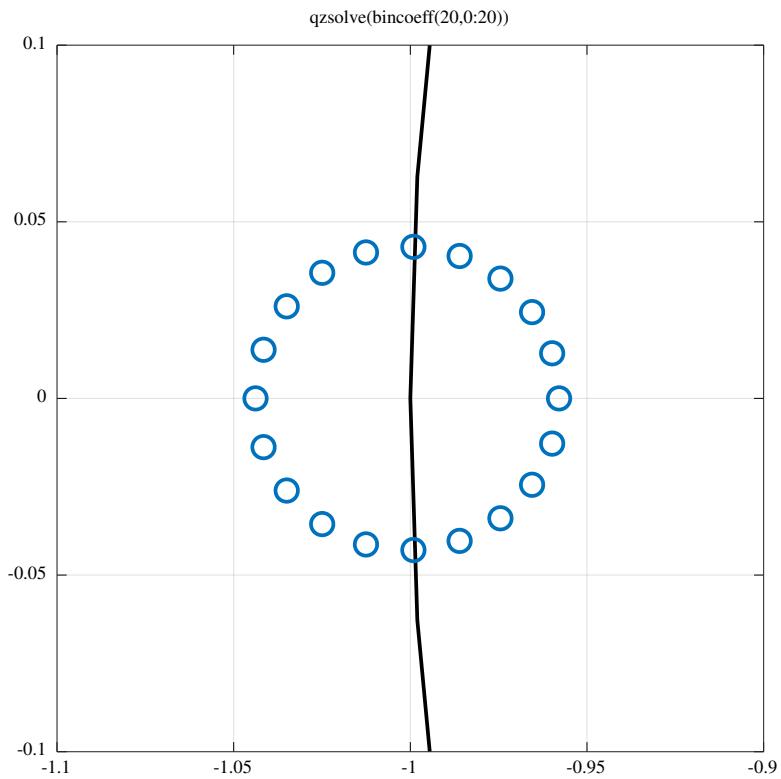

Figure 3: Plot of the roots of the binomial polynomial of order 20 calculated by the *qzsolve* oct-file function using 128-bit floating point numbers

THE RESULTS SHOWN IN THIS REPORT WERE OBTAINED ON MY SYSTEM RUNNING WITH A PARTICULAR COMBINATION OF CPU ARCHITECTURE, OPERATING SYSTEM, LIBRARY VERSIONS, COMPILER VERSION AND OCTAVE VERSION. YOUR SYSTEM WILL ALMOST CERTAINLY BE DIFFERENT. YOU MAY NEED TO MODIFY A SCRIPT TO RUN ON YOUR SYSTEM.

Part I

State Variable description of digital filters

Chapter 1

A review of the State Variable description of digital filters

This chapter briefly summarises parts of the text *Digital Signal Processing* by *Roberts and Mullis* [129]. Appendix A reviews the necessary complex variables theory.

1.1 The z-transform

The bi-lateral *z-transform* of a sequence f is

$$F(z) = Z\{f\} = \sum_{k=-\infty}^{\infty} f(k) z^{-k}$$

where z is a complex variable. The region of convergence (ROC) of the series is that part of the z -plane for which

$$\sum_k |f(k) z^{-k}| < \infty$$

If f is causal then the z-transform is one-sided:

$$F(z) = \sum_{k=0}^{\infty} f(k) z^{-k}$$

The *Cauchy integral theorem*, shown in Appendix A.5, can be used to invert the z-transform. Start by selecting a circular contour, C , centred at the origin and lying in the ROC. Multiply each side of the z-transform by z^{n-1} and integrate along C :

$$\oint_C z^{n-1} F(z) dz = \sum_{k=-\infty}^{\infty} \oint_C f(k) z^{n-1-k} dz$$

Cauchy's *integral lemma* states

$$\oint_C z^n dz = \begin{cases} 2\pi i & n = -1 \\ 0 & n \neq -1, \text{ integral} \end{cases}$$

so the terms in the sum vanish except for $k = n$ and

$$f(n) = \frac{1}{2\pi i} \oint_C z^{n-1} F(z) dz$$

For rational z-transforms the contour integrals are usually evaluated by finding the residues of the integrand. See Appendix A.

The inversion integral can be used to derive Parseval's theorem for the z-transform of two sequences. Following *Roberts and Mullis* [129, Section 3.4], let f and g be causal sequences with z-transforms $F(z)$ and $G(z)$, respectively. Define the z-transform of the product as

$$Z\{f \cdot g\} = \sum_{k=0}^{\infty} f(k) g(k) z^{-k}$$

Substituting the inversion integral for \mathbf{f}

$$\begin{aligned} Z\{\mathbf{f} \cdot \mathbf{g}\} &= \frac{1}{2\pi i} \sum_{k=0}^{\infty} \oint_C g(k) s^{k-1} F(s) z^{-k} ds \\ &= \frac{1}{2\pi i} \oint_C s^{-1} F(s) \sum_{k=0}^{\infty} g(k) [zs^{-1}]^{-k} ds \\ &= \frac{1}{2\pi i} \oint_C s^{-1} F(s) G\left(\frac{z}{s}\right) ds \end{aligned}$$

If $|z| = 1$ lies in the ROC of the integrand then

$$Z\{\mathbf{f} \cdot \mathbf{g}\} = \frac{1}{2\pi i} \oint_C s^{-1} F(s) G\left(\frac{1}{s}\right) ds$$

If $\mathbf{f} = \mathbf{g}$ then we have the discrete form of Parseval's theorem:

$$\begin{aligned} Z\{\mathbf{f} \cdot \mathbf{f}\} &= \sum_{k=0}^{\infty} f^2(k) z^{-k} \\ &= \frac{1}{2\pi i} \oint_C z^{-1} F(z) F(z^{-1}) dz \end{aligned}$$

If C is the contour $|z| = 1$ then, after expanding terms in $e^{i\theta}$:

$$\sum_{k=0}^{\infty} f^2(k) = \frac{1}{2\pi} \int_{-\pi}^{\pi} |F(e^{i\theta})|^2 d\theta$$

1.2 Filter difference equation

The standard difference equation (SDE) of a digital filter is

$$\sum_{l=0}^n a_l y(k-l) = \sum_{l=0}^m b_l u(k-l), \quad a_0 = 1 \text{ and } k \geq 0 \quad (1.1)$$

or

$$\mathbf{a} * \mathbf{y} = \mathbf{b} * \mathbf{u}$$

$u(k)$ and $y(k)$ are the input and output sequences, respectively. If \mathbf{y}^0 is a solution of the homogenous equation (HE), $\mathbf{y} * \mathbf{a} = 0$, then

$$\mathbf{a} * (\mathbf{y} + \mathbf{y}^0) = \mathbf{b} * \mathbf{u}$$

The polynomial $a(z)$ is known as the *characteristic* polynomial of the HE. The n roots $\lambda_1, \dots, \lambda_n$ of \mathbf{a} define the solutions of the HE since

$$\sum_{l=0}^n a_l z^{k-l} = z^k a(z)$$

and if λ is a root of $a(z)$ then

$$\sum_{l=0}^n a_l \lambda^{k-l} = \lambda^k a(\lambda) = 0 \quad (1.2)$$

If the roots are distinct then there are n solutions of the form $y_l(k) = \lambda_l^k$, $1 \leq l \leq n$ and solutions of the HE are of the form

$$y^0(k) = \sum_{l=1}^n c_l \lambda_l^{k-l}$$

The case of repeated roots can be treated by differentiating Equation 1.2. Roots of multiplicity m generate m solutions $y_l(k) = k^{l-1} \lambda^{k-l+1}$, $1 \leq l \leq m$.

Every solution of the HE is a linear combination of these solutions

$$y^0(k) = \sum_{l=1}^n c_l y_l(k)$$

The constants c_l are usually chosen so that the filter is stable and causal.

The unit-pulse response sequence of the filter, \mathbf{h} , is found by setting the input $\mathbf{u} = \delta$

$$\sum_{l=0}^n a_l h(k-l) = \sum_{l=0}^n b_l \delta(k-l), \quad a_0 = 1 \text{ and } k \geq 0 \quad (1.3)$$

Further, if \mathbf{h} is causal, then it is of the form

$$h(k) = \begin{cases} 0, & k < 0 \\ b_0, & k = 0 \\ \sum_{l=1}^n c_l y_l(k), & k > 0 \end{cases}$$

The initial conditions $h(1), \dots, h(n)$ that determine the c_l are obtained by direct evaluation of Equation 1.3.

Finally, if the filter is Bounded-Input-Bounded-Output (BIBO) stable then

$$\sum_{l=-\infty}^{\infty} |h(k)| < \infty$$

For the case of distinct roots, \mathbf{h} has the form

$$h(k) = \sum_{l=1}^n c_l \lambda_l^k, \quad k > 0$$

If the unit-pulse response is causal, then BIBO stability requires that $|\lambda_l| < 1, l = 1, \dots, n$.

1.3 Filter transfer function

The filter transfer function is related to the z-transform of the filter difference equation, Equation 1.1, by

$$H(z) = \frac{b(z)}{a(z)} = \frac{\sum_{l=0}^m b_l z^{-l}}{\sum_{l=0}^n a_l z^{-l}}$$

The transfer function, $H(z)$, can also be written

$$H(z) = g \frac{\prod_{l=1}^n (z - z_l)}{\prod_{l=1}^m (z - p_l)}$$

The p_l are the roots of $a(z)$ and are called the poles of $H(z)$. The z_l are the roots of $b(z)$ and are called the zeros of $H(z)$. $g = H(0)$ is a gain factor.

1.4 Filter signal flow graph

Signal flow graphs are *primitive* if

1. All branch gains are either constant or z^{-1} (a unit delay)
2. There are no delay free loops in the graph
3. There are a finite number of nodes and branches

Algorithm 1.1 Procedure for reordering the nodes of a primitive signal flow graph

1. Examine each unit delay. If there is an incoming branch at the output then isolate the output of the unit delay by inserting a unit gain branch as shown in Figure 1.1
 2. Label all input nodes and all unit delay output nodes with 0
 3. All nodes that can be calculated from nodes labelled 0 are labelled 1
 4. If any nodes are unlabelled increment the label and repeat until all nodes are labelled
-

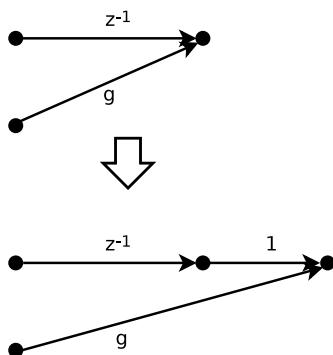

Figure 1.1: Isolating a unit delay from an incoming branch

Figure 1.2: Second order direct form filter

Algorithm 1.2 Derivation of the state variable description of a signal flow graph

1. Replace each unit delay with the equivalent path shown in Figure 1.4
 2. Remove the unit delays thereby creating new outputs x'_i and inputs x_i . Note that $x'_i(k) \triangleq x_i(k+1)$
 3. Eliminate all nodes that are not inputs or outputs
 4. Replace the unit delays
-

The implementation of primitive signal flow graphs requires *node reordering*, shown in Algorithm 1.1. For example Figure 1.2 shows the signal flow graph of a second order *direct form* filter. The nodes are labelled according to Algorithm 1.1. The labelled nodes are:

- $S_0: u, v_2, v_3$
- $S_1: v_1 = u - a_1v_2 - a_2v_3$
- $S_2: y = b_0v_1 + b_1v_2 + b_2v_3$

With updates

- $v_2 \leftarrow v_1$
- $v_3 \leftarrow v_2$

Then in the z -domain

$$\begin{aligned} y(z) &= b_0z^2 + b_1z^1 + b_2 \\ u(z) &= z^2 + a_1z + a_0 \end{aligned}$$

so the transfer function is

$$H(z) = \frac{b_0z^2 + b_1z + b_2}{z^2 + a_1z + a_0}$$

n' th order direct form filters can be generated recursively by:

$$\begin{aligned} A_k(z) &= z^{-1}[a_k + A_{k+1}(z)] \\ B_k(z) &= z^{-1}[b_k + B_{k+1}(z)] \end{aligned}$$

where $A_{n+1}(z) = B_{n+1}(z) = 0$. The filter structure recursion is initialised with:

$$\begin{aligned} y(z) &= b_0v + B_1(z)v \\ u(z) &= v + a_0A_1(z)v \end{aligned}$$

so that

$$H(z) = \frac{b_0 + B_1(z)}{1 + a_0A_1(z)}$$

See Figure 1.3.

1.5 State variable description of a signal flow graph

The state variable description of a signal flow graph is derived by Algorithm 1.2.

Figure 1.2 shows the signal flow graph for a second order direct form filter.

(a) Left hand side termination

(b) k^{th} internal section

Figure 1.3: Recursive generation of direct form filters

Figure 1.4: Unit delay equivalent

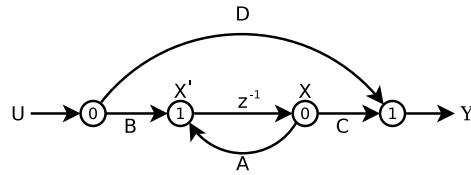

Figure 1.5: Signal flow graph of a state variable filter

The time domain state variable equations for this filter are:

$$\begin{bmatrix} x(k+1) \\ y(k) \end{bmatrix} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} x(k) \\ u(k) \end{bmatrix} \quad (1.4)$$

where:

$$\begin{aligned} A &= \begin{bmatrix} 0 & 1 \\ -a_2 & -a_1 \end{bmatrix} \\ B &= \begin{bmatrix} 0 \\ 1 \end{bmatrix} \\ C &= [b_2 - a_2 b_0, \quad b_1 - a_1 b_0] \\ D &= b_0 \end{aligned}$$

The z -domain state variable equations for this filter are:

$$\begin{bmatrix} zX \\ Y \end{bmatrix} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} X \\ U \end{bmatrix} \quad (1.5)$$

Figure 1.5 shows the signal flow graph for the state variable filter of Equation 1.5. The matrix A is called the *state transition matrix*.

If the arrows in Figure 1.5 are reversed and the inputs to each node become the outputs then the state-variable description of the *transposed* signal flow graph is:

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix}^T = \begin{bmatrix} A^T & C^T \\ B^T & D \end{bmatrix}^T \quad (1.6)$$

1.6 Controllability

The matrix pair (A, B) is said to be *controllable* if and only if $\det [B \ AB \ \dots \ A^{n-1}B] \neq 0$.

The n-by-n matrix $[B \ AB \ \dots \ A^{n-1}B]$ is called the *controllability matrix*.

If the matrix pair (A, B) is controllable then the system

$$\begin{aligned} x(0) &= 0 \\ x(k+1) &= Ax(k) + Bu(k) \end{aligned}$$

can be driven to any specified vector $x(n)$.

PROOF: From above

$$\begin{aligned} x(n) &= \sum_{l=1}^n A^{l-1}Bu(n-l) \\ &= [B \ AB \ \dots \ A^{n-1}B] \begin{bmatrix} u(n-1) \\ u(n-2) \\ \vdots \\ u(0) \end{bmatrix} \end{aligned}$$

The input $u(k)$, $0 \leq k < n$, producing $x(n)$ can be found by inverting the controllability matrix.

1.7 Observability

The matrix pair (A, C) is said to be *observable* if the matrix $\begin{bmatrix} C & CA & \cdots & CA^{n-1} \end{bmatrix}$ is invertible (for a single output variable).

If the matrix pair (A, C) is observable then the state $x(0)$ can be uniquely determined from $(u(k), y(k))$ for $0 \leq k < n$.

PROOF : From the matrix equations for $x(k)$ and $y(k)$

$$\begin{bmatrix} y(0) \\ y(1) \\ \vdots \\ y(n-1) \end{bmatrix} = \begin{bmatrix} C \\ CA \\ \vdots \\ CA^{n-1} \end{bmatrix} x(0) + \begin{bmatrix} D & 0 & \cdots & 0 \\ CB & D & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ CA^{n-2}B & CA^{n-3}B & \cdots & D \end{bmatrix} \begin{bmatrix} u(0) \\ u(1) \\ \vdots \\ u(n-1) \end{bmatrix}$$

The right-hand term reduces to an n -by-1 column vector. $x(0)$ is found by inverting the observability matrix.

1.8 Coordinate Transformations

Let T be an n -by- n non-singular matrix and $q(k) = T^{-1}x(k)$ then the state variable equations have the same form except that $\{A, B, C, D\} \leftarrow \{T^{-1}AT, T^{-1}B, CT, D\}$. In matrix form:

$$\begin{bmatrix} A' & B' \\ C' & D' \end{bmatrix} = \begin{bmatrix} T^{-1}AT & T^{-1}B \\ CT & D \end{bmatrix} = \begin{bmatrix} T & 0 \\ 0 & 1 \end{bmatrix}^{-1} \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} T & 0 \\ 0 & 1 \end{bmatrix}$$

1.9 State variable descriptions and the transfer function

From the z -domain state variable matrix shown in Equation 1.5

$$X(z) = (zI - A)^{-1} BU$$

so

$$Y(z) = C(zI - A)^{-1} BU + DU$$

and the transfer function is

$$H(z) = D + C(zI - A)^{-1} B \quad (1.7)$$

The transfer function of the *transpose* of the signal flow diagram shown in 1.5 is the same as that of the original diagram.

The similarity transformation, $\{A, B, C, D\} \leftarrow \{T^{-1}AT, T^{-1}B, CT, D\}$, leaves the transfer function, $H(z)$, unchanged^a:

$$H(z) = D + C(zI - A)^{-1} B \quad (1.8)$$

$$= D + CTT^{-1}(zI - A)^{-1}(T^{-1})^{-1}T^{-1}B \quad (1.9)$$

$$= D + CT[T^{-1}(zI - A)T]^{-1}T^{-1}B \quad (1.10)$$

$$= D + CT(zI - T^{-1}AT)^{-1}T^{-1}B \quad (1.11)$$

The poles of $H(z)$ are the eigenvalues of A . The zeros of $H(z)$ are related to the $n+1$ components in C and D via a system of linear equations. This system of equations is invertible if the controllability matrix $\begin{bmatrix} B & AB & \cdots & A^{n-1}B \end{bmatrix}$ is non-singular. The term $(zI - A)^{-1}$ is called the *matrix resolvent*. The determinant $p(z) = \det(zI - A)$ is called the *characteristic polynomial* of A .

The transfer function can be written

$$H(z) = \frac{b_0 z^n + b_1 z^{n-1} + \cdots + b_{n-1} z + b_n}{z^n + a_1 z^{n-1} + \cdots + a_{n-1} z + a_n} \quad (1.12)$$

^aRecall that $(AB)^{-1} = B^{-1}A^{-1}$

The denominator of $H(z)$ is the characteristic polynomial of A . The unit impulse response is related to the coefficients of the numerator and denominator polynomials of $H(z)$ by

$$\begin{bmatrix} 1 & 0 & \cdots & 0 \\ a_1 & 1 & \cdots & \vdots \\ \vdots & \vdots & \ddots & 0 \\ a_n & a_{n-1} & \cdots & 1 \end{bmatrix} \begin{bmatrix} h_0 \\ h_1 \\ \vdots \\ h_n \end{bmatrix} = \begin{bmatrix} b_0 \\ b_1 \\ \vdots \\ b_n \end{bmatrix}$$

1.9.1 Transformation of a transfer function to a state variable description

Algorithm 1.3 converts a rational transfer function to the equivalent direct form state variable description^b. An *Octave* implementation is shown in the file *tf2Abcd.m*.

Algorithm 1.3 Transformation of a transfer function to a state variable description

Given a transfer function

$$\begin{aligned} H(z) &= \frac{\hat{b}(z)}{\hat{a}(z)} \\ &= \frac{b_0 z^n + b_1 z^{n-1} + \cdots + b_n}{z^n + a_1 z^{n-1} + \cdots + a_n} \end{aligned}$$

the direct form state variable description is

$$H(z) = D + C(zI - A)^{-1}B$$

where

$$\begin{aligned} A &= \begin{bmatrix} 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \\ -a_n & -a_{n-1} & \cdots & -a_1 \end{bmatrix} \\ B &= [0 \ 0 \ \cdots \ 0 \ 1]^T \\ C &= [b_n - b_0 a_n \ \cdots \ b_1 - b_0 a_1] \\ D &= b_0 \end{aligned}$$

PROOF of Algorithm 1.3: Firstly, show the identity

$$(zI - A)\Psi(z) = \hat{a}(z)B$$

with $\Psi(z) = [1 \ z \ \cdots \ z^{n-1}]^T$ uniquely defines the matrix:

$$A = \begin{bmatrix} \alpha_{1,1} & \alpha_{1,2} & \cdots & \alpha_{1,n} \\ \alpha_{2,1} & \alpha_{22} & \cdots & \alpha_{2,n} \\ \vdots & \vdots & \ddots & \vdots \\ \alpha_{n,1} & \alpha_{n,2} & \cdots & \alpha_{n,n} \end{bmatrix}$$

and the column vector: $B = [\beta_1 \ \cdots \ \beta_n]^T$. For row i :

$$z^i - \beta_i \left(z^n + \sum_{j=1}^n a_j z^{n-j} \right) = \sum_{j=1}^n \alpha_{i,j} z^{j-1}$$

If $i \neq n$, then, equating coefficients, $\beta_i = 0$, so $\alpha_{i,i+1} = 1$ and $\alpha_{i,j} = 0$ if $i \neq j + 1$. If $i = n$ then $\beta_i = 1$ and

$$-\sum_{j=1}^n a_j z^{n-j} = \sum_{j=1}^n \alpha_{n,j} z^{j-1}$$

^bAppendix 1.9.2 shows the continued fraction expansion of a rational transfer function into state variable form.

Algorithm 1.4 Continued fraction expansion of a rational transfer function

Given a rational transfer function $H(z) = \frac{\hat{b}(z)}{\hat{a}(z)} = \frac{\sum_{j=0}^N b_j z^{N-j}}{z^N + \sum_{j=1}^N a_j z^{N-j}}$ find the continued fraction expansion:

```

 $\hat{a}_1(z) = \hat{a}(z)$ 
 $\hat{b}_1(z) = \hat{b}(z) - b_0 \hat{a}_1(z)$ 
for  $k = 1, \dots, N$  do
    Find  $q_k(z)$  and  $\hat{b}_{k+1}(z)$  so that  $\hat{a}_k(z) = q_k(z) \hat{b}_k(z) - \hat{b}_{k+1}(z)$ 
     $\hat{a}_{k+1}(z) = \hat{b}_k(z)$ 
end for

```

so

$$\begin{aligned}\alpha_{n,1} &= -a_n \\ &\vdots \\ \alpha_{n,n} &= -a_1\end{aligned}$$

Now find vector $C = [c_1 \ c_2 \ \dots \ c_n]$ and scalar $D = \delta$ that satisfy

$$D\hat{a}(z) + C\Psi = \hat{b}(z)$$

Expanding

$$\delta \left(z^n + \sum_{j=1}^n a_j z^{n-j} \right) + \sum_{j=1}^n c_j z^{j-1} = \sum_{j=0}^n b_j z^{n-j}$$

Equating coefficients

$$\begin{aligned}\delta &= b_0 \\ c_j &= b_{n-j+1} - b_0 a_{n-j+1} \quad 1 \leq j \leq n\end{aligned}$$

1.9.2 Transformation of a transfer function to a state variable description by continued fraction expansion

See *Roberts and Mullis* [129, Problems 8.16, 10.13 to 10.16] and *Mitra and Sherwood* [143]. Algorithm 1.4 calculates the continued fraction expansion of a rational transfer function.

The continued fraction expansion of a state variable filter is shown in Figure 1.6. Figure 1.6a shows the signal flow graph for a first order approximation to a state variable filter. The state variable equations for Figure 1.6a are:

$$\begin{aligned}zX_1 &= \alpha_0 X_1 + bU + G_1 X_1 \\ Y &= cX_1 + dU\end{aligned}$$

The corresponding transfer function, $G(z)$, is:

$$G(z) = d + \frac{bc}{z - \alpha_0 - G_1(z)}$$

Figure 1.6b shows the addition of a second section for $G_1(z)$ with:

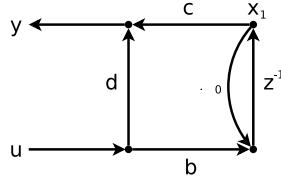

$$\begin{aligned}zX_2 &= \alpha_1 X_2 + \gamma_1 X_1 + bU + G_2 X_2 \\ Y_1 &= \beta_1 X_2 \\ G_1(z) &= \frac{\beta_1 \gamma_1}{z - \alpha_1 - G_2(z)}\end{aligned}$$

Finally, in Figure 1.6c, for a filter of order N :

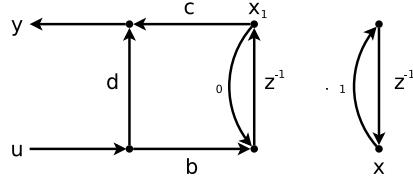

$$G_{N-1}(z) = \frac{\beta_{N-1} \gamma_{N-1}}{z - \alpha_{N-1}}$$

The state variable equations for Figure 1.6c are:

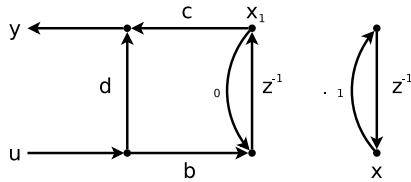

$$x_1(k+1) = \alpha_0 x_1 + \beta_1 x_2 + bu$$

(a) Signal flow graph of a first order approximation to a state variable filter

(b) Signal flow graph of a second order approximation to a state variable filter

(c) Signal flow graph of a continued fraction expansion of a state variable filter

Figure 1.6: Continued fraction expansion of a state variable filter

$$x_2(k+1) = \gamma_1 x_1 + \alpha_1 x_2 + \beta_2 x_3$$

⋮

$$x_{N-1}(k+1) = \gamma_{N-2} x_{N-2} + \alpha_{N-2} x_{N-1} + \beta_{N-1} x_N$$

$$x_N(k+1) = \gamma_{N-1} x_{N-1} + \alpha_{N-1} x_N$$

$$y(k) = cx_1 + du$$

or:

$$\left[\begin{array}{cc} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{array} \right] = \left[\begin{array}{ccccccc|c} \alpha_0 & \beta_1 & 0 & 0 & 0 & \cdots & 0 & b \\ \gamma_1 & \alpha_1 & \beta_2 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \gamma_2 & \alpha_2 & \beta_3 & 0 & \cdots & 0 & 0 \\ 0 & 0 & \gamma_3 & \alpha_3 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & \gamma_{N-2} & \alpha_{N-2} & \beta_{N-1} & 0 \\ 0 & 0 & \cdots & 0 & 0 & \gamma_{N-1} & \alpha_{N-1} & 0 \\ \hline c & 0 & \cdots & 0 & 0 & 0 & 0 & d \end{array} \right]$$

The tridiagonal state transition matrix means that the state variable description is “pipelined”. The continued fraction expansion apparently has N additional parameters compared to the direct form but, by construction, the ratios $\frac{\alpha_i}{\gamma_i}$ and $\frac{\beta_i}{\gamma_i}$ are fixed. Furthermore, only a diagonal similarity transform maintains the tridiagonal filter structure so only state rescaling is possible. *Golub and Van Loan* [38, Section 9.4.3] describe *unsymmetric Lanczos tridiagonalisation* of an arbitrary matrix, summarised in Appendix C. The Octave function *lanczos_tridiag* implements Lanczos tridiagonalisation.

The Octave function *contfrac* implements Algorithm 1.4 and returns the equivalent state variable description. The Octave script *contfrac_test.m* implements the continued fraction expansion of a 5th order elliptic low-pass filter with cutoff frequency $0.05f_S$. The noise gains of the continued fraction filter and the corresponding minimum noise and direct-form state variable filter implementations are 127, 0.928 and $583e3$ respectively^c.

^cSee Chapter 3.

1.9.3 Transformation of a state variable description to a transfer function

This section describes three methods for finding the transfer function of a state variable description.

Using the controllability matrix

Algorithm 1.5 uses the controllability matrix to find the characteristic polynomial of the state transition matrix, A . The transfer function follows from Equation 1.7.

Algorithm 1.5 Transformation of state variable description to direct form

If

1. the matrix pair (A, B) is controllable so that $\det [B \ AB \ A^2B \ \dots \ A^{n-1}B] \neq 0$.
2. the characteristic function of the state transition matrix, A , is $\det(zI - A) = a_0z^n + a_1z^{n-1} + \dots + a_n$ with $a_0 = 1$.
3. the state vectors are: $\begin{cases} x(0) = 0 \\ x(k+1) = Ax(k) + Ba_k \end{cases}$

then

1. $x(n+1) = 0$
2. If $T = [x(n) \ x(n-1) \ \dots \ x(1)]$ then

$$T^{-1}AT = \begin{bmatrix} 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \\ -a_n & -a_{n-1} & \cdots & -a_1 \end{bmatrix}$$

$$T^{-1}B = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}$$

PROOF of Algorithm 1.5: By repeated application, the state vectors, x , at time $k+1$ are:

$$x(k+1) = \sum_{i=0}^k A^{k-i}Ba_i$$

and

$$x(n+1) = \left(\sum_{i=0}^n A^{n-i}a_i \right) B$$

The Cayley-Hamilton theorem states that a matrix is a solution of its own characteristic polynomial so the expression in the parentheses is zero. Factorising

$$\begin{aligned} T &= [x(n) \ x(n-1) \ \dots \ x(1)] \\ &= [A^{n-1}B \ A^{n-2}B \ \dots \ B] \begin{bmatrix} 1 & 0 & \cdots & 0 \\ a_1 & 1 & \ddots & \vdots \\ \vdots & \vdots & \ddots & 0 \\ a_{n-1} & a_{n-2} & \cdots & 1 \end{bmatrix} \end{aligned}$$

If the matrix pair (A, B) is controllable then T is invertible. Now consider the state variables $q(k)$ of the direct form filter with the transfer function denominator polynomial $z^n + a_1z^{n-1} + \dots + a_n$ and make the input to the filter be the coefficients of this denominator polynomial (recall that by definition $q(k) = T^{-1}x(k)$):

$$q(0) = 0$$

$$\begin{aligned}
q(1) &= \begin{bmatrix} 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \\ -a_n & -a_{n-1} & \cdots & -a_1 \end{bmatrix} \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix} \\
q(2) &= \begin{bmatrix} 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \\ -a_n & -a_{n-1} & \cdots & -a_1 \end{bmatrix} \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix} + \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix} a_1 = \begin{bmatrix} 0 \\ \vdots \\ 1 \\ 0 \end{bmatrix} \\
&\vdots \\
q(n) &= \begin{bmatrix} 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \\ -a_n & -a_{n-1} & \cdots & -a_1 \end{bmatrix} \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix} + \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix} a_n = \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \\
q(n+1) &= 0
\end{aligned}$$

Form the matrix with columns consisting of the states $\{q(n+1), \dots, q(2)\}$:

$$\begin{aligned}
\begin{bmatrix} q(n+1) & q(n) & \cdots & q(2) \end{bmatrix} &= \begin{bmatrix} 0 & 1 & \cdots & 0 \\ \vdots & \cdots & \ddots & \vdots \\ 0 & \cdots & 0 & 1 \\ 0 & \cdots & 0 & 0 \end{bmatrix} \\
&= T^{-1}AT \begin{bmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & \vdots \\ \vdots & \vdots & \ddots & 0 \\ 0 & \cdots & 0 & 1 \end{bmatrix} + \begin{bmatrix} 0 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ a_n & a_{n-1} & \cdots & a_1 \end{bmatrix}
\end{aligned}$$

The result follows.

LeVerrier's algorithm

In practice, I have found that the simplest method of finding $(zI - A)^{-1}$ (sometimes referred to as the matrix *resolvent*) is by matrix inversion. An alternative, slower, but more accurate method for finding the resolvent of a matrix is LeVerrier's algorithm [129, Algorithm 8A.12] shown in Algorithm 1.6. Note that Leverrier's algorithm calculates the characteristic polynomial

Algorithm 1.6 Leverrier's algorithm for finding the resolvent of the state transition matrix, A [129, Algorithm 8A.12]

To find $p(z) = \sum_{k=0}^n z^{n-k} a_k$ and $(zI - A)^{-1} = \frac{1}{p(z)} \sum_{k=0}^{n-1} z^{n-1-k} \bar{A}_k$ perform the following recursion:

```

 $a_0 = 1, \bar{A}_0 = I$ 
for  $k = 1, \dots, n$  do
   $a_k = -\frac{1}{k} \text{trace}(A\bar{A}_{k-1})$ 
   $\bar{A}_k = A\bar{A}_{k-1} + a_k I$ 
end for

```

of A as a by-product. In this case the characteristic polynomial of the state-transition matrix is the denominator polynomial of the transfer function, which is known. The recursion in \bar{A}_k is justified by rearranging the expansion of the resolvent shown in Algorithm 1.6 and then equating coefficients of z :

$$\begin{aligned}
\sum_{k=0}^n z^{n-k} a_k I &= (zI - A) \sum_{k=0}^{n-1} z^{n-1-k} \bar{A}_k \\
&= z^n \bar{A}_0 + \sum_{k=1}^{n-1} z^{n-k} (\bar{A}_k - A\bar{A}_{k-1}) - A\bar{A}_{n-1}
\end{aligned}$$

La Budde's algorithm for finding the characteristic polynomial of an upper Hessenberg matrix

Wilkinson [62, Section 57, Chapter 6], Rehman [138, Chapter 6], and Rehman and Ipsen [133] describe La Budde's algorithm for the calculation of the characteristic polynomial of an *upper Hessenberg* matrix, reproduced here as Algorithm 1.7 [133],

Algorithm 1.7 *La Budde's algorithm for finding the characteristic polynomial of A* [133, Algorithm 2]

Given: $H = \begin{bmatrix} \alpha_1 & h_{1,2} & \cdots & \cdots & h_{1,n} \\ \beta_2 & \alpha_2 & h_{2,3} & & \vdots \\ \ddots & \ddots & \ddots & & \vdots \\ & \ddots & \ddots & & h_{n-1,n} \\ 0 & & \beta_n & \alpha_n \end{bmatrix}$, the $n \times n$ upper Hessenberg reduction of A , find $a_1 \dots a_n$:

$$\begin{aligned} a_1^{(1)} &= -\alpha_1 \\ a_1^{(2)} &= a_1^{(1)} - \alpha_2 \\ a_2^{(2)} &= \alpha_1 \alpha_2 - h_{1,2} \beta_2 \\ \textbf{for } k = 3, \dots, n \textbf{ do} \\ a_1^{(k)} &= a_1^{(k-1)} - \alpha_k \\ \textbf{for } l = 2, \dots, k-1 \textbf{ do} \\ a_l^{(k)} &= a_l^{(k-1)} - \alpha_k a_{l-1}^{(k-1)} - \sum_{m=1}^{l-2} h_{k-m,k} \beta_k \cdots \beta_{k-m+1} a_{l-m-1}^{(k-m-1)} - h_{k-l+1,k} \beta_k \cdots \beta_{k-l+2} \\ \textbf{end for} \\ a_k^{(k)} &= -\alpha_k a_{k-1}^{(k-1)} - \sum_{m=1}^{k-2} h_{k-m,k} \beta_k \cdots \beta_{k-m+1} a_{k-m-1}^{(k-m-1)} - h_{1,k} \beta_k \cdots \beta_2 \\ \textbf{end for} \\ a_k &= a_k^{(n)}, \quad 1 \leq k \leq n \end{aligned}$$

Algorithm 2]. Rehman [138, Appendix B] provides a MATLAB implementation, *labudde.m*^d. Rehman shows that the numerical performance of *La Budde's* method compares favourably with the eigenvalue method, $p(z) = \prod_{k=1}^n (z - \lambda_k)$, where the λ_k are the (possibly repeated) eigenvalues of A . When the characteristic polynomial is known, the resolvent can be calculated with the matrix recursion of *LeVerrier's* algorithm.

The first stage of *La Budde's* method reduces the non-symmetric matrix, A , to *upper Hessenberg* form, H (see Golub and van Loan [38, Section 7.4]). The determinant of a matrix is unchanged by replacing a row of the matrix by linear combinations with other rows, so H and A have the same characteristic polynomial. Rehman and Ipsen [133, pp.10-11] justify *La Budde's* algorithm as follows (lightly edited for consistency with my notation):

La Budde's method computes the characteristic polynomial of an upper Hessenberg matrix, H , by successively computing the characteristic polynomials of leading principal submatrices H_k of order k . Denote the characteristic polynomial of H_k by $p_k(z) = \det(zI - H_k)$, $1 \leq k \leq n$, where $p(z) = p_n(z)$. The recursion for computing $p(z)$ is [62, Section 6.57.1]

$$\begin{aligned} p_0(z) &= 1 \\ p_1(z) &= z - \alpha_1 \\ p_k(z) &= (z - \alpha_1)p_{k-1}(z) - \sum_{m=1}^{k-1} h_{k-m,k} \beta_k \cdots \beta_{k-m+1} p_{k-m-1}(z) \end{aligned} \tag{1.13}$$

where $2 \leq k \leq n$. The recursion for $p_k(z) = \sum_{m=0}^k z^{k-m} a_m^{(k)}$ is obtained by developing the determinant of $zI - H_k$ along the last row of H_k . Each term in the sum contains an element in the last column of H_k and a product of subdiagonal elements. Equating like powers of z in Equation 1.13 gives recursions for individual coefficients a_k .

1.9.4 Sensitivity of the state variable description of a transfer function

Thiele [81] analyses the sensitivity of the frequency response of linear state space digital filters with respect to the coefficients. Differentiation of the resolvent, $R = (zI - A)^{-1}$, is simplified by the matrix identity:

$$\begin{aligned} RR^{-1} &= I \\ \frac{dR}{d\rho} R^{-1} + R \frac{dR^{-1}}{d\rho} &= 0 \\ \frac{dR^{-1}}{d\rho} &= -R^{-1} \frac{dR}{d\rho} R^{-1} \end{aligned}$$

^dI have edited *labudde.m* to make it compatible with Octave

where ρ represents the components of the matrix R . With this identity, the gradients of $H(z)$ are found by differentiating Equation 1.7:

$$\begin{aligned}\frac{\partial H(z)}{\partial z} &= -C(zI - A)^{-2}B \\ \frac{\partial H(z)}{\partial \alpha} &= C(zI - A)^{-1}\frac{\partial A}{\partial \alpha}(zI - A)^{-1}B \\ \frac{\partial H(z)}{\partial \beta} &= C(zI - A)^{-1} \\ \frac{\partial H(z)}{\partial \gamma} &= (zI - A)^{-1}B \\ \frac{\partial H(z)}{\partial \delta} &= I\end{aligned}$$

where α, β, γ and δ represent the components of A, B, C and D respectively.

1.10 Time domain description

If the input sequence is zero then in the time-domain, given $x(k_0)$

$$x(k+1) = Ax(k), k > k_0$$

The matrix powers of A tend to 0 as k approaches infinity if and only if the eigenvalues λ_k of A satisfy

$$|\lambda_k| < 1, k = 1, \dots, n$$

This is equivalent to the stability condition that the poles of $H(z)$ lie inside the unit circle in the z -plane since the eigenvalues of A are the roots of the polynomial $\hat{a}(z) = \det(zI - A)$ which is the denominator polynomial of the transfer function $H(z)$. If the matrix A is stable then

$$x(k) = \sum_{l=1}^{\infty} A^{l-1}Bu(k-l)$$

1.11 Unit Pulse Response

The input and output sequences are related by the convolution, $y = h * u$. The state variable form is:

$$\begin{aligned}y(k) &= Cx(k) + Du(k) \\ &= \sum_{l=1}^{\infty} CA^{l-1}Bu(k-l) + Du(k) \\ &= \sum_{l=-\infty}^{\infty} h(l)u(k-l)\end{aligned}$$

For these to agree

$$h(k) = \begin{cases} 0 & k < 0 \\ D & k = 0 \\ CA^{k-1}B & k > 0 \end{cases}$$

1.12 Factored state variable descriptions

See *Roberts and Mullis* [129, Section 8.4]. Equation 1.4 assumes that the left-hand side is calculated concurrently. If that is not the case, then the *factored* state variable description is more appropriate. This models individual computations that are done

(a) Signal flow graph of a factored state variable filter

(b) Signal flow graph of a retimed factored state variable filter

Figure 1.7: Factored state variable filters (See [129, Figure 8.4.6].)

separately but in a fixed cyclic order. The number of factors is the number of delay free paths in the PSFG description. For L factors:

$$\begin{aligned} q_0(k) &= \begin{bmatrix} x(k) \\ u(k) \end{bmatrix} \\ q_i(k) &= F_i q_{i-1}(k), 1 \leq i \leq L \\ \begin{bmatrix} x(k+1) \\ y(k) \end{bmatrix} &= q_L(k) \end{aligned}$$

The corresponding state variable description is

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} = F_L F_{L-1} \dots F_1$$

1.12.1 Factored state variable filters with fractional delays

Figure 1.7a shows the signal flow graph of a factored state variable filter with L factors. The longest delay free path has length L . The factors F_1 and F_L are:

$$\begin{aligned} F_1 &= \begin{bmatrix} F_{11} & F_{12} \end{bmatrix} \\ F_L &= \begin{bmatrix} F_{L1} \\ F_{L2} \end{bmatrix} \end{aligned}$$

Figure 1.7b shows the result of retiming the filter with a delay of $z^{-1/L}$ after each factor. The loop gain and therefore the transfer function $H(z)$ are unchanged. The longest delay free path is now 1.

The factored and retimed filter has a reduced delay free path at the expense of a higher sub-sampling clock rate.

1.12.2 Construction of the factored state variable description

To construct a FSVD from a PSFG, first find the sets $\{S_0, S_1, \dots, S_L\}$ of node variables and let v_k be a vector representing the nodes in S_k . In particular:

$$v_0 = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \\ u \end{bmatrix}$$

Figure 1.8: Signal flow graph of two cascaded state variable filters

where the x_k are the outputs of the unit delays. Each variable in S_k is a linear combination of the variables in

$$\{S_0 \cup S_1 \cup \dots \cup S_{k-1}\}$$

so there is a coefficient matrix G_k for which:

$$v_k = G_k \begin{bmatrix} v_{k-1} \\ v_{k-2} \\ \vdots \\ v_0 \end{bmatrix} \quad 1 \leq k \leq L$$

Finally let G_0 be a matrix that picks out the next-state and outputs:

$$\begin{bmatrix} x'_1 \\ x'_2 \\ \vdots \\ x'_n \\ y \end{bmatrix} = G_0 \begin{bmatrix} v_L \\ v_{L-1} \\ \vdots \\ v_0 \end{bmatrix}$$

and the FSVD is:

$$\begin{bmatrix} x' \\ y \end{bmatrix} = G_0 \begin{bmatrix} G_L \\ I \end{bmatrix} \begin{bmatrix} G_{L-1} \\ I \end{bmatrix} \cdots \begin{bmatrix} G_1 \\ I \end{bmatrix} \begin{bmatrix} x \\ u \end{bmatrix}$$

Factoring cascaded state variable filters

As an example, Figure 1.8 shows two state variable filters connected in cascade.

The node variable sets are:

$$S_0 = \{x_1, x_2, u\}$$

$$S_1 = \{w, x'_1\}$$

$$S_2 = \{y, x'_2\}$$

where:

$$\begin{bmatrix} w \\ x'_1 \\ x_1 \\ x_2 \\ u \end{bmatrix} = \begin{bmatrix} C_1 & 0 & D_1 \\ A_1 & 0 & B_1 \\ I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ u \end{bmatrix}$$

$$\begin{bmatrix} y \\ x'_2 \\ w \\ x'_1 \\ x_1 \\ x_2 \\ u \end{bmatrix} = \begin{bmatrix} D_2 & 0 & 0 & C_2 & 0 \\ B_2 & 0 & 0 & A_2 & 0 \\ I & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 & I \end{bmatrix} \begin{bmatrix} w \\ x'_1 \\ x_1 \\ x_2 \\ u \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ x'_2 \\ y \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & I & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 & 0 & 0 \\ I & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} y \\ x'_2 \\ w \\ x'_1 \\ x_1 \\ x_2 \\ u \end{bmatrix}$$

The factored state variable equations are:

$$\begin{aligned} \begin{bmatrix} x'_1 \\ x'_2 \\ y \end{bmatrix} &= \begin{bmatrix} 0 & I & 0 \\ B_2 & 0 & A_2 \\ D_2 & 0 & C_2 \end{bmatrix} \begin{bmatrix} C_1 & 0 & D_1 \\ A_1 & 0 & B_1 \\ 0 & I & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ u \end{bmatrix} \\ &= \begin{bmatrix} A_1 & 0 & B_1 \\ B_2 C_1 & A_2 & B_2 D_1 \\ D_2 C_1 & C_2 & D_2 D_1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ u \end{bmatrix} \end{aligned}$$

Factoring a feedback connection of state variable filters

Roberts and Mullis [129, Problem 8.9] show a feedback connection of two MIMO state-variable systems:

$$\begin{aligned} x'_1 &= A_1 x_1 + [B_1 \quad B_2] \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} \\ \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} &= \begin{bmatrix} C_1 \\ C_2 \end{bmatrix} x_1 + \begin{bmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} \end{aligned}$$

and

$$\begin{aligned} x'_2 &= A_2 x_2 + [b_1 \quad b_2] \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} \\ \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} x_2 + \begin{bmatrix} d_{11} & d_{12} \\ d_{21} & d_{22} \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} \end{aligned}$$

The feedback connections are $u_2 = v_1$ and $w_1 = y_2$. A delay-free loop is avoided by setting $D_{22} = 0$ or $d_{11} = 0$. Choosing the latter, the state equations are, after substitution:

$$\begin{aligned} x'_1 &= A_1 x_1 + B_1 u_1 + B_2 v_1 \\ y_1 &= C_1 x_1 + D_{11} u_1 + D_{12} v_1 \\ y_2 &= C_2 x_1 + D_{21} u_1 + D_{22} v_1 \\ x'_2 &= A_2 x_2 + b_1 y_2 + b_2 w_2 \\ v_1 &= c_1 x_2 + d_{12} w_2 \\ v_2 &= c_2 x_2 + d_{21} y_2 + d_{22} w_2 \end{aligned}$$

The node variable sets are:

$$\begin{aligned} S_0 &= \{x_1, x_2, u_1, w_2\} \\ S_1 &= \{v_1\} \\ S_2 &= \{x'_1, y_1, y_2\} \\ S_3 &= \{x'_2, v_2\} \end{aligned}$$

where:

$$\begin{bmatrix} v_1 \\ x_1 \\ x_2 \\ u_1 \\ w_2 \end{bmatrix} = \begin{bmatrix} 0 & c_1 & 0 & d_{12} \\ I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ u_1 \\ w_2 \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ y_1 \\ y_2 \\ v_1 \\ x_1 \\ x_2 \\ u_1 \\ w_2 \end{bmatrix} = \begin{bmatrix} B_2 & A_1 & 0 & B_1 & 0 \\ D_{12} & C_1 & 0 & D_{11} & 0 \\ D_{22} & C_2 & 0 & D_{21} & 0 \\ I & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 & I \end{bmatrix} \begin{bmatrix} v_1 \\ x_1 \\ x_2 \\ u_1 \\ w_2 \end{bmatrix}$$

$$\begin{bmatrix} x'_2 \\ v_2 \\ x'_1 \\ y_1 \\ y_2 \\ v_1 \\ x_1 \\ x_2 \\ x_2 \\ u_1 \\ w_2 \end{bmatrix} = \begin{bmatrix} 0 & 0 & b_1 & 0 & 0 & A_2 & 0 & b_2 \\ 0 & 0 & d_{21} & 0 & 0 & c_2 & 0 & d_{22} \\ I & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & I & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & I & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & I \end{bmatrix} \begin{bmatrix} x'_1 \\ y_1 \\ y_2 \\ v_1 \\ x_1 \\ x_2 \\ x_2 \\ u_1 \\ w_2 \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ x'_2 \\ y_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 & 0 & I & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & I & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x'_2 \\ v_2 \\ x'_1 \\ y_1 \\ y_2 \\ v_1 \\ x_1 \\ x_2 \\ u_1 \\ w_2 \end{bmatrix}$$

The factored state variable description is:

$$\begin{aligned} \begin{bmatrix} x'_1 \\ x'_2 \\ y_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 & 0 & I & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & I & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 & 0 & b_1 & 0 & 0 & A_2 & 0 & b_2 \\ 0 & 0 & d_{21} & 0 & 0 & c_2 & 0 & d_{22} \\ I & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & I & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & I & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & I \end{bmatrix} \begin{bmatrix} x'_1 \\ y_1 \\ y_2 \\ v_1 \\ x_1 \\ x_2 \\ x_2 \\ u_1 \\ w_2 \end{bmatrix} \\ &= \begin{bmatrix} I & 0 & 0 & 0 & 0 \\ 0 & 0 & b_1 & A_2 & b_2 \\ 0 & I & 0 & 0 & 0 \\ 0 & 0 & d_{21} & c_2 & d_{22} \end{bmatrix} \begin{bmatrix} B_2 & A_1 & 0 & B_1 & 0 \\ D_{12} & C_1 & 0 & D_{11} & 0 \\ D_{22} & C_2 & 0 & D_{21} & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & 0 & I \end{bmatrix} \begin{bmatrix} 0 & c_1 & 0 & d_{12} \\ I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ u_1 \\ w_2 \end{bmatrix} \\ &= \begin{bmatrix} A_1 & B_2c_1 & B_1 & B_2d_{12} \\ b_1C_2 & b_1D_{22}c_1 + A_2 & b_1D_{21} & b_1D_{22}d_{12} + b_2 \\ C_1 & D_{12}c_1 & D_{11} & D_{12}d_{12} \\ d_{21}C_2 & d_{21}D_{22}c_1 + c_2 & d_{21}D_{21} & d_{21}D_{22}d_{12} + d_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ u_1 \\ w_2 \end{bmatrix} \end{aligned}$$

1.13 Block processing and decimation filters

See *Roberts and Mullis* [129, Section 10.2]. Block processing digital filters are multi-input, multi-output (MIMO) filters which are equivalent to a single-input, single-output (SISO) filter. MIMO filters have the following advantages:

- parallel computation increases the output data rate
- output noise is reduced and other finite register effects are improved when compared to the corresponding SISO filter
- the number of multiplies per output is reduced when compared to the corresponding SISO filter.

In general, for a state variable filter with state updates every P samples:

$$\begin{bmatrix} x(k+P) \\ y'(k) \end{bmatrix} = \begin{bmatrix} A' & B' \\ C' & D' \end{bmatrix} \begin{bmatrix} x(k) \\ u'(k) \end{bmatrix}$$

where:

$$u'(k) = \begin{bmatrix} u(k) \\ u(k+1) \\ \vdots \\ u(k+P-1) \end{bmatrix}$$

$$y'(k) = \begin{bmatrix} y(k) \\ y(k+1) \\ \vdots \\ y(k+P-1) \end{bmatrix}$$

and:

$$A' = A^P$$

$$B' = [A^{P-1}B \quad A^{P-2}B \quad \cdots \quad B]$$

$$C' = \begin{bmatrix} C \\ CA \\ \vdots \\ CA^{P-1} \end{bmatrix}$$

$$D' = \begin{bmatrix} D & 0 & 0 & \cdots & 0 \\ CB & D & 0 & \cdots & 0 \\ CAB & CB & D & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ CA^{P-2}B & \cdots & \cdots & CB & D \end{bmatrix}$$

For example, if the block length is $P = 2$:

$$\begin{bmatrix} x(k+1) \\ y(k) \\ u(k+1) \end{bmatrix} = \begin{bmatrix} A & B & 0 \\ C & D & 0 \\ 0 & 0 & I \end{bmatrix} \begin{bmatrix} x(k) \\ u(k) \\ u(k+1) \end{bmatrix}, \text{ first update} \quad (1.14)$$

$$\begin{bmatrix} x(k+2) \\ y(k) \\ y(k+1) \end{bmatrix} = \begin{bmatrix} A & 0 & B \\ 0 & I & 0 \\ C & 0 & D \end{bmatrix} \begin{bmatrix} x(k+1) \\ y(k) \\ u(k+1) \end{bmatrix}, \text{ second update} \quad (1.15)$$

The factored state variable description of the block-length 2 filter is:

$$\begin{bmatrix} x(k+2) \\ y(k) \\ y(k+1) \end{bmatrix} = \begin{bmatrix} A & 0 & B \\ 0 & I & 0 \\ C & 0 & D \end{bmatrix} \begin{bmatrix} A & B & 0 \\ C & D & 0 \\ 0 & 0 & I \end{bmatrix} \begin{bmatrix} x(k) \\ u(k) \\ u(k+1) \end{bmatrix} = \begin{bmatrix} A^2 & AB & B \\ C & D & 0 \\ CA & CB & D \end{bmatrix} \begin{bmatrix} x(k) \\ u(k) \\ u(k+1) \end{bmatrix}$$

Roberts and Mullis [129, Table 10.2.1] list the number of multipliers-per-output for three classes of N -th order, block length P block processing state variable filters, reproduced in Table 1.1. If the filter is decimating then only a single output, $y(k)$, needs to be calculated in each block and the number of multipliers-per-output is reduced accordingly.

The Octave function *sv2block* converts a block length 1 state variable filter to a block length P state variable filter. The Octave function *svf* implements a MIMO state variable filter that can be applied to block filtering by rearranging the input and output matrixes appropriately. The Octave function *Abcd2cc* generates an *oct*-file implementation of a block processing state variable filter. The Octave script *Abcd2cc_test.m* tests the *oct*-file implementation of an 8-th order elliptic filter with block length 12

Filter structure	Number of multipliers per output	Optimal block length, P
Full state-space filter	$\frac{N^2}{P} + 2N + \frac{P+1}{2}$	$N\sqrt{2}$
m -th order cascaded sections	$\left(\frac{m}{P} + 2 + \frac{P+1}{2m}\right) N$	$m\sqrt{2}$
m -th order parallel sections	$\left(\frac{m}{P} + 2 + \frac{P-1}{2m}\right) N + 1$	$m\sqrt{2}$

Table 1.1: The number of multipliers for three classes of N -th order block processing filters. (See [129, Table 10.2.1]).

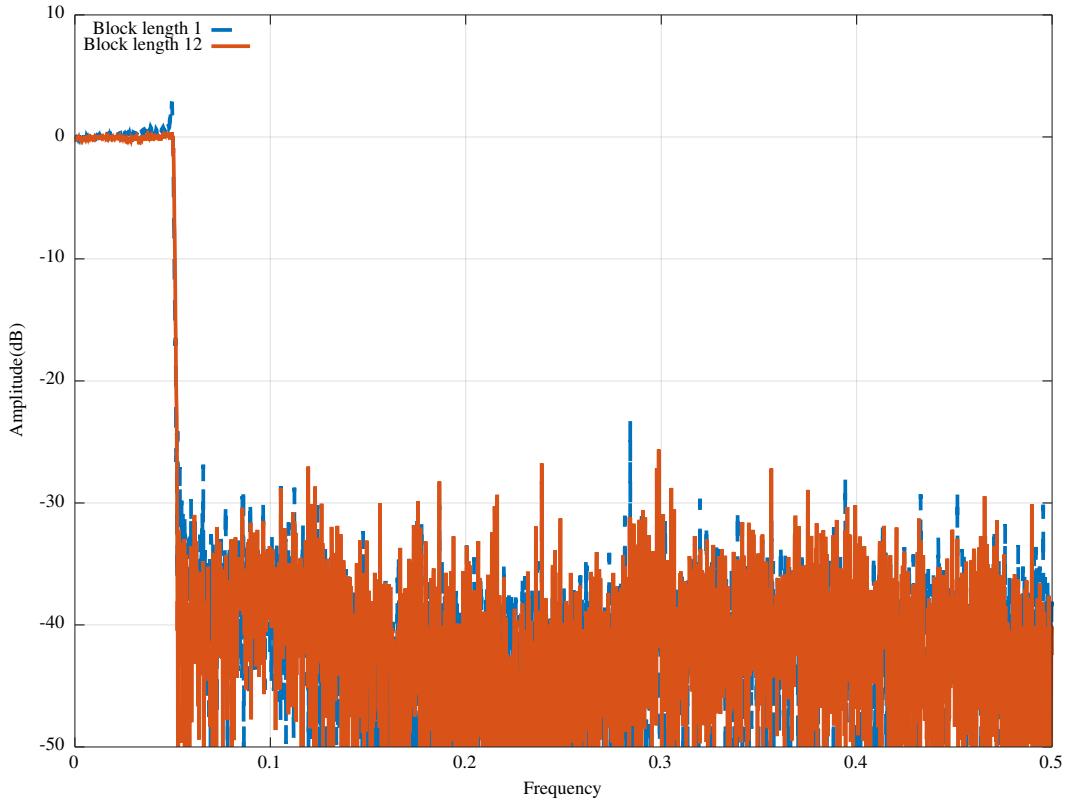

Figure 1.9: Simulated response of a 8-th order elliptic filter with 8-bit precision coefficients for block lengths of 1 and 12. The block length 12 filter is implemented as an *oct*-file.

and 8 bit coefficients. Figure 1.9 shows the overall simulated response and Figure 1.10 compares the passband responses. The pass-band response of the block length 12 filter is more accurate than that of the block length 1 filter. The noise gain^e of the block filter with truncated coefficients is accurately estimated by dividing the noise gain of the *untruncated* block length 1 filter by P . Use of the noise gain of the untruncated filter reflects the improvement in round-off noise performance obtained by block processing. The accuracy of the estimate of the noise gain of the truncated block length 1 filter improves when the number of bits is increased to 10. From Table 1.1, the number of multipliers per output is 81 for the block length 1 filter and 27.83 for the block length 12 filter.

^eSee Chapter 3.

Chapter 2

Frequency transformations of state variable filters

2.1 Frequency Transformations

See *Roberts and Mullis* [129, Section 6.7]. A *generalised band-pass* filter has a frequency response function $H(e^{j\theta})$ which is zero in each *stop-band* and one in each *pass-band*. Given a prototype low-pass filter $H(z)$ we wish to design a frequency transformation $F(z)$ such that the composition $G(z) = H(F(z))$ is a filter with the properties:

1. $F(z)$ should map the unit circle into itself, ie: $F(e^{j\phi}) = e^{j\theta(\phi)}$, so that $G(e^{j\phi}) = H(e^{j\theta(\phi)})$.
2. If $H(z)$ is stable and minimum phase, then $G(z)$ is stable and minimum phase. If λ is a pole (or zero) $G(z)$, then $F(\lambda)$ is a pole (or zero) of $H(z)$. Thus if $|\lambda| < 1$ implies $|F(\lambda)| < 1$ then these properties are preserved.

Consequently, the complex function $F(z)$ is a *frequency transformation* if

1. $|z| > 1 \Leftrightarrow |F(z)| > 1$
2. $|z| = 1 \Leftrightarrow |F(z)| = 1$
3. $|z| < 1 \Leftrightarrow |F(z)| < 1$

Products $F_1(z)F_2(z)$ of frequency transformations are frequency transformations. Compositions $F_1(F_2(z))$ of frequency transformations are also frequency transformations. If $F(z)$ is a frequency transformation, then $1/F(z)$ is a stable all-pass filter. In the composition $G(z) = H(F(z))$ the unit delay z^{-1} is replaced with the all-pass filter $[F(z)]^{-1}$. For IIR filter design $F(z)$ must be a rational function. A first order frequency transformation has the form:

$$F(z) = \pm \frac{z - \alpha}{1 - \alpha^* z} \quad |\alpha|^2 < 1$$

This is a frequency transformation since

$$\begin{aligned} |F(z)|^2 &= \frac{(z - \alpha)(z^* - \alpha^*)}{(1 - \alpha^* z)(1 - \alpha z^*)} \\ &= 1 + \frac{zz^* - 1 + \alpha\alpha^* - \alpha\alpha^*zz^*}{1 - \alpha z^* - \alpha^* z + \alpha\alpha^*zz^*} \\ &= 1 + \frac{[|z|^2 - 1][1 - |\alpha|^2]}{|1 - \alpha^* z|^2} \end{aligned}$$

Order n frequency transformations are known as *Blaschke products*

$$F(z) = \pm \prod_{i=1}^m \left(\frac{z - \alpha_i}{1 - \alpha_i^* z} \right) = \pm \frac{p(z)}{\tilde{p}(z)}$$

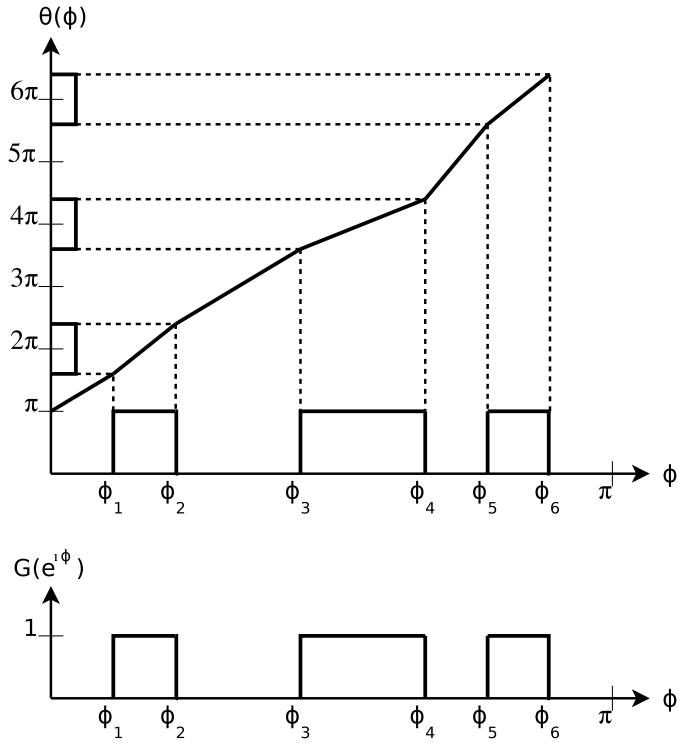

Figure 2.1: Frequency warping function (after *Roberts and Mullis* [129, Figure 6.7.2])

where

$$p(z) = \sum_{i=0}^n p_i z^{-i} = p_0 z^{-n} \prod_{i=1}^n (z - \alpha_i)$$

has roots $|\alpha_i| < 1$ and $\tilde{p}(z) = z^{-n} p(z^{-1})$.

Suppose the prototype $H(z)$ has cut-off frequency $\theta = \pi/2$ and $G(z)$ has the pass band edges shown in Figure 2.1 (where $G(z)$ is low-stop).

$F(z)$ must map the band edges as shown by the frequency warp $\theta(\phi)$. There are two cases:

$$\text{low-pass : } \begin{cases} F(1) = 1 \\ \theta(0) = 0 \\ \theta_k = \theta(\phi_k) = \left(k - \frac{1}{2}\right)\pi \end{cases}$$

$$\text{low-stop : } \begin{cases} F(1) = -1 \\ \theta(0) = \pi \\ \theta_k = \theta(\phi_k) = \left(k + \frac{1}{2}\right)\pi \end{cases}$$

Roberts and Mullis [129, Figure 6.7.3] show an algorithm for calculating the parameters of the frequency transformation $F(z)$. This algorithm is implemented by the Octave [68] function *phi2p*.

2.2 Frequency Transformation of the Transfer Function

See *Roberts and Mullis* [129, Problem 6.26]. Given a low-pass prototype:

$$\begin{aligned} H(z) &= \frac{\beta(z)}{\alpha(z)} \\ &= \frac{\sum_{k=0}^L \alpha_k z^{-k}}{\sum_{k=0}^L \beta_k z^{-k}} \end{aligned}$$

and a frequency transformation function

$$F(z) = \frac{p(z)}{\tilde{p}(z)}$$

where $p(z) = \sum_{k=0}^M p_k z^{-k}$ and $\tilde{p}(z) = z^{-M} p(z^{-1})$, find the filter

$$G(z) = H(\sigma F(z)) = \frac{b(z)}{a(z)}$$

where $\sigma = 1$ for low-pass and $\sigma = -1$ for low-stop.

First expand $a(z)$ and $b(z)$ in $\alpha(z)$, $\beta(z)$ and $p(z)$:

$$\begin{aligned} \frac{a(z)}{b(z)} &= \frac{\sum_{k=0}^{LM} a_k z^{-k}}{\sum_{k=0}^{LM} b_k z^{-k}} \\ &= \frac{\sum_{k=0}^L \alpha_k [\sigma p(z)/\tilde{p}(z)]^{-k}}{\sum_{k=0}^L \beta_k [\sigma p(z)/\tilde{p}(z)]^{-k}} \\ &= \frac{\sum_{k=0}^L \alpha_k [\sigma z^{-M} p(z^{-1})]^k [p(z)]^{L-k}}{\sum_{k=0}^L \beta_k [\sigma z^{-M} p(z^{-1})]^k [p(z)]^{L-k}} \end{aligned}$$

A common factor of $[p(z)]^L$ has been introduced. Next choose $N \geq LM+1$ and define the following *Discrete Fourier Transform* pairs:

$$\begin{bmatrix} p_0 & \cdots & p_M & 0 & \cdots & 0 \end{bmatrix} \xrightarrow{DFT} \begin{bmatrix} P(0) & P(1) & \cdots & P(N-1) \end{bmatrix} \\ \begin{bmatrix} a_0 & \cdots & a_{LM} & 0 & \cdots & 0 \end{bmatrix} \xrightarrow{DFT} \begin{bmatrix} A(0) & A(1) & \cdots & A(N-1) \end{bmatrix} \\ \begin{bmatrix} b_0 & \cdots & b_{LM} & 0 & \cdots & 0 \end{bmatrix} \xrightarrow{DFT} \begin{bmatrix} B(0) & B(1) & \cdots & B(N-1) \end{bmatrix} \end{math>$$

where

$$\begin{aligned} A(n) &= \sum_{k=0}^{N-1} a_k W_N^{-nk} \\ &= a(W_N^n) \\ &= \sum_{k=0}^L \alpha_k \sigma^k W_N^{-knM} e^{-2k \arg\{P(n)\}} \{P(n)\}^L \\ &= \alpha(e^{i\theta_n}) \{P(n)\}^L \end{aligned}$$

and

$$\theta_n = \frac{2\pi n M}{N} + \left(\frac{1-\sigma}{2} \right) \pi + 2 \arg\{P(n)\}$$

Here $W_N = e^{i\frac{2\pi}{N}}$ and \arg means “angle of”. Similarly:

$$B(n) = \beta(e^{i\theta_n}) \{P(n)\}^L$$

This algorithm is implemented by the Octave function *tfp2g.m*.

2.3 Frequency Transformations of State Variable Filters

See *Mullis and Roberts* [21, Section 6.7]. Given a (usually low-pass) prototype filter $H(z)$ parameterised by the state variable description $\{A, b, c, d\}$ construct the filter $G(z) = H(F(z))$ where

$$F(z) = \pm \prod_{i=1}^m \left(\frac{z - \alpha_i^*}{1 - \alpha_i z} \right), \quad |\alpha_i| < 1$$

If the order of $H(z)$ is n then the order of $G(z)$ is mn . The map $z \rightarrow F(z)$ preserves the disk $|z| < 1$, the circle $|z| = 1$ and the set $|z| > 1$ since

$$1 - \left| \frac{z - \alpha^*}{1 - \alpha z} \right|^2 = \frac{(1 - |z|^2)(1 - |\alpha|^2)}{|1 - \alpha z|^2}$$

Therefore if $H(z)$ is stable (minimum phase) then $G(z)$ is stable (minimum phase). We want to find the matrices $\mathfrak{A}, \mathfrak{B}, \mathfrak{C}, \mathfrak{D}$ such that

$$\mathfrak{D} + \mathfrak{C}(zI - \mathfrak{A})^{-1} \mathfrak{B} = G(z) = H(F(z))$$

Let matrices $\{\alpha, \beta, \gamma, \delta\}$ parameterise the filter $1/F(z)$ so that

$$\frac{1}{F(z)} = \delta + \gamma(zI - \alpha)^{-1} \beta$$

Note that $1/F(z)$ is a stable, all-pass filter.

A heuristic construction of $H(F(z))$ follows. The filter $1/F(z)$ replaces each delay branch in the original filter, $H(z)$, so for a $m \times n$ matrix $S(k)$

$$\begin{aligned} S(k+1) &= \alpha S(k) + \beta [Ax(k) + bu(k)]^T \\ x(k) &= S^T(k) \gamma^T + \delta [Ax(k) + bu(k)] \\ y(k) &= cx(k) + du(k) \end{aligned}$$

Eliminating $x(k)$ gives

$$\begin{aligned} S(k+1) &= \alpha S(k) + \beta \gamma S(k) \left[A(I - \delta A)^{-1} \right]^T + \beta \left[(I - \delta A)^{-1} \right]^T u(k) \\ y(k) &= \gamma S(k) \left[c(I - \delta A)^{-1} \right]^T + \left[d + \delta c(I - \delta A)^{-1} b \right] u(k) \end{aligned}$$

Define $V(X)$ as the vector formed by stacking the columns of X and define $G \otimes F$ as the *Kronecker product*^a, $\{G_{ij}F\}$, of the matrixes G and F . Then:

$$\begin{aligned} V(S(k+1)) &= \mathfrak{A}V(S(k)) + \mathfrak{B}u(k) \\ y(k) &= \mathfrak{C}V(S(k)) + \mathfrak{D}u(k) \end{aligned}$$

where

$$\begin{aligned} \mathfrak{A} &= I \otimes \alpha + A(I - \delta A)^{-1} \otimes \beta \gamma \\ \mathfrak{B} &= (I - \delta A)^{-1} b \otimes \beta \\ \mathfrak{C} &= c(I - \delta A)^{-1} \otimes \gamma \\ \mathfrak{D} &= d + \delta c(I - \delta A)^{-1} b \end{aligned}$$

and

$$H(F(z)) = \mathfrak{D} + \mathfrak{C}(zI - \mathfrak{A})^{-1} \mathfrak{B} \quad (2.1)$$

Mullis and Roberts [21] give a direct proof. Start with the identity:

$$(fI - A)b \otimes \beta = f \left[b \otimes \beta - Ab \otimes \beta \left(\frac{1}{f} \right) \right]$$

^aDefine $V(X)$ as the vector formed by stacking the columns of X . Suppose the matrix product FXG^T is defined. This represents a linear transformation applied to X . When this transformation is arranged as a vector

$$V(FXG^T) = [G \otimes F]V(X)$$

where $G \otimes F$ is defined as the *Kronecker product*, $\{G_{ij}F\}$, of matrices G and F . The Kronecker product is defined for any two matrices and satisfies the following:

$$\begin{aligned} [A \otimes B][C \otimes D] &= (AC) \otimes (BD) \\ (A + B) \otimes (C + D) &= A \otimes C + A \otimes D + B \otimes C + B \otimes D \\ [A \otimes B]^{-1} &= A^{-1} \otimes B^{-1} \\ [A \otimes B]^T &= A^T \otimes B^T \end{aligned}$$

By convention Kronecker products are performed *after* ordinary matrix products and *before* matrix addition.

Where, for convenience the scalar $F(z) = f$. So

$$\begin{aligned} b \otimes \beta &= f \left[(fI - A)^{-1} b \otimes \beta - A (fI - A)^{-1} b \otimes \beta \left(\delta + \gamma (zI - \alpha)^{-1} \beta \right) \right] \\ &= f [I \otimes (zI - \alpha) - \delta A \otimes (zI - \alpha) - A \otimes \beta \gamma] \cdot \left[(fI - A)^{-1} b \otimes (zI - \alpha)^{-1} \beta \right] \\ &= [(I - \delta A) \otimes (zI - \alpha) - A \otimes \beta \gamma] \cdot \left[f (fI - A)^{-1} b \otimes (zI - \alpha)^{-1} \beta \right] \end{aligned}$$

Therefore

$$\begin{aligned} \mathfrak{B} &= (I - \delta A)^{-1} b \otimes \beta \\ &= \left[I \otimes (zI - \alpha) - (I - \delta A)^{-1} A \otimes \beta \gamma \right] \cdot \left[f (fI - A)^{-1} b \otimes (zI - \alpha)^{-1} \beta \right] \\ &= (zI - \mathfrak{A}) \left[f (fI - A)^{-1} b \otimes (zI - \alpha)^{-1} \beta \right] \end{aligned}$$

so, substituting $(zI - \mathfrak{A})^{-1} \mathfrak{B}$

$$\begin{aligned} \mathfrak{D} + \mathfrak{C} (zI - \mathfrak{A})^{-1} \mathfrak{B} &= \left[d + \delta c (I - \delta A)^{-1} b \right] + \left[c (I - \delta A)^{-1} \otimes \gamma \right] \cdot \left[f (fI - A)^{-1} b \otimes (zI - \alpha)^{-1} \beta \right] \\ &= d + \delta c (I - \delta A)^{-1} b + f \left[c (I - \delta A)^{-1} (fI - A)^{-1} b \right] \cdot \left[\gamma (zI - \alpha)^{-1} \beta \right] \\ &= d + c (I - \delta A)^{-1} \left[\delta (fI - A) + f \left(\frac{1}{f} - \delta \right) I \right] (fI - A)^{-1} b \\ &= d + c (fI - A)^{-1} b \\ &= H(f) \\ &= H(F(z)) \end{aligned}$$

This algorithm is implemented by the Octave function *tfp2Abcd*.

2.4 An example: frequency transformations of a 5-th order elliptic filter

The Octave script *tfp2g_test.m* shows examples of frequency transformations of a 5th order elliptic low-pass filter. Figure 2.2 shows the prototype filter. Figure 2.3 shows the result of a low-pass to low-pass transformation. Figure 2.4 shows the result of a low-pass to high-pass transformation. Figure 2.5 shows the result of a low-pass to band-pass transformation. Figure 2.6 shows the result of a low-pass to triple band-stop transformation.

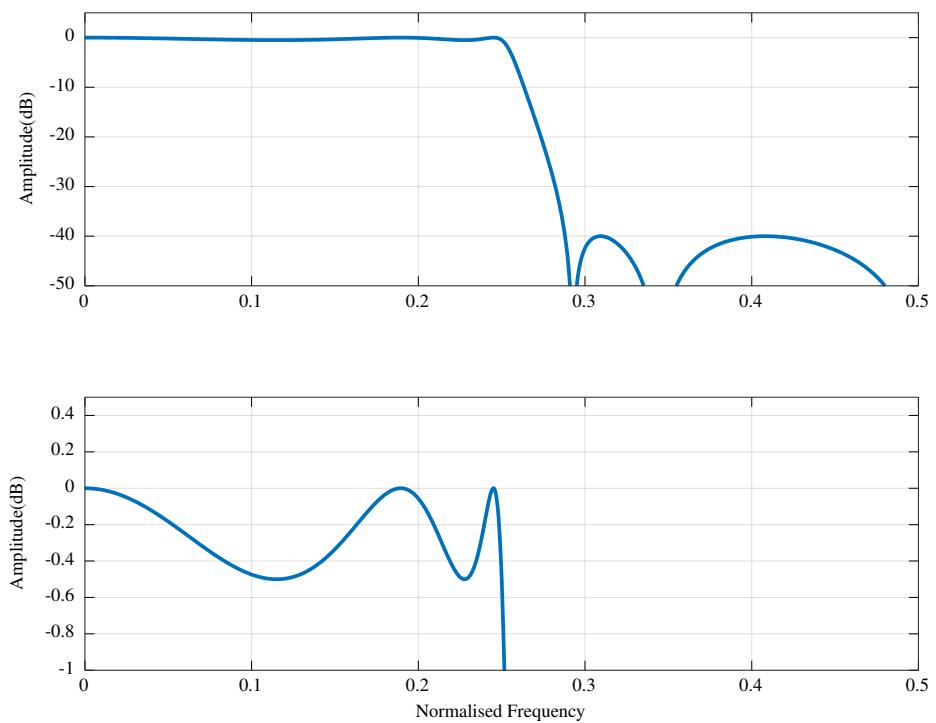

Figure 2.2: Prototype 5-th order elliptic low-pass filter

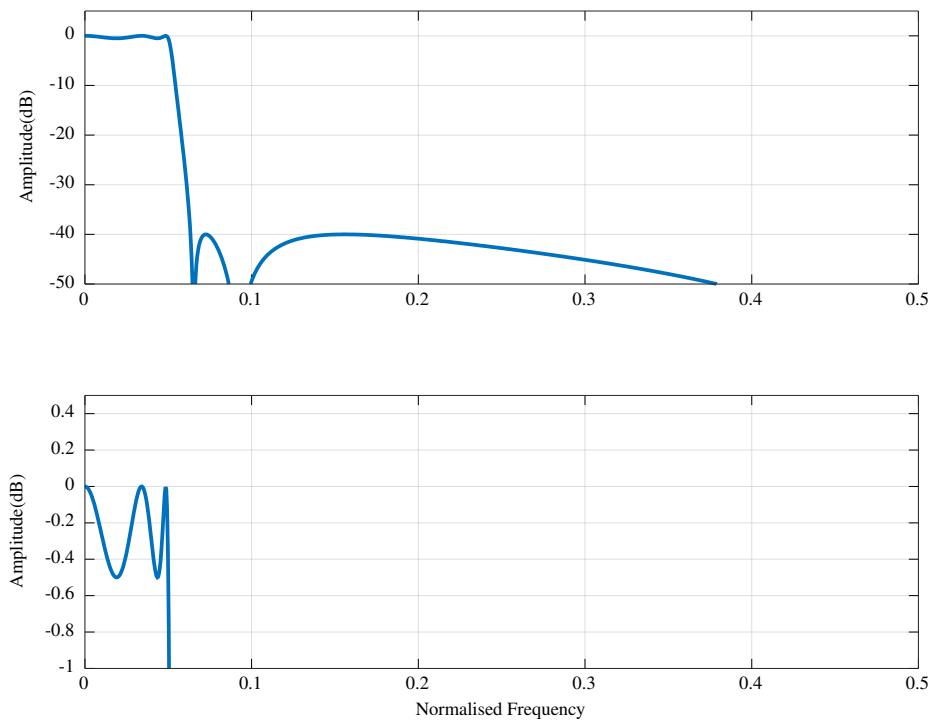

Figure 2.3: Low-pass to low-pass transformation of a 5-th order elliptic low-pass filter

Chapter 3

Round-off noise in state variable filters

This chapter is based on Chapter 9 of *Roberts and Mullis* [129].

3.1 Quantisation noise in digital filters

The binary number generated by an ADC is assumed to be a fixed point number. Most often this number is represented in 2's complement format because that is easily implemented. The 2's complement representation of a real number, r , in a finite length register of B bits is:

$$[r]_Q = \Delta \left(-b_0 + \sum_{m=1}^{B-1} b_m 2^{-m} \right)$$

where:

$$\begin{aligned}\Delta &\leq r < \Delta \\ b_0 &= 1 \text{ for } r \leq 0 \\ b_0 &= 0 \text{ for } r \geq 0\end{aligned}$$

Here Δ is the maximum voltage represented and b_0 is the sign bit. The quantization step size is $q = \Delta 2^{-B+1}$. If the quantiser rounds to the nearest integer multiple of q then the error in the representation of r can be considered to be uncorrelated from sample to sample and uniformly distributed in the range $(-\frac{q}{2}, \frac{q}{2})$ with variance^a $\sigma_e^2 = \frac{q^2}{12}$. This assumes that the frequency spectrum of the input, $u(k)$, of the quantiser is reasonably broad and that the probability density function of $u(k)$ is broad relative to q so that several quantization levels are crossed between samples of $u(k)$. The signal-to-noise ratio obtained depends on the statistics of both the quantization noise and the signal that is quantised, $u(k)$. If $u(k)$ is uniformly distributed over the range $[-\Delta, \Delta]$ then the variance of $u(k)$ is $\sigma_u^2 = \frac{1}{3}$ and the required number of bits, B , to obtain a signal to noise ratio of SN_Q is $b = \frac{\log_2 SN_Q}{2}$.

2's complement arithmetic does rounding-toward-zero rounding, also called magnitude truncation. The quantisation error is uniformly distributed in the range $(-q, q)$ with variance $\sigma_e^2 = \frac{q^2}{3}$. For positive inputs the error is negative and for negative inputs the error is positive. This distribution corresponds to a step input of $\frac{q}{2}$ at the state round off noise error input to the filter. Modern digital signal processing ICs use a few gates to provide a rounding-to-nearest arithmetic mode. If this is not present software rounding may be required to give adequate noise performance. The results presented in the following sections assume the rounding-to-nearest quantiser. Note that the 2's complement overflow characteristic has the useful property that immediate overflows in an accumulator cancel whenever the resulting sum is in range. An example will demonstrate the effect of the rounding-to-minus-infinity quantiser.

^aThe probability density function of the quantisation error of r , e , is $p_e(x) = q^{-1}$ and the mean error is $\mu_e = 0$. The variance of the error is the *second central moment* of the pdf:

$$\sigma_e = E\{[e - \mu_e]^2\} = \int_{-\infty}^{\infty} (x - \mu_e)^2 p_e(x) dx = \int_{-q/2}^{q/2} \frac{x^2}{q} dx = \frac{q^2}{12}$$

3.2 Limit-cycle oscillations in digital filters

See *Roberts and Mullis* [129, Section 9.3]. If numbers are represented as 2's complement integers and there is no provision for explicitly detecting and correcting overflows then, depending on how the filter is scaled, there is a possibility that internal registers will overflow. What happens then depends on:

- the nature of the input
- the filter realization
- the number representation used in the filter
- the overflow characteristic used in the filter

The direct form filter has the minimum number of multipliers for a second order filter. However, with a 2's complement overflow characteristic the output of the filter after an overflow can, depending on the poles of the filter, become independent of the input sequence. This condition is called overflow oscillation. A second order direct form filter is free of overflow oscillations provided:

$$|\alpha_1| + |\alpha_2| \leq 1$$

where $1 + \alpha_1 z^{-1} + \alpha_2 z^{-2}$ is the denominator of the transfer function. Many other realizations are free of overflow oscillations by design.

3.3 State variable filters and wide sense stationary inputs

3.3.1 The filter state covariance matrix

Assume a causal filter $H(z)$ driven by white, wide-sense stationary unit variance white noise inputs, $u(k)$. The covariance matrix of the filter state is:

$$\begin{aligned} K &= E\{x(k)x^T(k)\} \\ &= E\{x(k+1)x^T(k+1)\} \\ &= E\{(Ax(k) + Bu(k))(Ax(k) + Bu(k))^T\} \\ &= E\{Ax(k)x^T(k)A^T + Bu(k)u^T(k)B^T\} \\ &= AKA^T + BB^T \end{aligned}$$

This is known as a *discrete Lyapunov equation*. Alternatively, since

$$x(k) = \sum_{l=0}^{\infty} A^l Bu(k-l-1)$$

the state covariance matrix is

$$K = \sum_{m=0}^{\infty} \sum_{l=0}^{\infty} A^l B r_{uu}(l-m) (A^m B)^T$$

For unit variance white inputs

$$K = \sum_{l=0}^{\infty} (A^l B) (A^l B)^T$$

Algorithm 3.1 is a simple recursive calculation of the covariance matrix implemented in the Octave function *dlyap_recursive*.

Alternative methods for calculating the covariance matrix are:

- find the auto-correlation sequence of the characteristic equation of the state transition matrix with the inverse-Levinson recursion. See *Roberts and Mullis* [129, Section 9.11, p. 393]. The Octave function *dlyap_levinson* implements this solution.
- use Hammarling's solution of the discrete Lyapunov equation [140]. The Octave *Control* package contains the *dlyap* function that calls functions from an open-source version of the *SLICOT* library [34] to implement Hammarling's algorithm.

Algorithm 3.1 Recursive calculation of the covariance matrix

```

 $F \leftarrow A$ 
 $K \leftarrow BB^T$ 
repeat
     $K \leftarrow FKF^T + K$ 
     $F \leftarrow F^2$ 
until  $F = 0$ 

```

3.3.2 The output response to white noise in a state variable

The unit pulse response is a cross-correlation of the input and output

$$h(k) = E\{y(k+l)u(l)\}$$

The autocorrelation sequence for the output is

$$\begin{aligned} r_{yy}(k) &= E\{y(k+l)y(l)\} \\ &= \sum_{l=0}^{\infty} h(k+l)h(l) \end{aligned}$$

Using a state variable description

$$h(k) = \begin{cases} 0 & k < 0 \\ D & k = 0 \\ CA^{k-1}B & k > 0 \end{cases} \quad \text{DFT} \quad H(e^{j\theta}) = D + C(e^{j\theta}I - A)^{-1}B$$

Since

$$r_{yy}(k) \quad \text{DFT} \quad S_{yy}(\theta) = |H(e^{j\theta})|^2$$

we can express the output autocorrelation sequence directly from $\{A, B, C, D\}$. The output autocorrelation sequence is

$$\begin{aligned} r_{yy}(k) &= E\{y(k+l)y^T(l)\} \\ &= E\{(Cx(k+l) + Du(k+l))(Cx(l) + Du(l))^T\} \\ &= E\{Cx(k+l)x^T(l)C^T + Du(k+l)x^T(l)C^T + Cx(k+l)u^T(l)D^T + Du(k+l)u^T(l)D^T\} \end{aligned}$$

The first term is

$$\begin{aligned} E\{x(k+l)x^T(l)\} &= E\left\{\left(\sum_{m=0}^{\infty} A^m Bu(k+l-m-1)\right)\left(\sum_{m'=0}^{\infty} A^{m'} Bu(l-m'-1)\right)^T\right\} \\ &= \sum_{m=0}^{\infty} \sum_{m'=0}^{\infty} (A^m B)(A^{m'} B)^T r_{uu}(k-m-m') \\ &= \sum_{m=0}^{\infty} A^k A^m B (A^m B)^T \\ &= A^k K \end{aligned}$$

where we have used the fact that $r_{uu}(k-m+m') = \delta(k-m+m')$. The cross-correlation between the state and a white noise input is

$$\begin{aligned} E\{x(k+l)u(l)\} &= E\left\{\sum_{j=0}^{\infty} A^j Bu(k+l-j-1)u(l)\right\} \\ &= \sum_{j=0}^{\infty} A^j B \delta(k-j-1) \\ &= \begin{cases} A^{k-1} B & k > 0 \\ 0 & k \leq 0 \end{cases} \end{aligned}$$

(This is also the unit-pulse response from the input to internal states.) The present state is uncorrelated with future inputs so the term containing $u(k+l)x^T(k)$ is zero. Finally,

$$\begin{aligned} r_{yy}(k) &= CA^k KC^T + CA^{k-1} BD^T \\ &= CA^k KC^T + h(k) D^T \end{aligned}$$

The energy in the unit-pulse response is given by

$$\begin{aligned} r_{yy}(0) &= E\{y^2(k)\} \\ &= \sum_{l=0}^{\infty} h^2(l) \\ &= \frac{1}{2\pi} \int_{-\pi}^{\pi} |H(e^{j\theta})|^2 d\theta \\ &= D^2 + CKC^T \end{aligned}$$

3.3.3 Scaling State Variable Filters To Avoid Overflow

Round off noise is the dominant component of output error in digital filters only when overflows in internal registers are negligible. Overflows are avoided by properly scaling the realization. For a fixed point number representation the range of internal variables is:

$$|v(k)| \leq \Delta$$

The magnitude of Δ depends on the quantization step size and the number of bits. The unit pulse response from the input, $u(k)$ to an internal variable, $v(k)$, can be written:

$$v(k) = (f * u)(k)$$

where f is the unit pulse response from the input to $v(k)$ and $*$ is the convolution operator. The range of values of v depends on the nature of the input and on the sequence f .

For sinusoidal inputs:

$$\begin{aligned} u(k) &= \cos(k\theta) \\ |v(k)| &\leq \max |F(e^{j\theta})| \end{aligned}$$

where F is the transfer function from u to v .

For bounded inputs:

$$\begin{aligned} |u(k)| &\leq 1 \\ |v(k)| &\leq \sum_l |f(l)| = \|f\|_1 \end{aligned}$$

The right side of the expression for the range of v is known as the l_1 -norm of f . These are called “bang-bang” controller inputs in control theory. For filter design the l_1 norm is usually far too conservative.

For finite energy inputs:

$$\begin{aligned} \sum_{l \leq k} u^2(l) &\leq 1 \\ |v(k)| &\leq \left[\sum_l f^2(l) \right]^{\frac{1}{2}} = \|f\|_2 \end{aligned}$$

The right side of the expression for the range of v is known as the l_2 -norm of f .

To reconcile these bounds on the range of v with the constraint on the size of v given above we must constrain the “gain” of the unit-pulse response sequences for the internal variables. The l_2 -norm scaling rule is:

$$\delta \|f\|_2 = \delta \left[\sum_l f^2(l) \right]^{\frac{1}{2}} = 1$$

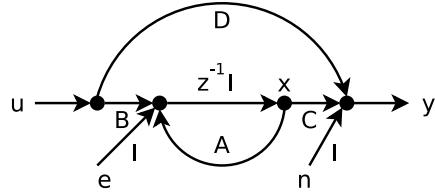

Figure 3.1: Signal flow graph of round-off noise of the state variable

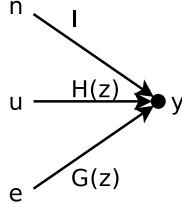

Figure 3.2: Signal flow graph of round-off noise at the filter output

The parameter δ is chosen subjectively. It can be interpreted as the number of standard deviations representable in the register containing v if the input is unit-variance white noise. A good value for δ is 4.

The diagonal components of the state variable covariance matrix, K , given above are related to the l_2 -norm for each state variable, $x(k)$, by:

$$K_{ii} = \sum_{k=0}^{\infty} f_i^2(k) = \|f_i\|_2$$

so the scaling constraint applied to the i -th component of the state vector is:

$$\delta \sqrt{K_{ii}} = 1, \quad i = 1, 2, \dots, n$$

This can be achieved by applying the coordinate transformation:

$$T^{-1} = \text{Diag} \left[\frac{1}{t_1}, \dots, \frac{1}{t_n} \right]$$

where:

$$t_i = \delta \sqrt{K_{ii}}, \quad i = 1, 2, \dots, n$$

A geometric interpretation of scaling is as follows: For unit variance stationary Gaussian inputs the set of values of the state variables $\{x : x^T K^{-1} x \leq 1\}$ represents the “one standard deviation error ellipsoid” in the filter state

3.4 Estimation of output round-off noise in state variable filters

The z-domain state variable equations with round off noise inputs can be represented by the following signal flow graph shown in Figure 3.1. Where e models the round off noise due to calculation of the state vector, x , and n models the round off noise due to calculation of the output, y . The state variable difference equations for the flow graph are:

$$\begin{aligned} x(k+1) &= Ax(k) + Bu(k) + e(k) \\ y(k) &= Cx(k) + Du(k) + n(k) \end{aligned}$$

The contribution of e to the state vector, x , is usually ignored when the filter realization is scaled. The round off noise at the output can be modeled as shown in Figure 3.2. Where:

$$\begin{aligned} H(z) &= D + C(zI - A)^{-1}B \\ G(z) &= C(zI - A)^{-1} \\ g(k) &= \begin{cases} 0 & k \leq 0 \\ CA^{k-1} & k > 0 \end{cases} \end{aligned}$$

$G(z)$ is a vector of transfer functions from each state to the output. $g(k)$ is a vector of unit pulse responses, one for each state. If we call σ_i^2 the variance of that part of the output which is the response to $e(k)$, then:

$$\sigma_i^2 = \sigma_e^2 \sum_{k=1}^{\infty} g_i^2(k) = \sigma_e^2 \|g_i\|^2$$

Recall that q is the quantization step size and for a rounding-to-nearest characteristic $\sigma_e^2 = \frac{q^2}{12}$.

These estimates assume that the state variables are truncated after accumulation (ie: a double length accumulator is used).

In a similar fashion to the covariance matrix, K , of the state vector, the energy in the sequence g_i can be characterised by the matrix, W :

$$\begin{aligned} W &= E \left\{ g_i(k) g_i(k)^T \right\} \\ &= \sum_{k=0}^{\infty} (CA^k)^T (CA^k) \\ &= A^T WA + C^T C \end{aligned}$$

This is also a discrete *Lyapunov* equation and can be solved in the same manner as the equation for the state covariance matrix, K . The matrixes K and W are often called the *controllability Gramian* and *observability Gramian*, respectively. The Octave function *KW.m* returns both K and W given the state variable description $\{A, B, C, D\}$. The user can select the algorithm used to solve the corresponding discrete *Lyapunov* equation. The default algorithm uses the Octave function *dlyap* if it is found and the *Levinson* recursion otherwise.

The output noise variance due to round-off noise in calculating the i -th state can be written:

$$\sigma_i^2 = \sigma_e^2 W_{ii} \quad i = 1, \dots, n$$

After the filter is scaled, the total output error due to round off noise in the calculation of the state vector is:

$$\sigma_{total}^2 = \sigma_e^2 \delta^2 \sum_{i=1}^n W_{ii} K_{ii}$$

W_{ii} and K_{ii} are those for the unscaled filter. The sum $\sum_{i=1}^n W_{ii} K_{ii}$ is known as the “noise gain” of the filter realization. It is invariant under a diagonal (or scaling) coordinate transformation. Under a general coordinate transform, T :

$$\{A, B, C, D, K, W\} \leftarrow \{T^{-1}AT, T^{-1}B, CT, T^{-1}KT^{-T}, T^TWT\}$$

The other sources of output noise variance are those due to the input quantization and the round off in calculating the output. Neither term depends on the filter realization. Output roundoff contributes the amount:

$$\sigma_{other}^2 = \sigma_e^2 \sum_{j=1}^m \|g_j\|_2^2$$

to the output noise. m is the number of non-state variable summation nodes, g_j is the unit pulse response from node j to the output and the quantisation step size at the output and at each node is assumed to be the same ie: the word lengths used are the same for each state.

The following result can be used to calculate the l_2 -norm of a transfer function, $H(z)$, with unit pulse response $h(k)$ and state variable representation $\{A, B, C, D\}$:

$$\|h\|_2^2 = D^2 + CKC^T \tag{3.1}$$

3.4.1 Rounding-to-minus-infinity quantisation noise

As stated in Section 3.1, the results for round-off noise shown above assume rounding-to-nearest rounding. With rounding-to-nearest rounding, the quantisation error is assumed to be uniformly distributed in the range $(-\frac{q}{2}, \frac{q}{2})$ with variance $\frac{q^2}{12}$, where q is the quantisation step size. For rounding-to-minus-infinity, the quantisation error is assumed to be uniformly distributed in the range $(0, q)$ with variance $\frac{q^2}{3}$. Consequently, rounding-to-minus-infinity rounding of the state variables is equivalent to adding a step of $\frac{q}{2}$ at the output of each state. The Octave script *gkstep_test.m* demonstrates the effect of using rounding-to-minus-infinity rounding in a 3rd order Butterworth filter with cut-off frequency $0.05f_S$. The Butterworth filter is globally optimised so that

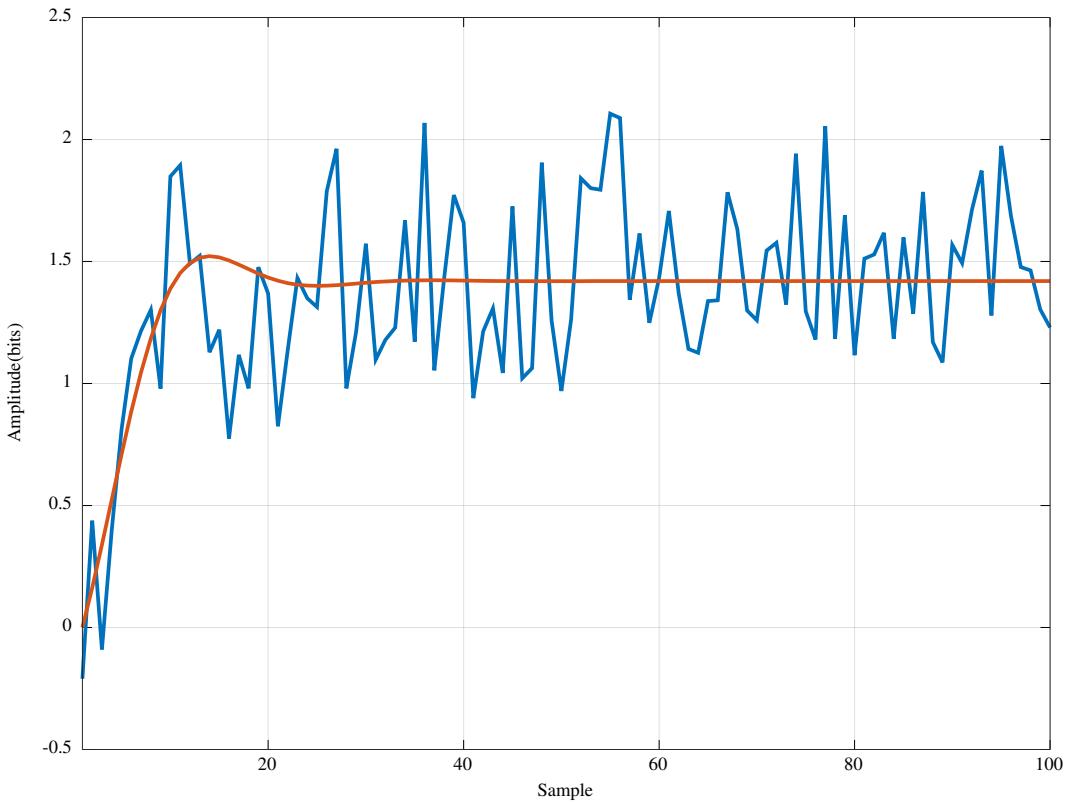

Figure 3.3: Summed state-to-output step response superimposed on the output quantisation noise of a 3rd order Butterworth filter due to rounding-to-minus-infinity at each state.

Algorithm 3.2 Minimisation of the noise gain

If K and W are two n -by- n real symmetric positive definite matrices then:

$$\left[\frac{1}{n} \sum_{i=1}^n K_{ii} W_{ii} \right]^{\frac{1}{2}} \geq \frac{1}{n} \sum_{i=1}^n \mu_i$$

where μ_i^2 are the eigenvalues of the product KW . Equality holds if and only if for some diagonal matrix D :

$$K = DWD$$

and $K_{ii}W_{ii} = K_{jj}W_{jj}$ for all i and j .

the states are equally scaled. The quantisation noise at the filter output is due to the filtered state variable quantisation noise in addition to the quantisation noise of the output calculation. The latter has a mean value of $\frac{q}{2}$. The state-to-filter-output unit impulse response has been given above. The state-to-filter-output step response is the sum over time of the impulse response. The expected step response at the filter output can be estimated as the sum of the state-to-filter-output step responses of each of the state variables. Figure 3.3 shows the simulated filtered state variable quantisation noise at the output of the filter superimposed on the summed state-output-to-filter-output step response to a step of $\frac{q}{2}$ at each state variable.

The rounding-toward-minus-infinity rounding error is not signal dependent. On the other hand, with the 2's-complement rounding-toward-zero rounding, the offset follows the sign of the input signal. The additional signal dependent quantisation noise introduced by rounding-toward-zero can significantly degrade filter noise performance.

3.5 Minimization of round-off noise in the calculation of the state vector

Minimising the noise gain minimises the round off noise. *Mullis and Roberts* [22] prove Algorithm 3.2 for equal word-length filters.

Algorithm 3.3 finds a coordinate transformation, T , that optimises the round-off noise of fixed point, equal wordlength state-variable filters given the K and W matrices. Algorithm 3.3 is implemented in the Octave function *optKW.m*.

Algorithm 3.3 Optimisation of the noise gain

1. Diagonalise K and W :

Since K and W are real, symmetric and positive definite, a decomposition into $W = U_1 D_1 U_1^T$ exists. Here U_1 is real and unitary (ie: $U_1^\dagger U_1 = I$, where \dagger means conjugate transpose) and D_1 is diagonal with real, positive elements. Recall that for non-singular matrices $(AB)^{-1} = B^{-1}A^{-1}$ and $(AB)^T = B^T A^T$. Let $T_1 = U_1 D_1^{-\frac{1}{2}}$ then

$$W_1 = T_1^T W T_1 = I$$

$$K_1 = T_1^{-1} K (T_1^{-1})^T = U_2 D_2 U_2^T$$

where U_2 is real and unitary and D_2 is diagonal with real, positive elements. Let $T_2 = T_1 U_2 D_2^{\frac{1}{4}}$ then

$$W_2 = T_2^T W T_2 = D_2^{\frac{1}{2}}$$

$$K_2 = T_2^{-1} K (T_2^{-1})^T = D_2^{\frac{1}{2}}$$

2. Balance $D_2^{\frac{1}{2}}$:

Now find a unitary transformation, U_3 , for which the diagonal elements of $U_3^T D_2^{\frac{1}{2}} U_3$ are nearly equal. U_3 can be found as a sequence of rotations that replace the largest and smallest diagonal elements of $D_2^{\frac{1}{2}}$ with their average. In two dimensions:

$$\begin{bmatrix} x' & y' \\ y' & z' \end{bmatrix} = \begin{bmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{bmatrix} \begin{bmatrix} x & y \\ y & z \end{bmatrix} \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix}$$

Expand the matrix product and set $x' = z'$ so that

$$\tan 2\theta = \frac{z - x}{2y}$$

After eliminating y from x' and z'

$$x' = z' = \frac{x + z}{2}$$

3. The optimising transform:

$$T = U_1 D_1^{-\frac{1}{2}} U_2 D_2^{\frac{1}{4}} U_3$$

The globally optimised state variable filter has $\mathcal{O}(n^2)$ coefficients. An alternative structure such as a lattice filter or a cascade of lower-order filters has fewer coefficients, $\mathcal{O}(n)$, but will have a larger than optimal noise gain. The noise gain for a non-optimal filter may be improved by distributing bits unevenly between the states. *Mullis and Roberts* [22, Section IV] show that if the state wordlengths are B_i with

$$\sum_{i=1}^n B_i = nB$$

and the quantisation step size for each state is

$$q = 2^{-B_i+1}$$

then the choice of B_i is optimised by setting

$$\frac{K_{ii}W_{ii}}{2^{2B_i}} = c$$

where c is a constant. Each B_i is given by

$$B_i = B + \frac{1}{2} \log_2 K_{ii}W_{ii} - \frac{1}{2n} \sum_{j=1}^n \log_2 K_{jj}W_{jj} \quad (3.2)$$

The optimal output noise is then:

$$\sigma_{total}^2 = \left[\frac{n}{3} \left(\frac{\delta}{2^B} \right)^2 \right] \left[\prod_{i=1}^n W_{ii} K_{ii} \right]^{\frac{1}{n}}$$

3.6 Coefficient sensitivity

An additional effect of the use of finite length registers is the quantization of the filter parameters. This appears as a deterministic change in the filter transfer function. In fact, the sensitivities of the transfer function to the state variable coefficients are bounded reasonably tightly by the noise-gain. This means that low round off noise and low coefficient sensitivity generally occur together in digital filters. In general, finite register effects become more severe as the poles of the filter cluster together. The ratio of cut-off frequency, f_c , to sample rate, f_S , is a useful measure of this clustering. For small values the finite register effects determine the realization chosen.

3.7 Factored state variable filters and wide sense stationary inputs

The estimate of round-off noise shown in Section 3.4 only applies to the state variables and does not include the round-off noise due to arithmetic operations at other nodes in the filter. The *factored* state variable description can be used to find the variance of any variable in the realisation. Let

$$q_0(k) = \begin{bmatrix} x(k) \\ u(k) \end{bmatrix}$$

then the covariance matrix for $q_0(k)$ is

$$\begin{aligned} E\{q_0(k) q_0^T(k)\} &= \begin{bmatrix} E\{x(k)x^T(k)\} & E\{x(k)u(k)\} \\ E\{u(k)x^T(k)\} & E\{u^2(k)\} \end{bmatrix} \\ &= \begin{bmatrix} K & 0 \\ 0 & 1 \end{bmatrix} \\ &\triangleq \tilde{K}_0 \end{aligned}$$

The factored state variable equations lead to

$$q_{l+1}^{(k)} = F_{l+1} q_l^{(k)}, \quad 0 \leq l \leq L-1$$

leading to

$$\tilde{K}_{l+1} = E\left\{ q_{l+1}^{(k)} (k+1) \left(q_{l+1}^{(k)} (k+1) \right)^T \right\}$$

$$= F_{l+1} \tilde{K}_l F_{l+1}^T$$

Since the corresponding state variable description is

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} = F_L F_{L-1} \dots F_1$$

we have

$$\begin{aligned} \tilde{K}_L &= E \{ q_L(k) q_L^T(k) \} \\ &= E \left\{ \begin{bmatrix} x(k+1) \\ y(k) \end{bmatrix} \begin{bmatrix} x^T(k+1) & y(k) \end{bmatrix} \right\} \\ &= \begin{bmatrix} A & B \\ C & D \end{bmatrix} \tilde{K}_0 \begin{bmatrix} A^T & B^T \\ C^T & D^T \end{bmatrix} \\ &= \begin{bmatrix} AKA^T + BB^T & AKC^T + BD^T \\ CKA^T + DB^T & CKC^T + D^2 \end{bmatrix} \\ &= \begin{bmatrix} K & AKC^T + BD^T \\ CKA^T + DB^T & r_{yy}(0) \end{bmatrix} \end{aligned}$$

3.8 Frequency transformations and round-off noise

Section 2.3 describes frequency transformations of state-variable filters. If the prototype filter, $H(z)$ of order n , is defined by the state-variable filter $\{A, B, C, D\}$ and the all-pass frequency transformation $1/F(z)$ of order m , is defined by $\{\alpha, \beta, \gamma, \delta\}$, then the transformed filter, $G(z) = H(F(z))$, defined by $\{\mathfrak{A}, \mathfrak{B}, \mathfrak{C}, \mathfrak{D}\}$ is:

$$\begin{aligned} \mathfrak{A} &= I \otimes \alpha + A(I - \delta A)^{-1} \otimes \beta \gamma \\ \mathfrak{B} &= (I - \delta A)^{-1} B \otimes \beta \\ \mathfrak{C} &= C(I - \delta A)^{-1} \otimes \gamma \\ \mathfrak{D} &= D + \delta C(I - \delta A)^{-1} B \end{aligned}$$

Mullis and Roberts [21, Section III], consider the state and output covariance matrixes, (also called the controllability and observability Gramians) \mathfrak{K} and \mathfrak{W} of the transformed filter:

$$\begin{aligned} \mathfrak{K} &= \mathfrak{A} \mathfrak{K} \mathfrak{A}^T + \mathfrak{B} \mathfrak{B}^T \\ \mathfrak{W} &= \mathfrak{A} \mathfrak{W} \mathfrak{A}^T + \mathfrak{C}^T \mathfrak{C} \end{aligned}$$

They prove that if $1/F(z)$ is a stable m th degree all-pass filter, then there is a positive-definite $m \times m$ symmetric matrix Q for which:

$$\begin{aligned} Q &= \alpha Q \alpha^T + \beta \beta^T \\ Q^{-1} &= \alpha Q^{-1} \alpha^T + \gamma^T \gamma \end{aligned}$$

Consequently, if

$$\begin{aligned} K &= AKA^T + BB^T \\ W &= AW A^T + C^T C \end{aligned}$$

then

$$\mathfrak{K} = K \otimes Q \tag{3.3}$$

$$\mathfrak{W} = W \otimes Q^{-1} \tag{3.4}$$

and the nm second-order modes of the filter $G(z) = H(F(z))$ are m copies of the n second-order modes of $H(z)$.

Chapter 4

State variable filter realisation as a cascade of second order sections

4.1 Second Order State Variable Filters Optimised for Overflow and Round-Off Noise

Section 3.5 shows how to calculate the minimum noise state variable filter for an N -th order rational transfer function filter. The minimum noise filter has $\mathcal{O}(N^2)$ coefficients. This chapter describes the implementation of a rational filter transfer function as a cascade of optimised second order state variable sections having a total of $\mathcal{O}(N)$ coefficients^a. The cascade of second order sections can be pipelined for hardware implementation by inserting a delay between each section. Experience has shown that the filter realisation as a cascade of second order sections can successfully implement higher order filters than are possible with a single high order filter. The cascade of second order sections can be designed to have a round-off noise gain approaching the minimum possible. The round-off noise variance in the output of a cascade of second order sections includes:

- input quantisation noise filtered by the cascade transfer function
- quantisation noise at the output $y_j(k)$ of each sub-filter filtered by the remaining sub-filters
- quantisation noise at the output of the last sub-filter, in which case $\|g_m\|_2^2 = 1$.

4.2 Design equations for optimised second order state variable filters

Roberts and Mullis [129, Figure 9.14.1 with corrections] give the construction of the transformation matrix required to optimise a second order state variable filter, shown as Algorithm 4.1.

Bomar [18] gives design equations, shown in Algorithm 4.2 for a state variable second order section with scaling $\delta = 1$ and optimal noise performance. (See also *Roberts and Mullis* [129, Figure 9.12.1 with corrections]). *Bomar* assumes that transfer function of each second order section is arranged in the form:

$$H(z) = d + \frac{q_1 z^{-1} + q_2 z^{-2}}{1 + p_1 z^{-1} + p_2 z^{-2}} \quad (4.1)$$

Bomar [18] also gives design equations, shown in Algorithm 4.3, for a state variable second order section with scaling $\delta = 1$ and near optimal noise performance with one less multiplication (*Bomar* calls this a type III section). He shows experimentally for a 6th order low-pass Butterworth filter that the Type III section has a noise gain that is, as for the minimum-noise realisation, independent of the passband edge frequency.

The Octave function `pq2svcasc` converts the 2nd-order sections from the $d-p-q$ format of Equation 4.1 into 2nd-order *direct-form*, *Bomar-Type-III* or *minimum-noise* state-space sections.

Bomar [19] also describes realisation of second-order state-space sections that are “as computationally efficient as possible subject to preserving low-roundoff noise, low coefficient sensitivity and freedom from limit cycles”. In these realisations some matrix elements are replaced by single powers of 2.

^a*Roberts and Mullis* [129, Table 10.2.1] show that a block processing implementation of the original SISO state variable filter may well have fewer arithmetic operations per output than a realisation by a cascade of second order sections.

Algorithm 4.1 Construction of optimised second order state variable filters[129, Figure 9.14.1].

Given $K = \begin{bmatrix} k_{11} & k_{12} \\ k_{21} & k_{22} \end{bmatrix}$ and $W = \begin{bmatrix} w_{11} & w_{12} \\ w_{21} & w_{22} \end{bmatrix}$:

1. Transform K and W using a Cholesky transformation:

$$T_c = \begin{bmatrix} \sqrt{\frac{k_{11}k_{22}-k_{12}^2}{k_{22}}} & \frac{k_{12}}{\sqrt{k_{22}}} \\ 0 & \sqrt{k_{22}} \end{bmatrix}$$

so

$$K' = T_c^{-1} K T_c^{-T} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

and

$$W' = T_c^T W T_c = \begin{bmatrix} w'_{11} & w'_{12} \\ w'_{21} & w'_{22} \end{bmatrix}$$

2. Apply a rotation transformation to W' so that $w'_{12} = w'_{21} = 0$. The eigenvalues of KW are thus the eigenvalues of W' . Let

$$R(\theta) = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix}$$

$$\theta = \begin{cases} \frac{\pi}{4} & w'_{11} = w'_{22} \\ \frac{1}{2} \arctan \left(\frac{2w'_{12}}{w'_{11} - w'_{22}} \right) & w'_{11} \neq w'_{22} \end{cases}$$

Then

$$K'' = I$$

$$W'' = R(-\theta) W' (\theta)$$

$$= \begin{bmatrix} \mu_1^2 & 0 \\ 0 & \mu_2^2 \end{bmatrix}$$

3. Now apply a transformation:

$$\mu = \frac{\mu_2}{\mu_1}$$

$$T = \frac{\delta}{2} \begin{bmatrix} \sqrt{1+\mu} & -\sqrt{1+\mu} \\ \sqrt{1+\frac{1}{\mu}} & \sqrt{1+\frac{1}{\mu}} \end{bmatrix}$$

so that

$$K''' = \frac{1}{\delta^2} \begin{bmatrix} 1 & \frac{\mu_2-\mu_1}{\mu_2+\mu_1} \\ \frac{\mu_2-\mu_1}{\mu_2+\mu_1} & 1 \end{bmatrix}$$

$$W''' = \delta^2 \begin{bmatrix} \frac{(\mu_2+\mu_1)^2}{4} & \frac{\mu_2^2-\mu_1^2}{4} \\ \frac{\mu_2^2-\mu_1^2}{4} & \frac{(\mu_2+\mu_1)^2}{4} \end{bmatrix}$$

4. The optimising transform is $T_c R(\theta) T$.

$$b_2 = \sqrt{\frac{(1 - p_2) \left[(1 + p_2)^2 - p_1^2\right]}{(1 + p_2) \left[1 + \left(\frac{p_1}{2}\right)^2\right] - p_1^2}}$$

$$c_1 = \frac{q_2 + A_{11} q_1}{A_{12} b_2}$$

$$c_2 = \frac{q_1}{b_2}$$

4.3 Block optimal second order cascade filter realisations

A cascade of individually optimised second order sections is not block optimal. That is, with the constraint that the sectional structure is maintained, the output round off noise of the cascade will not be minimised. This is so because for a white noise input the covariance matrix of the downstream sub-filters must be calculated for a coloured rather than white noise input. A cascade realization can be block optimised by:

1. Find the state variable description $\{A, B, C, D\}$ of the cascade
2. Find the $\{K, W\}$ matrixes of the cascade. For a cascade of second order sections, the 2×2 blocks on the diagonals are the covariance and noise gain matrices of the individual sections $\{K_i, W_i\}$
3. Find the transformation, T_i , that optimises $\{K_i, W_i\}$ for each section
4. Apply these T_i to each section in the cascade

4.4 An example of a second-order state-variable cascade filter

The Octave script `svcasc2noise_example_test.m` designs a 20th order Butterworth filter with cut-off frequency $f_c = 0.1 f_S$, where f_S is the sample rate, realised as a cascade of direct-form, Bomar Type III, minimum noise or block-optimised second-order state-space sections with a state variable scaling of $\delta = 4$. The Octave function `butter2pq` calculates the coefficients of a highpass or lowpass Butterworth filter with second order sections in the form of the rational transfer function shown in Equation 4.1. The sections are ordered with increasing pole angle.^b The Octave function `pq2svcasc` converts these coefficients to second-order direct-form, Bomar Type III or minimum-noise state-space sections. The `pq2blockKWopt` function block-optimises the second-order direct-form cascade realisation. If the transfer function has odd order then `pq2blockKWopt` makes the final section a direct-form first-order section with an unused state variable. Note that, to avoid numerical problems, the `svcasc2Abcd` function will quietly remove an obviously unused state variable so that the state variable matrixes have the expected size for the odd filter order. For an odd order filter realised as a cascade of second-order minimum-noise or Bomar Type III sections `svcasc2Abcd` may not be able to remove the unused state variable. This may cause numerical problems when calculating the K and W covariance matrixes of the complete second-order cascade. In practice, the block-optimised second-order cascade, as generated by `pq2blockKWopt`, is the preferred realisation.

The example script uses the Octave function `svcasc2noise` to calculate the section noise-gain for each realisation generated by `pq2svcasc` and for the block-optimised realisation generated by `pq2blockKWopt`. `svcasc2noise` also calculates an estimate of the contribution of the output roundoff noise for that section at the overall cascade output. Finally, `svcasc2noise` estimates the optimal state variable bit distribution according to Equation 3.2.

The example script compares the overall noise gains for each cascade realisation with the section pole angles in increasing and decreasing order. That is, in the latter case the sections are in the reverse order to that calculated by `butter2pq`.

For comparison, the example script finds the overall state-space matrix with `svcasc2Abcd` and calculates the noise gain of the globally optimised filter. Recall that in the worst case, the globally optimised N th order filter requires $(N + 1)^2$ multiplies and the second-order cascade requires $4.5N$ multiplies.

Finally, the example script compares the estimated and simulated output roundoff noise variance of the block optimised second order cascade lowpass and highpass filters with the globally optimised state variable versions of those filters.

4.4.1 Comparison of calculated noise gains

Table 4.1 shows the section noise gains for each low-pass filter realisation. The coefficients used for these calculations are exact, not rounded, in order to illustrate the frequency independence of the optimised sections. As expected, the second-order minimum-noise, block-optimised and globally optimised realisations have the same noise gain in the high-pass and low-pass filters. Table 4.2 shows the section noise gains for each high-pass filter realisation.

Recall that the noise gain for each section estimates the contribution of the state variable roundoff noise from that section in the overall filter cascade output. This is *not* the same as the noise gain from the section state variables to the section output. If you calculate the latter separately for each section, then the state variable noise gain at each section output of the minimum-noise

^bThe Octave function `sos2pq` converts the output of the Octave-Forge `signal` package [104] `tf2sos` function to p - q format

filter will be found to be less than that of the corresponding section from the Bomar Type III filter. This explains the apparent discrepancies in Table 4.1 and Table 4.2. The noise-gains for each second-order minimum-noise section calculated according to Bomar's equations, as shown in Algorithm 4.2, agree with those calculated following the general method shown in Algorithm 4.1, although the state variable coefficients found by the two methods are different.

Tables 4.3 and 4.4 show the overall noise gains for each filter realisation with sections ranked in order of increasing and decreasing pole angle for the lowpass and highpass filters respectively. For the block optimised cascade the noise gain in parentheses shows that calculated if the cascade is not re-optimised after the section order is reversed.

4.4.2 Simulation results

Figure 4.1 shows the simulated response of the 20th order Butterworth lowpass filter realised as a block optimised cascade of second order sections with coefficients rounded to 10 bits and 10 bit state storage. Figure 4.2 shows the simulated response of the corresponding 20th order Butterworth highpass filter. Tables 4.5 and 4.6 show the simulated and estimated output roundoff noise variance for the 20th order Butterworth lowpass and highpass filter respectively.

The input signal is a uniformly distributed random noise signal with a nominal standard deviation of 2^8 . The state variables are scaled with $\delta = 4$ so that the nominal standard deviation of the state variables is 2^6 . In each case the section outputs, state variables and coefficients are rounded to 10 bits. The effect of coefficient truncation on the noise-gain is seen by comparison with

the calculated values shown in Table 4.3 and Table 4.4. The simulation results suggest that, to avoid overflow, the intermediate section outputs should be kept in a double-length accumulator. For comparison, the tables show the simulation results for the globally-optimised filter and the improvement obtained by adding an extra bit to the state variables in the first 6 sections of the block-optimised filter. (See Equation 3.2). When calculating the output noise gain of the block optimised cascade with additional state variable bits in some sections, the noise gain for the individual section is scaled in proportion to the number of extra bits for that section. The nominal standard deviation of these state variables is 2^7 .

4.4.3 Comparison with an N=10 example

The order 20 Butterworth filter was chosen as an extreme example. Table 4.7 shows the simulation results obtained by setting $N = 10$ in *svcasc2noise_example_test.m*.

4.5 Coefficient sensitivity and round-off noise of first-order and second-order all-pass filter sections

Digital filters implemented as the parallel combination of two or more allpass filters typically have low coefficient sensitivity [116]. The transfer function of a filter consisting of parallel all-pass filters $A(z)$ and $B(z)$ is:

$$H(z) = \frac{A(z) + B(z)}{2}$$

The frequency response of this filter is:

$$H(\omega) = \frac{e^{\phi_A(\omega)} + e^{\phi_B(\omega)}}{2}$$

where $\phi_A(\omega)$ and $\phi_B(\omega)$ are the phase responses of the all-pass filters. The corresponding squared-amplitude, phase and group delay responses are:

$$\begin{aligned} |H(\omega)|^2 &= \frac{1 + \cos(\phi_A(\omega) - \phi_B(\omega))}{2} \\ \phi_H(\omega) &= \frac{\phi_A(\omega) + \phi_B(\omega)}{2} \\ T(\omega) &= -\frac{1}{2} \left[\frac{\partial \phi_A(\omega)}{\partial \omega} + \frac{\partial \phi_B(\omega)}{\partial \omega} \right] \end{aligned}$$

When the all-pass branches of a parallel all-pass filter are realised as the cascaded connection of first and second order all-pass filters then the phase response of each branch is, without loss of generality, $\phi_A(\omega) = \sum_l \phi_{A_l}(\omega)$ where ϕ_{A_l} is the phase response of the l 'th first or second order all-pass section. If x represents a multiplier coefficient in the realisation of section A_l , then the squared-amplitude and group delay sensitivities with respect to x are:

$$\begin{aligned} S_x^{|H|^2}(\omega) &= -\frac{1}{|H(\omega)|^2} \frac{\sin(\phi_A(\omega) - \phi_B(\omega))}{2} \frac{\partial \phi_{A_l}(\omega)}{\partial x} \\ S_x^T(\omega) &= -\frac{1}{T(\omega)} \frac{1}{2} \frac{\partial^2 \phi_{A_l}(\omega)}{\partial \omega \partial x} \end{aligned}$$

The transfer function of a first order all-pass filter section is:

$$H(z) = -\frac{r - z^{-1}}{1 - rz^{-1}}$$

where r is real. The filter is stable if $|r| < 1$.

The transfer function of a second order all-pass filter section is:

$$H(z) = \frac{a_2 + a_1 z^{-1} + z^{-2}}{1 + a_1 z^{-1} + a_2 z^{-2}}$$

The transfer function of a second order all-pass filter section with complex poles in the z -plane at $z = re^{\pm i\theta}$ is:

$$\begin{aligned} H(z) &= \frac{(re^{i\theta} - z^{-1})(re^{-i\theta} - z^{-1})}{(1 - re^{i\theta}z^{-1})(1 - re^{-i\theta}z^{-1})} \\ &= \frac{r^2 - 2r \cos \theta z^{-1} + z^{-2}}{1 - 2r \cos \theta z^{-1} + r^2 z^{-2}} \end{aligned}$$

where r is real. The filter is stable if $|r| < 1$. The transfer function of a second order all-pass filter section with real poles in the z -plane at $z = r_1, r_2$ is:

$$\begin{aligned} H(z) &= \frac{(r_1 - z^{-1})(r_2 - z^{-1})}{(1 - r_1 z^{-1})(1 - r_2 z^{-1})} \\ &= \frac{r_1 r_2 - (r_1 + r_2) z^{-1} + z^{-2}}{1 - (r_1 + r_2) z^{-1} + r_1 r_2 z^{-2}} \end{aligned}$$

The filter is stable if $|r_1| < 1$ and $|r_2| < 1$.

This section surveys the maximum phase response gradient, $\frac{\partial \phi}{\partial x}$, and round-off noise performance of a selection of first-order and second-order all-pass filter section transfer functions and realisations. The Maxima script *allpass_filter.max* performs the algebra required to find the state variable description of each realisation and the Octave scripts *Abcd2H.m* and *H2P.m* calculate the phase response gradient (see Appendix H).

4.5.1 Searching for realisations of all-pass filter transfer functions

Mitra and Hirano [142] show a catalogue of realizations of minimum multiplier first and second order all-pass filters. They consider realizations of the *Type 1* first order all-pass transfer function:

$$H_1(z) = \frac{z^{-1} - b_1}{1 - b_1 z^{-1}} \quad (4.2)$$

as a *two-port* network with a constraint:

$$\begin{bmatrix} Y_1 \\ Y_2 \end{bmatrix} = \begin{bmatrix} t_{11} & t_{12} \\ t_{21} & t_{22} \end{bmatrix} \begin{bmatrix} X_1 \\ X_2 \end{bmatrix}$$

$$X_2 = b_1 Y_2$$

Eliminating variables X_2 and Y_2 :

$$\frac{Y_1}{X_1} = \frac{t_{11} - b_1(t_{11}t_{22} - t_{12}t_{21})}{1 - t_{22}b_1}$$

Comparing with Equation 4.2:

$$\begin{aligned} t_{11} &= t_{22} = z^{-1} \\ t_{12}t_{21} &= z^{-2} - 1 \end{aligned}$$

There are four possible realisations of t_{12} and t_{21} : $t_{12} = z^{-2} - 1$, $t_{21} = 1$ and $t_{12} = z^{-1} - 1$, $t_{21} = z^{-1} + 1$ and their transposed equivalents [142, Fig. 2].

In a similar fashion, *Mitra and Hirano* find realisations of the *Type 2* and *Type 3* second order all-pass transfer functions:

$$H_{MH2}(z) = \frac{z^{-2} - b_1 z^{-1} + b_1 b_2}{1 - b_1 z^{-1} + b_1 b_2 z^{-2}} \quad (4.3a)$$

$$H_{MH3}(z) = \frac{z^{-2} - b_1 z^{-1} + b_2}{1 - b_1 z^{-1} + b_2 z^{-2}} \quad (4.3b)$$

Their realisations of these transfer functions are constrained to have only 2 multipliers but may have more than 2 delays. *Mitra and Hirano* show 4 Type 2 and 8 Type 3 realisations^c. *Mitra and Hirano* show plots of the estimated output round-off noise of each realisation [142, Fig.9, Fig.10 and Fig.11] due to truncation at the multiplier outputs. This estimate does not include the round-off noise due to truncation at the register inputs.

Nishihara and Sugahara [7] present a catalogue of general (not just all-pass) second order filter realisations with low pole sensitivity with respect to each of the two multipliers in the realisation. They show 37 realisations^d.

Szczupak et. al [65] describe a computer based search for realisations in which the two coefficients of the second order all-pass filter transfer function are themselves functions of two multipliers. They find 646 distinct realisations.

4.5.2 Maximum phase gradient and round-off noise of some first-order all-pass filter sections

Equation 4.4 is the transfer function of the first order direct form all-pass filter section shown in Figure 4.3a. This realisation has 2 multipliers.

$$H_{Dir1}(z) = \frac{b_1 + z^{-1}}{1 + b_1 z^{-1}} \quad (4.4)$$

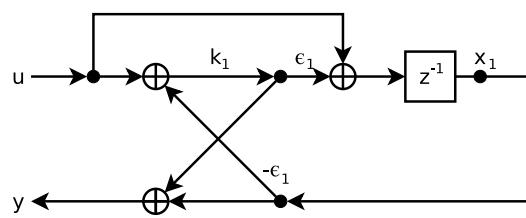

The *Gray and Markel* [4] first order all-pass filter section shown in Figure 4.3b also implements the transfer function of Equation 4.4. The $\epsilon_1 = \pm 1$ are chosen to scale the state for good numerical performance in the implementation. The choice of ϵ does not alter the transfer function or the noise gain.

Equation 4.5 is the transfer function of the first order all-pass filter section of *Stoyanov et al.* [45] shown in Figure 4.3c. This realisation has low sensitivity for filter poles near $z = 1$.

$$H_{LS1}(z) = \frac{-(1 - c_1) + z^{-1}}{1 - (1 - c_1) z^{-1}} \quad (4.5)$$

(a) Direct form first order all-pass filter section

(b) Gray and Markel first order all-pass filter section

(c) Stoyanov et al. low sensitivity first order all-pass filter section

Figure 4.3: First order all-pass filter sections

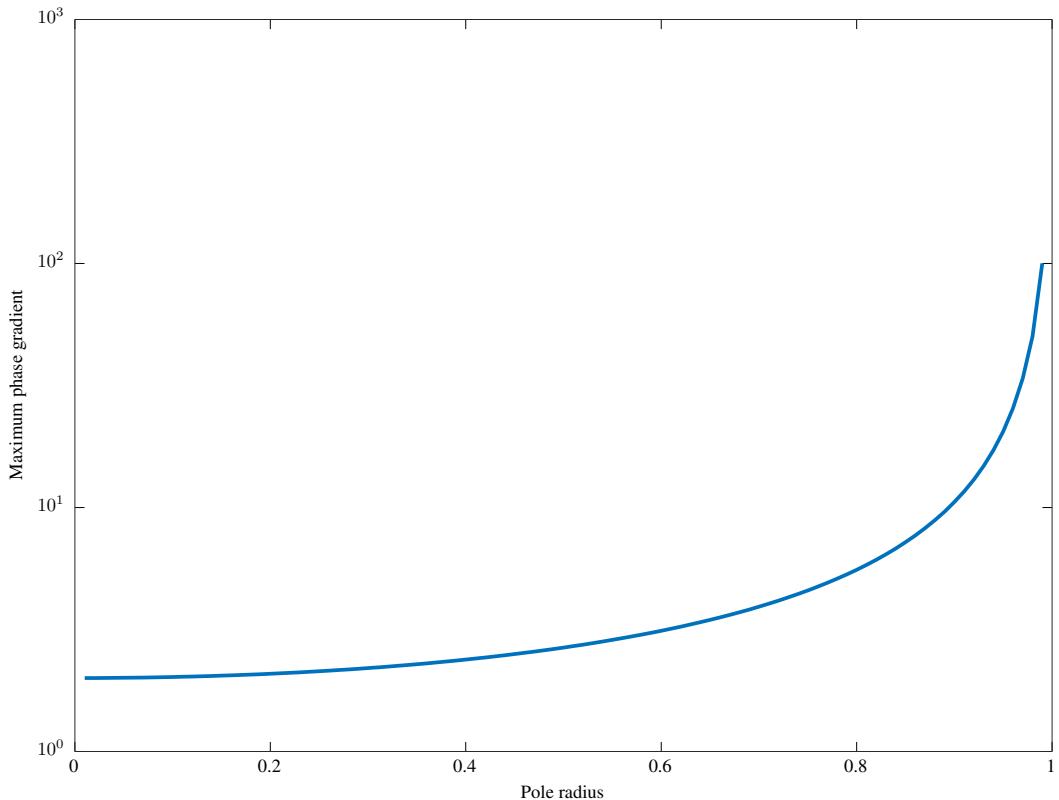

Figure 4.4: Maximum phase gradient plotted against pole radius of first order all-pass filter sections

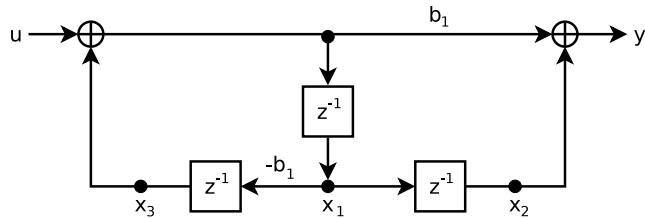

Figure 4.5: Retimed first-order direct form all-pass filter section

Figure 4.4 plots the maximum of the gradient of the first-order all-pass filter phase response with respect to the section coefficient against the pole radius. It is the same for each realisation. The noise gain of each scaled realisation was calculated with the Octave function *Abcd2ng.m*, as shown in Chapter 3. The noise gain is found to be 1 for each realisation regardless of pole radius. For the direct-form section, a *slowed* and *retimed* realisation, shown in Figure 4.5, was analysed. *Slowing* is the replacement of each z^{-1} delay by z^{-M} , reducing the sample rate. The realisation is *retimed* by distributing the delays so that there is a register, or state, at each multiplier output. This allows calculation by the state-variable method of the output round-off noise due to truncation at both the register inputs and the multiplier outputs. See *Parhi* [73, Chapter 4] for a description of retiming algorithms. The Maxima script *allpass_filter_retimed.max* performs the algebra required to find the state variable description of each retimed filter realisation.

4.5.3 Maximum phase gradient and round-off noise of some second-order all-pass filter sections

Equation 4.6 is the transfer function of the second-order direct-form all-pass filter section shown in Figure 4.6a. This realisation has 4 multipliers.

$$H_{Dir2}(z) = \frac{b_2 + b_1 z^{-1} + z^{-2}}{1 + b_1 z^{-1} + b_2 z^{-2}} \quad (4.6)$$

Equation 4.7 is the transfer function of the second order Gray-and-Markel all-pass filter section shown in Figure 4.6b. The

^cThere are equal numbers of transposed realisations.

^dNote the complexity of the classification map shown in Figure 2!

$\epsilon_1, \epsilon_2 = \pm 1$ are chosen to scale the states.

$$H_{GM2}(z) = \frac{k_2 + k_1(1+k_2)z^{-1} + z^{-2}}{1 + k_1(1+k_2)z^{-1} + k_2z^{-2}} \quad (4.7)$$

Figure 4.6c shows a realisation of Equation 4.7 due to *Ansari* and *Lui* [130]. This realisation has low noise gain for poles near $z = \pm i$.

The three port transfer matrix of the *Mitra* and *Hirano* [142] type 2d realisation of Equation 4.3a is:

$$\begin{bmatrix} z^{-2} & 1 & 0 \\ z^{-1}(z^{-2}-1) & z^{-1} & 1 \\ z^{-4}-1 & z^{-2} & 0 \end{bmatrix} \quad (4.8)$$

and that of the type 3d realisation of Equation 4.3b is:

$$\begin{bmatrix} z^{-2} & 1 & 1 \\ z^{-1}(z^{-2}-1) & z^{-1} & z^{-1} \\ z^{-4}-1 & z^{-2} & z^{-2} \end{bmatrix} \quad (4.9)$$

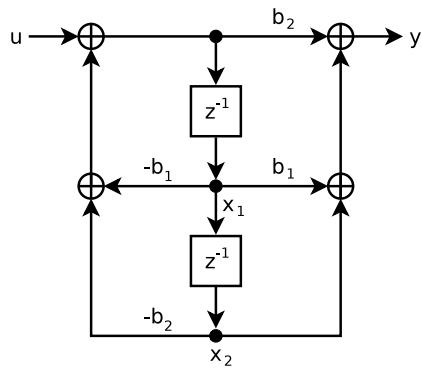

Figures 4.6d and 4.6e show the type 2d and transposed type 2d realisations of Equation 4.3a. Figures 4.6f and 4.6g show the type 3d and transposed type 3d realisations of Equation 4.3b. The state variable implementations of the transposed realisations have duplicated state updates. In other words, the rows of the state-transition matrix are not linearly independent.

Equation 4.10 is the transfer function of the second order all-pass filter section of *Stoyanov et al.* [45] shown in Figure 4.6h. This realisation has low sensitivity for filter poles near $z = 1$.

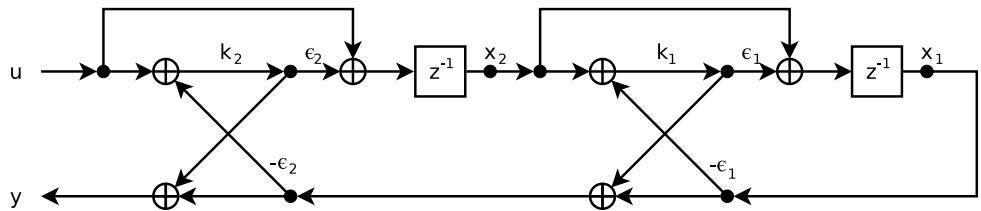

$$H_{LS2}(z) = \frac{(1-c_2) + (2c_1+c_2-2)z^{-1} + z^2}{1 + (2c_1+c_2-2)z^{-1} + (1-c_2)z^{-2}} \quad (4.10)$$

Equation 4.11 is the transfer function of the second order all-pass filter section of *Ivanova and Stoyanov* [70] shown in Figure 4.6i. This realisation has low sensitivity for filter poles near $z = 0$.

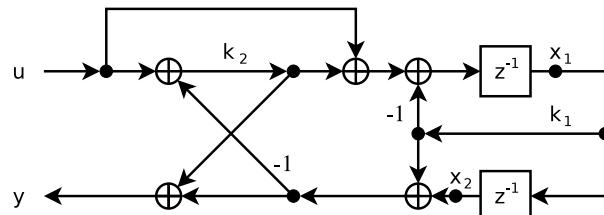

$$H_{IS}(z) = \frac{d_2 + (d_1d_2 - d_1 - 2d_2)z^{-1} + z^2}{1 + (d_1d_2 - d_1 - 2d_2)z^{-1} + d_2z^{-2}} \quad (4.11)$$

Maximum phase gradient of some second-order all-pass filter sections

Figure 4.7 shows the maximum of the gradient of the phase with respect to the second-order direct-form coefficients b_1 and b_2 in Equation 4.6 for real poles plotted against the real pole radius. Figure 4.8 shows the maximum of the gradient of the phase with respect to the same coefficients for complex conjugate poles plotted against pole angle.

Figure 4.9 shows the maximum of the gradient of the phase with respect to the second-order *Gray and Markel* and *Ansari and Lui* coefficients k_1 and k_2 in Equation 4.7 for real poles plotted against pole radius. Figure 4.10 shows the maximum of the gradient of the phase with respect to the same coefficients for complex conjugate poles plotted against pole angle.

Figure 4.11 shows the maximum of the gradient of the phase with respect to the *Mitra and Hirano* type 2d second-order all-pass filter section coefficients b_1 and b_2 in Equation 4.3a for real poles. Figure 4.12 shows the maximum of the gradient of the phase with respect to the same coefficients for complex conjugate poles. The phase gradient is not defined at a pole angle of $\frac{\pi}{2}$.

Figure 4.13 shows the maximum of the gradient of the phase with respect to the *Mitra and Hirano* type 3d second-order all-pass filter section coefficients b_1 and b_2 in Equation 4.3b for real poles. Figure 4.14 shows the maximum of the gradient of the phase with respect to the same coefficients for complex conjugate poles.

Figure 4.15 shows the maximum of the gradient of the phase with respect to the coefficients c_1 and c_2 of the second-order low-sensitivity near $z = 1$ section of *Stoyanov et al.* having the transfer function shown in Equation 4.10 for real poles. Figure 4.16 shows the maximum of the gradient of the phase with respect to the same coefficients for complex conjugate poles.

Figure 4.17 shows the maximum of the gradient of the phase with respect to the coefficients d_1 and d_2 of the second-order low-sensitivity near $z = 0$ section of *Ivanova and Stoyanov* having the transfer function shown in Equation 4.11 for real poles. Figure 4.18 shows the maximum of the gradient of the phase with respect to the same coefficients for complex conjugate poles.

Noise gain of some second-order all-pass filter sections

As for the first-order direct-form section the noise gain of the scaled second-order direct-form section can be estimated with a slowed and retimed realisation. Figure 4.19 shows the noise gain of a scaled realisation with real poles of Equation 4.6. Figure 4.20 shows the noise gain of a scaled realisation with complex conjugate poles.

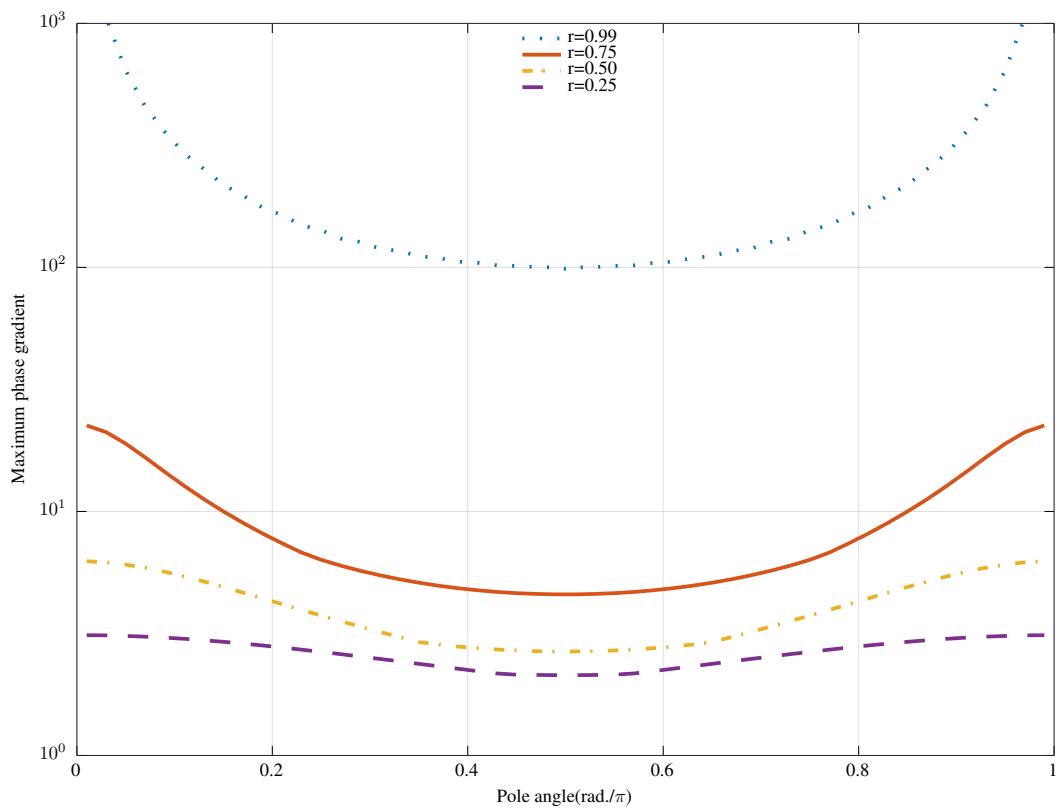

Figure 4.8: Maximum phase gradient with respect to pole angle of the second-order direct-form all-pass filter section with complex conjugate poles

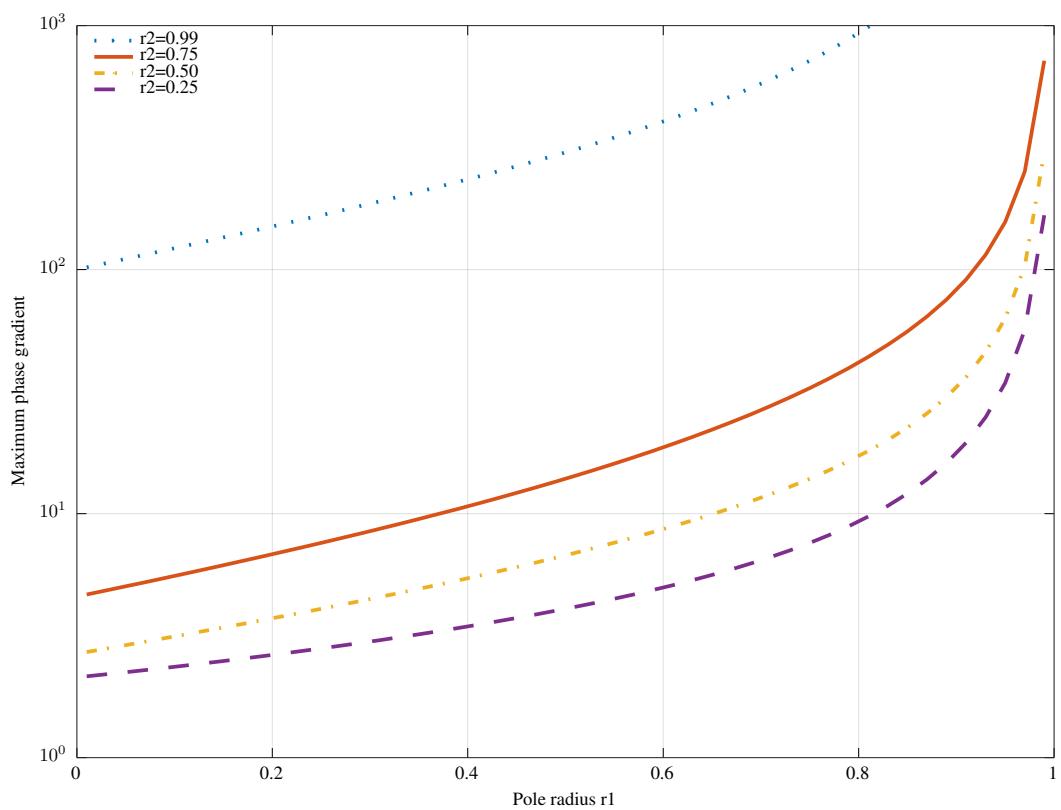

Figure 4.9: Maximum phase gradient plotted against pole radius of the second-order Gray-and-Markel and Ansari-and-Lui all-pass filter section with real poles

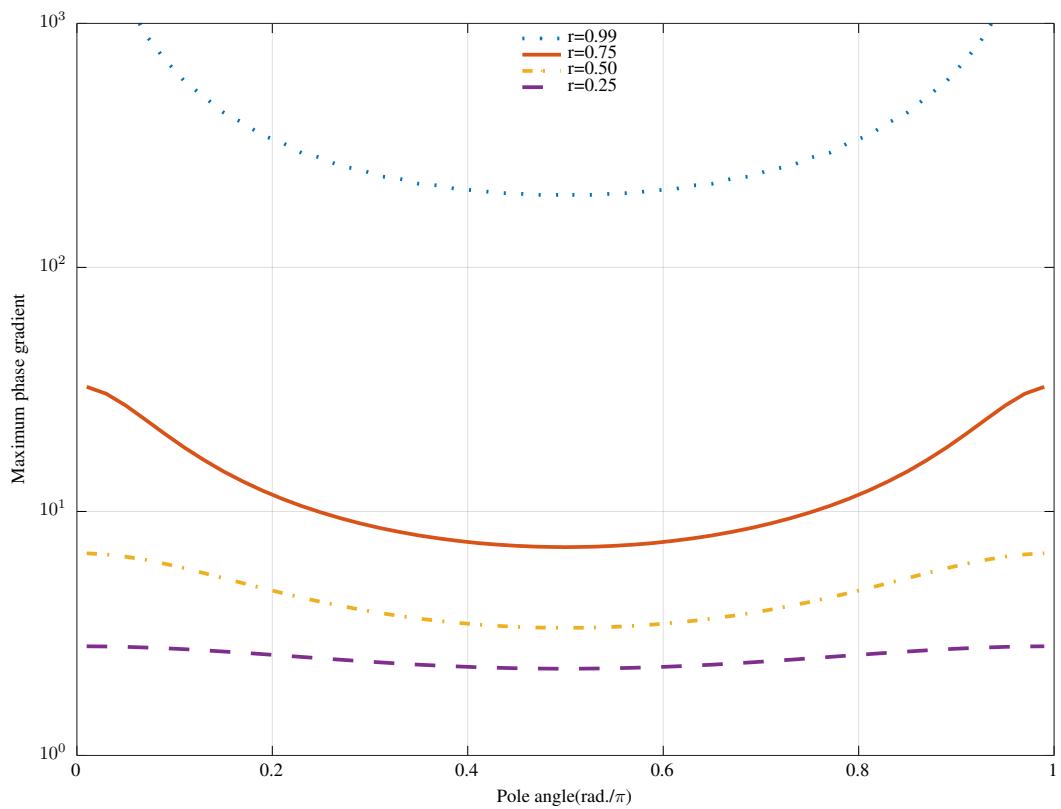

Figure 4.10: Maximum phase gradient plotted against pole angle of the second-order Gray-and-Markel and Ansari-and-Lui all-pass filter section with complex conjugate poles

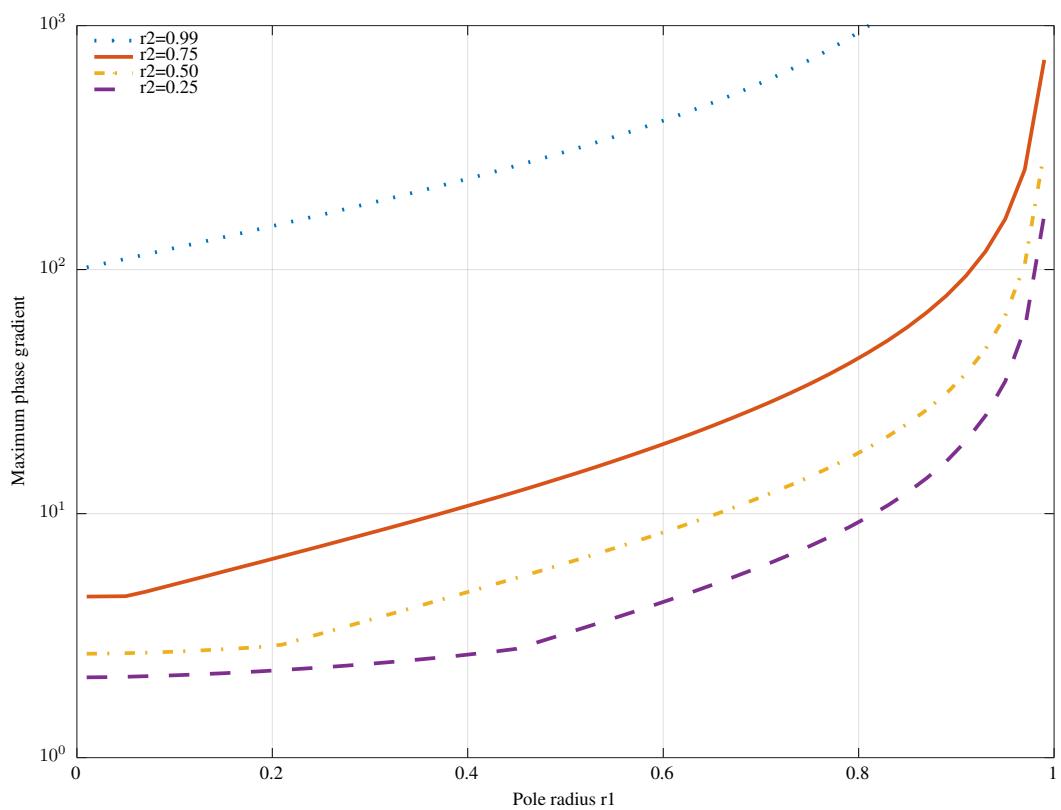

Figure 4.11: Maximum phase gradient plotted against pole radius of the second-order Mitra-and-Hirano type 2d all-pass filter section with real poles

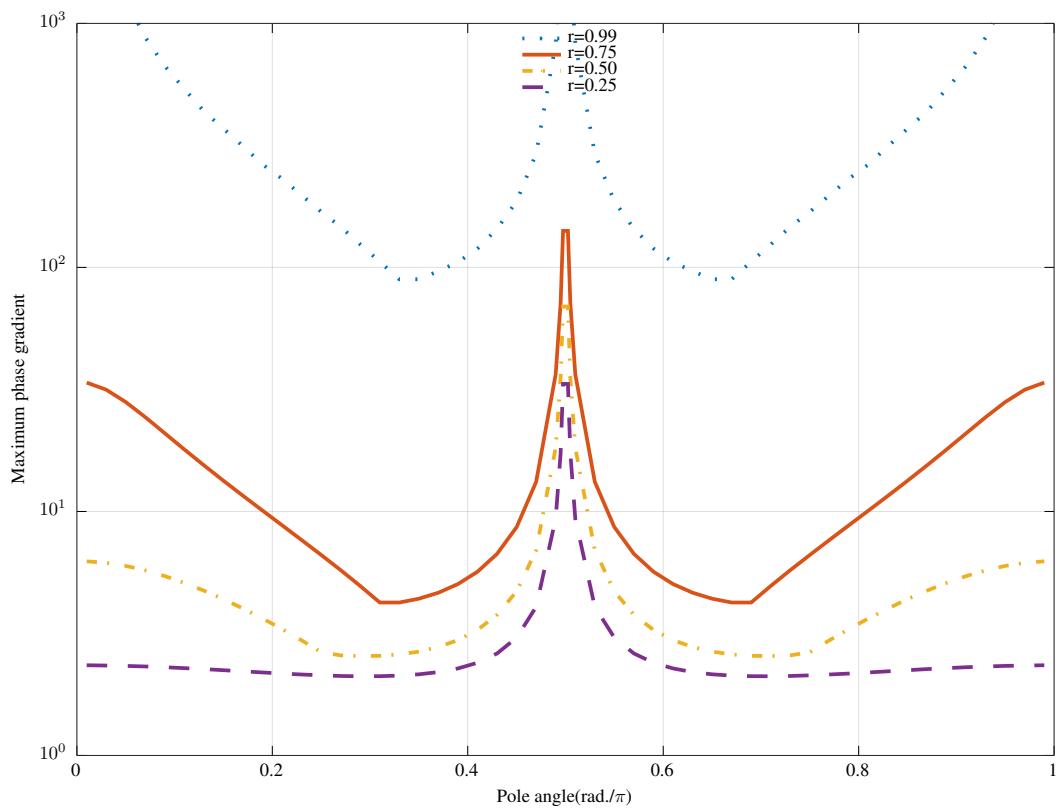

Figure 4.12: Maximum phase gradient plotted against pole angle of the second-order Mitra-and-Hirano type 2d all-pass filter section with complex conjugate poles

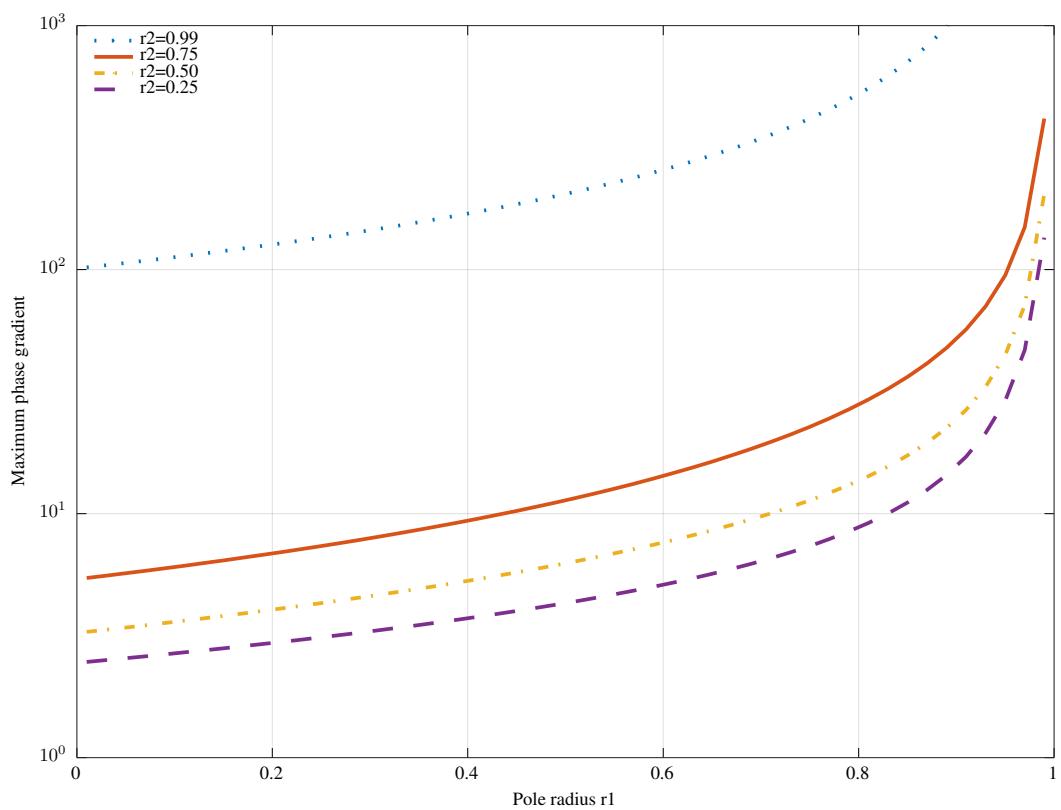

Figure 4.13: Maximum phase gradient plotted against pole radius of the second-order Mitra-and-Hirano type 3d all-pass filter section with real poles

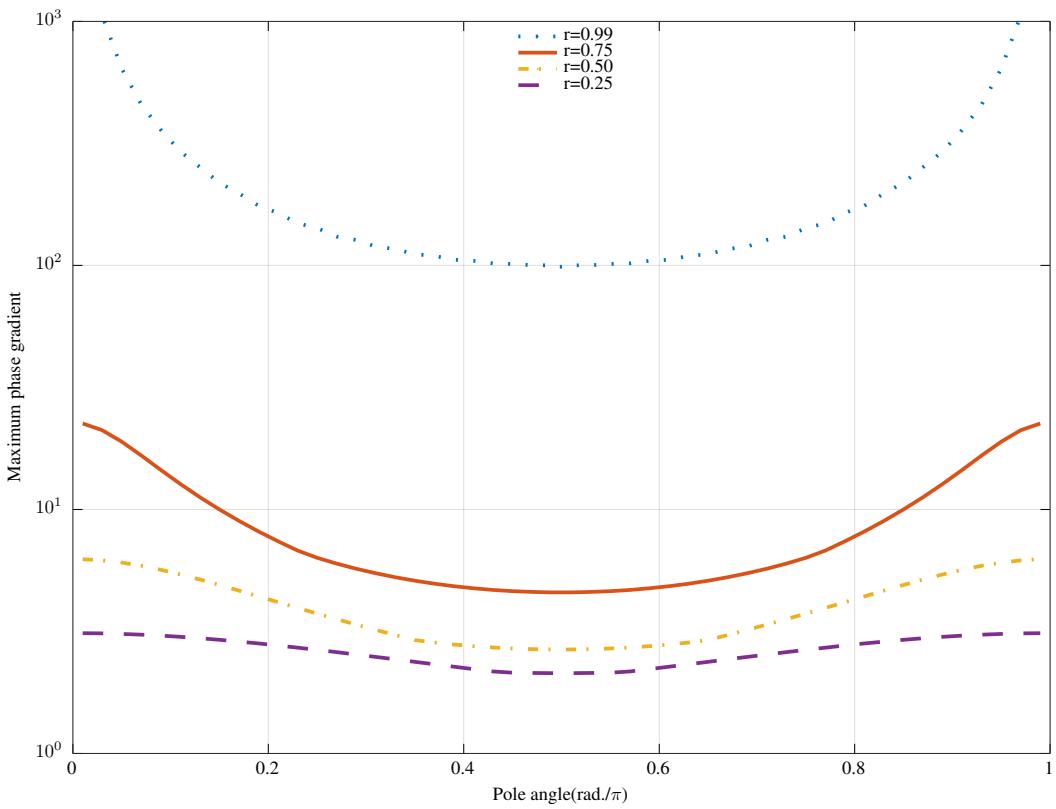

Figure 4.14: Maximum phase gradient plotted against pole angle of the second-order Mitra-and-Hirano type 3d all-pass filter section with complex conjugate poles

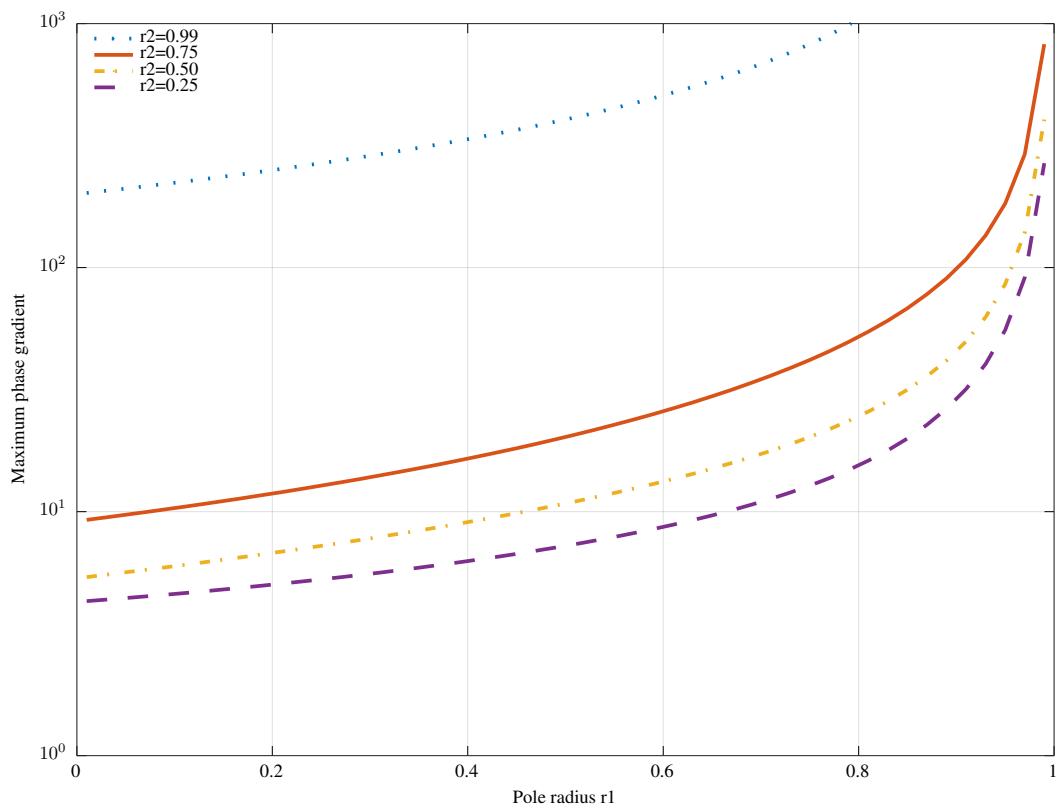

Figure 4.15: Maximum phase gradient plotted against pole radius of the second-order Stoyanov low-sensitivity near $z = 1$ all-pass filter section with real poles

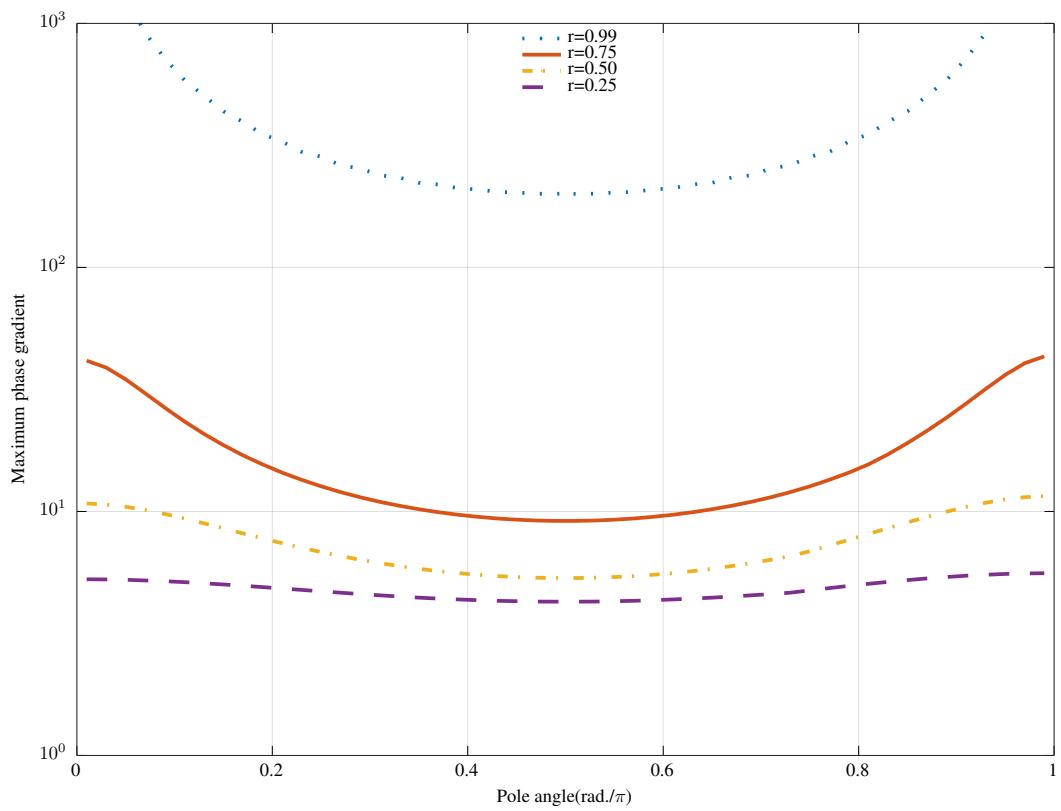

Figure 4.16: Maximum phase gradient plotted against pole angle of the second-order Stoyanov low-sensitivity near $z = 1$ all-pass filter section with complex conjugate poles

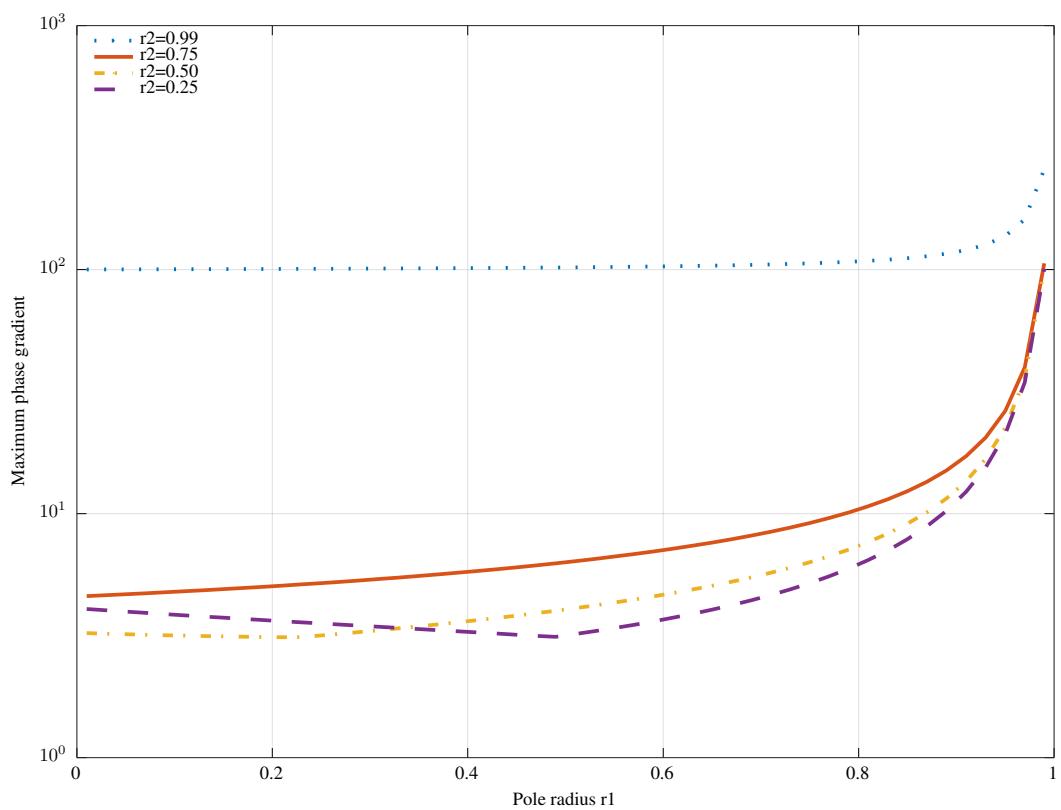

Figure 4.17: Maximum phase gradient plotted against pole radius of the second-order Ivanova and Stoyanov low-sensitivity near $z = 0$ all-pass filter section with real poles

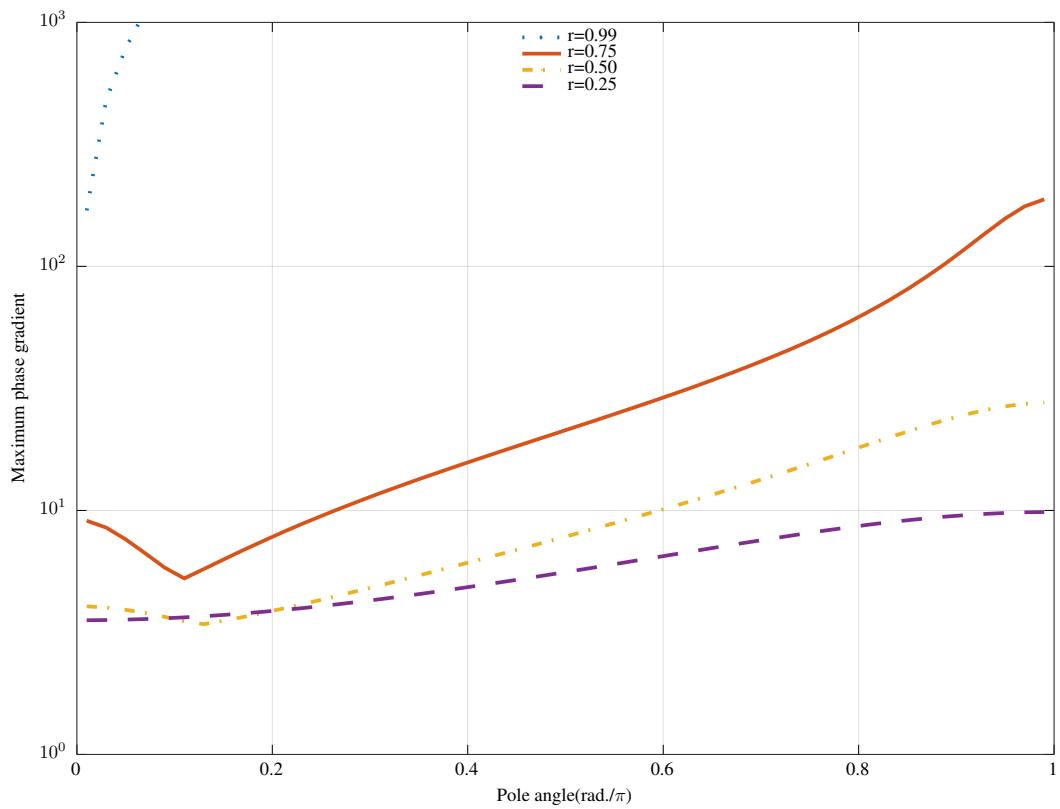

Figure 4.18: Maximum phase gradient plotted against pole angle of the second-order Ivanova and Stoyanov low-sensitivity near $z = 0$ all-pass filter section with complex conjugate poles

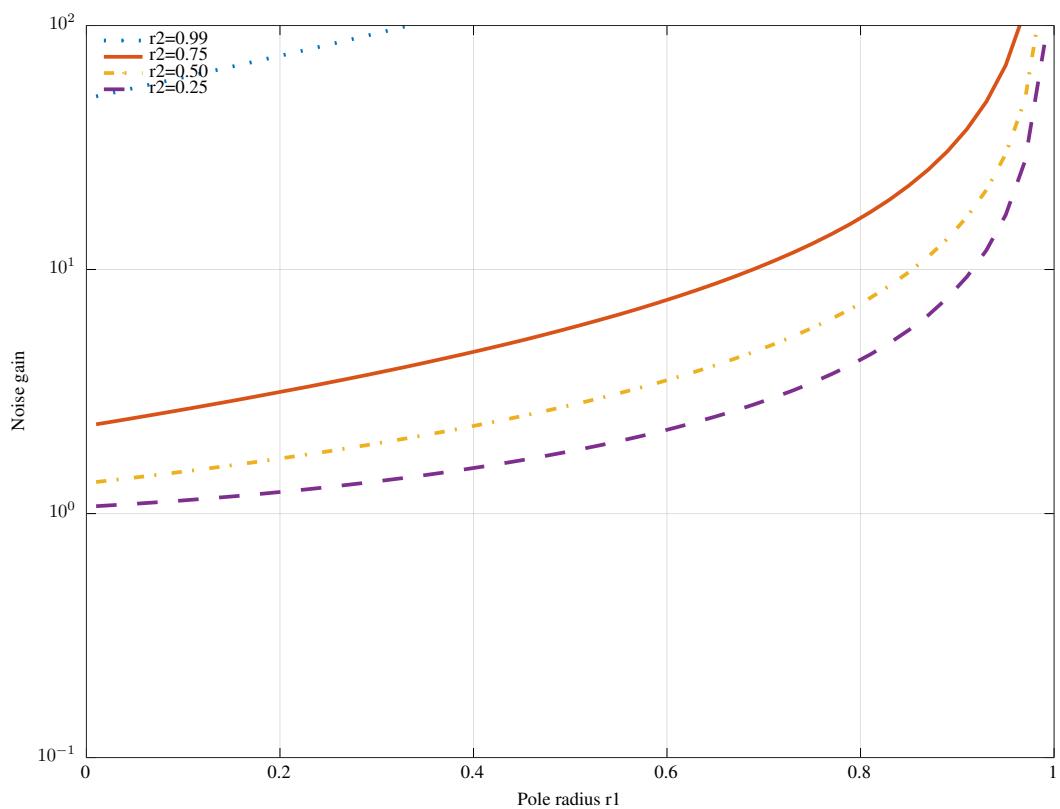

Figure 4.19: Noise gain of the scaled and retimed second-order direct-form all-pass filter section with real poles

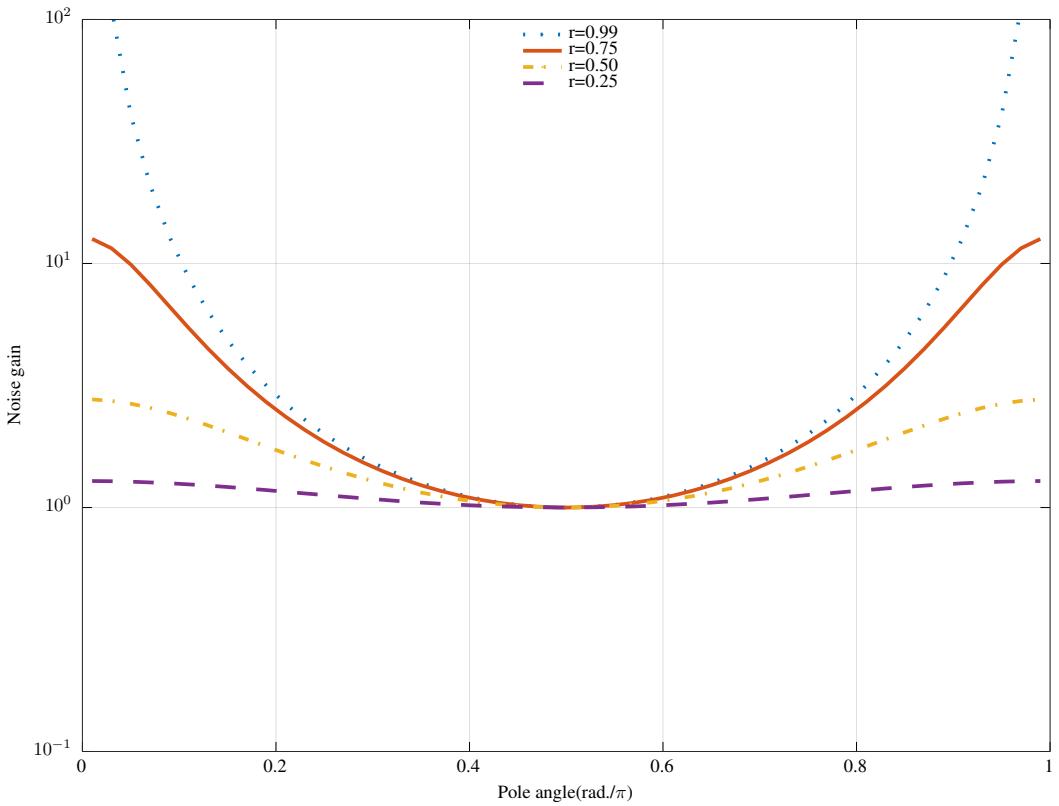

Figure 4.20: Noise gain of the scaled and retimed second-order direct-form all-pass filter section with complex conjugate poles

As for the second-order direct-form section the noise gain of the scaled second-order *Gray* and *Markel* section can be estimated with a slowed and retimed realisation. As for the first-order *Gray* and *Markel* section, the ϵ coefficients do not alter the transfer function or noise gain but must be selected for effective internal state scaling in a fixed-point implementation. Figure 4.21 shows the noise gain of a scaled realisation with real poles. Figure 4.22 shows the noise gain of a scaled realisation with complex conjugate poles.

The noise gain of the scaled second-order *Ansari* and *Lui* section can be estimated with a slowed and retimed realisation. Figure 4.23 shows the noise gain of a scaled realisation with real poles. Figure 4.24 shows the noise gain of a scaled realisation with complex conjugate poles.

The noise gain of the scaled second-order *Mitra* and *Hirano* type 2d section can be estimated with the retimed realisation shown in Figure 4.25. The section is retimed by adding a z^{-1} delay at the output and then redistributing the delay “backwards” until the output of the b_1 multiplier is registered. Figure 4.26 shows the noise gain of a scaled realisation with real poles. Figure 4.27 shows the noise gain of a scaled realisation with complex conjugate poles.

The noise gain of the scaled second-order *Mitra* and *Hirano* type 3d section can be estimated without slowing or retiming the realisation. Figure 4.28 shows the noise gain of a scaled realisation with real poles. Figure 4.29 shows the noise gain of a scaled realisation with complex conjugate poles.

The round-off noise of the second-order Stoyanov low-sensitivity section can be estimated without slowing and retiming the realisation. Figure 4.30 shows the noise gain of a scaled realisation with real poles. Figure 4.31 shows the noise gain of a scaled realisation with complex conjugate poles.

The round-off noise of the second-order *Ivanova* and *Stoyanov* low-sensitivity near $z = 0$ section can be estimated with a slowed and retimed realisation. Figure 4.32 shows the noise gain of a scaled realisation with real poles. Figure 4.33 shows the noise gain of a scaled realisation with complex conjugate poles.

Chapter 5

Filter synthesis by the Schur decomposition

This chapter follows *Parhi* [73, Chapter 12].

5.1 The Schur algorithm

From *Parhi* [73, Chapter 12]:

The Schur algorithm was originally used to test if a power series is analytic and bounded in the unit disk. If an N -th order polynomial $\Phi_N(z)$ has all zeros inside the unit circle then $N + 1$ polynomials

$$\{\Phi_i(z), i = N, N - 1, \dots, 0\}$$

can be generated by the Schur algorithm. One of the most important properties of the Schur algorithm is that these $N + 1$ polynomials form an orthonormal basis that can be used to expand any N -th order polynomial.

In this section, the inner product formulation used to demonstrate orthonormality is based on the calculation of the signal power at an internal node of a digital filter. Appendix A.6 contains a review of the complex variables theory required in this section.

5.1.1 Computation of Schur polynomials

The denominator of a stable IIR filter is a Schur polynomial because it has no zeros on or outside the unit circle. Define the N -th order denominator polynomial as:

$$D_N(z) = \sum_{i=0}^N d_i z^i$$

Initialise the N -th order Schur polynomial $\Phi_N(z)$ as:

$$\Phi_N(z) = D_N(z) = \sum_{i=0}^N \phi_i z^i$$

From $\Phi_N(z)$ form the polynomial $\Phi_{N-1}(z)$ by:

$$\begin{aligned}\Phi_{N-1}(z) &= \frac{z^{-1} \{\phi_N \Phi_N(z) - \phi_0 \Phi_N^*(z)\}}{\sqrt{\phi_N^2 - \phi_0^2}} \\ &= \frac{z^{-1} \{\Phi_N(z) - k_N \Phi_N^*(z)\}}{\sqrt{1 - k_N^2}}\end{aligned}$$

where $k_N = \phi_0/\phi_N$ and $\Phi_N^*(z)$ is the reverse polynomial of $\Phi_N(z)$ defined by:

$$\Phi_N^*(z) = z^N \Phi_N(z^{-1})$$

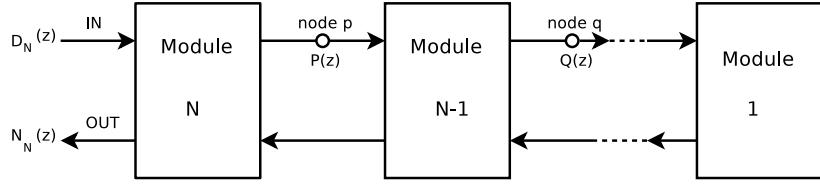

Figure 5.1: A filter structure implementing $H(z) = \frac{N_N(z)}{D_N(z)}$ (after Parhi [73, Fig. 12.1])

The degree of $\Phi_{N-1}(z)$ is 1 less than that of $\Phi_N(z)$ since, by a change of variables the numerator is:

$$\begin{aligned} z^{-1} \{ \phi_N \Phi_N(z) - \phi_0 \Phi_N^*(z) \} &= z^{-1} \sum_{i=0}^N \{ \phi_N \phi_i z^i - \phi_0 \phi_{N-i} z^i \} \\ &= \sum_{i=1}^N \{ \phi_N \phi_i - \phi_0 \phi_{N-i} \} z^{i-1} \end{aligned}$$

For $\Phi_N(z)$ to be a Schur polynomial, $|k_i| < 1$ for each polynomial in the set $\{\Phi_N(z), \Phi_{N-1}(z), \dots, \Phi_1(z)\}$. Parhi [73, Equation 12.6] points out that by inspection of $\Phi_{N-1}(z)$, the coefficients of increasing powers of z in $\Phi_{N-1}(z)$ are $\frac{1}{\sqrt{\phi_N^2 - \phi_0^2}}$ times the N determinants of the 2×2 submatrices formed by the first column and each succeeding column in the matrix:

$$\left[\begin{array}{ccccccc} \phi_N & \phi_{N-1} & \phi_{N-2} & \dots & \phi_2 & \phi_1 & \phi_0 \\ \phi_0 & \phi_1 & \phi_2 & \dots & \phi_{N-2} & \phi_{N-1} & \phi_N \end{array} \right]$$

The Schur decomposition of a polynomial is implemented in the Octave function *schurdecomp*. The C++ file *schurdecomp.cc* implements *schurdecomp* as an *oct*-file using the *MPFR* arbitrary precision floating point library [75, 126] written by Fousse et al. [1]. The mantissa precision is set to 256 bits.

5.1.2 Orthonormality of Schur Polynomials

The filter structure shown in Figure 5.1 implements a real causal stable transfer function $H(z) = N_N(z)/D_N(z)$. The transfer function from the input node to node p is $P(z)/D_N(z)$. If the input signal is modeled as random and white with unit power, then the average power at node p is:

$$\begin{aligned} P_p &= \frac{1}{2\pi} \int_{-\pi}^{\pi} \left| \frac{P(e^{i\omega})}{D_N(e^{i\omega})} \right|^2 d\omega \\ &= \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{P(e^{i\omega}) P(e^{-i\omega})}{D_N(e^{i\omega}) D_N(e^{-i\omega})} d\omega \end{aligned}$$

On the unit circle, $z = e^{i\omega}$, so in the z-domain:

$$P_p = \frac{1}{2\pi i} \oint_C \frac{P(z) P(z^{-1}) z^{-1}}{D_N(z) D_N(z^{-1})} dz$$

Where the contour is taken in the anti-clockwise direction about the origin. Recall that all the zeros of $D_N(z)$ are inside the unit circle, C . Now define the inner product of two internal polynomials $P(z)$ and $Q(z)$ as:

$$\langle P(z), Q(z) \rangle = \frac{1}{2\pi i} \oint_C \frac{P(z) Q(z^{-1}) z^{-1}}{D_N(z) D_N(z^{-1})} dz$$

so that $P_p = \langle P(z), P(z) \rangle$. This is a valid inner product definition because it has the following three properties:

1. Conjugate symmetry:

$$\langle P(z), Q(z) \rangle = \langle Q(z), P(z) \rangle^\dagger$$

where (\dagger) represents the complex conjugate transpose. This can be verified by a change of variables. The coefficients of $P(z)$ and $Q(z)$ are usually real.

2. Linearity: for any real constants α, β and γ :

$$\langle \alpha P(z), \beta Q(z) + \gamma R(z) \rangle = \alpha\beta \langle P(z), Q(z) \rangle + \alpha\gamma \langle P(z), R(z) \rangle$$

3. Positive norm:

$$\langle P(z), Q(z) \rangle \geq 0$$

with equality if and only if $P(z) = 0$.

Some identities:

$$\langle \Phi_N(z), z^i \rangle = \begin{cases} \frac{1}{\phi_N} & i = N \\ 0 & 0 \leq i \leq N-1 \end{cases}$$

PROOF: Recall that $\Phi_N^*(z) = z^N \Phi_N(z^{-1})$. Then

$$\begin{aligned} \langle \Phi_N(z), z^i \rangle &= \frac{1}{2\pi i} \oint_C \frac{\Phi_N(z) z^{-i}}{\Phi_N(z) \Phi_N(z^{-1})} dz \\ &= \frac{1}{2\pi i} \oint_C \frac{z^{N-i-1}}{\Phi_N^*(z)} dz \\ &= \begin{cases} \frac{1}{\phi_N} & i = N \\ 0 & otherwise \end{cases} \end{aligned}$$

The reverse Schur polynomial has all its roots outside the unit circle so the integrand is analytic within the unit circle if $0 \leq i < N$ and Cauchy's Integral Theorem applies. The result for $i = N$ follows from Cauchy's Integral Formula. Similarly:

$$\langle \Phi_N^*(z), z^i \rangle = \begin{cases} \frac{1}{\phi_N} & i = 0 \\ 0 & i \geq 1 \end{cases}$$

If

$$P(z) = \sum_{i=0}^N p_i z^i$$

then:

$$\begin{aligned} \langle \Phi_N(z), P(z) \rangle &= \frac{p_N}{\phi_N} \\ \langle \Phi_N^*(z), P(z) \rangle &= \frac{p_0}{\phi_N} \end{aligned}$$

Also:

$$\begin{aligned} \langle \Phi_N(z), \Phi_N(z) \rangle &= 1 \\ \langle \Phi_N^*(z), \Phi_N^*(z) \rangle &= 1 \\ \langle \Phi_N(z), \Phi_N^*(z) \rangle &= \frac{\phi_0}{\phi_N} \\ \langle z^{-j} \Phi_N(z), z^i \rangle &= \langle \Phi_N(z), z^{i+j} \rangle \\ \langle z^{-j} \Phi_N^*(z), z^i \rangle &= \langle \Phi_N^*(z), z^{i+j} \rangle \end{aligned}$$

The Schur polynomials satisfy the following orthonormality condition:

$$\langle \Phi_i(z), \Phi_j(z) \rangle = \begin{cases} 1 & i = j \\ 0 & i \neq j \end{cases}$$

where $0 \leq i, j \leq N$. See the proof in *Parhi* [73, Appendix D]. The reverse Schur polynomials are not orthonormal. However:

$$\begin{aligned} \langle \Phi_i^*(z), z^{i-j} \Phi_j^*(z) \rangle &= \langle z^{j-i} \Phi_j^*(z^{-1}), \Phi_i^*(z^{-1}) \rangle \\ &= \langle z^j \Phi_j^*(z^{-1}), z^i \Phi_i^*(z^{-1}) \rangle \\ &= \langle \Phi_j(z), \Phi_i(z) \rangle \\ &= 0 \end{aligned}$$

where $0 \leq j \leq i \leq N$. Therefore the polynomials

$$\{\Phi_N^*(z), z \Phi_{N-1}^*(z), z^2 \Phi_{N-2}^*(z), \dots, z^N \Phi_0^*(z)\}$$

also form an orthonormal basis. This basis can be used to synthesise an alternative lattice structure. *Parhi* [73, Section 12.7.2] shows that the reverse polynomial structure has inferior round off noise performance when compared with the forward polynomial structure described later in this summary.

5.1.3 Polynomial Expansion Algorithm

The Schur polynomials in the set $\{\Phi_N(z), \dots, \Phi_0(z)\}$ form an orthonormal basis. Therefore any N -th order polynomial $N_N(z)$ can be expanded as

$$N_N(z) = \sum_{i=0}^N c_i \Phi_i(z)$$

Algorithm 5.1 shows the Schur expansion of an arbitrary polynomial in a Schur basis.

Algorithm 5.1 Schur polynomial expansion (see *Parhi* [73, Section 12.2.3])

For any polynomial $N_m(z)$ of degree m , ($0 < m \leq N$):

```

 $Q(z) = N_m(z)$ 
 $c_i = 0$ , for  $m < i \leq N$ 
for  $i = m, m - 1, \dots, 0$  do
   $c_i = \frac{Q^*(0)}{\Phi_i^*(0)}$ 
   $Q(z) = Q(z) - c_i \Phi_i(z)$ 
end for
```

$Q^*(z)$ and $\Phi_i^*(z)$ are the reverse polynomials of $Q(z)$ and $\Phi_i(z)$.

For lattice filter implementations of a rational transfer function, the denominator is synthesised using the Schur algorithm and the numerator is synthesised using the polynomial expansion algorithm with the orthonormal functions obtained from the denominator. The Schur expansion of a polynomial is implemented in the Octave function *schurexpand*. The C++ *oct*-file *schurexpand.cc* implements *schurexpand* with the *MPFR* arbitrary precision floating point library [75, 126] written by *Fousse et al.* [1]. The mantissa precision is set to 256 bits.

5.1.4 Power calculation using the Schur algorithm

For the lattice filter structure in Figure 5.1, when the input signal is random and white with unit power then the average power at internal node p is

$$P_p = \langle P(z), P(z) \rangle$$

Since the denominator $D_N(z)$ is a Schur polynomial,

$$P(z) = \sum_i c_i \Phi_i(z)$$

and, since the Schur algorithm inner product is linear and orthonormal

$$P_p = \sum_i c_i^2$$

5.2 Derivation of Digital Lattice Filters

The Schur polynomials are obtained by the degree reduction procedure

$$\Phi_{i-1}(z) = \frac{z^{-1} \{\Phi_i(z) - k_i \Phi_i^*(z)\}}{s_i} \quad (5.1)$$

where s_i is a scaling factor and $k_i = \Phi_i(0) / \Phi_i^*(0)$. Note that the s_i cancel out when calculating k_i so the k_i are the same regardless of the choice of s_i . If $s_i = \sqrt{1 - k_i^2}$ then the Schur polynomials are orthonormal. In the following the i -th order Schur polynomial with this choice of s_i is denoted $\Phi_i(z)$; if $s_i = 1 - \epsilon_i k_i$ is chosen, by Λ_i , and if $s_i = 1 - k_i^2$ is chosen, by $\Psi_i(z)$.

Note that since

$$\begin{aligned} \Phi_{i-1}^*(z) &= z^{i-1} \Phi_{i-1}(z^{-1}) \\ &= \frac{\Phi_i^*(z) - k_i \Phi_i(z)}{s_i} \end{aligned}$$

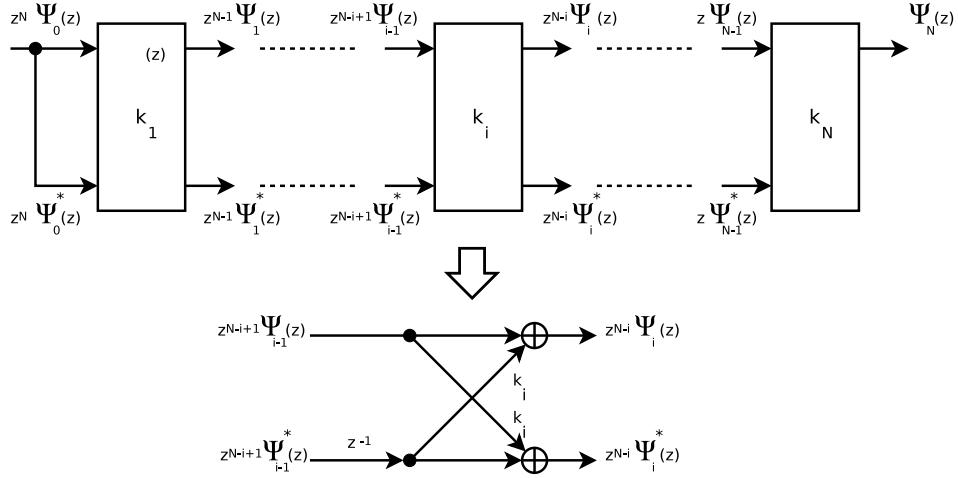

Figure 5.2: FIR filter structure (after Parhi [73, Fig. 12.8])

by rearranging

$$\begin{aligned}\Phi_i(z) &= \frac{s_i}{1 - k_i^2} \{z\Phi_{i-1}(z) + k_i\Phi_{i-1}^*(z)\} \\ \Phi_i^*(z) &= \frac{s_i}{1 - k_i^2} \{zk_i\Phi_{i-1}(z) + \Phi_{i-1}^*(z)\}\end{aligned}$$

5.2.1 Derivation of FIR, All-Pole and All-Pass Lattice Filters

Initialise an N-th order Schur polynomial as

$$\Psi_N(z) = \sum_{i=0}^N \psi_i z^i$$

Form $\Psi_{N-1}(z)$ by degree reduction

$$\Psi_{N-1}(z) = \frac{z^{-1} \{\Psi_N(z) - k_N \Psi_N^*(z)\}}{1 - k_N^2} \quad (5.2)$$

The reverse Schur polynomial is

$$\Psi_{N-1}^*(z) = z^{N-1} \Psi_{N-1}(z^{-1}) \quad (5.3)$$

$$= \frac{\Psi_N^*(z) - k_N \Psi_N(z)}{1 - k_N^2} \quad (5.4)$$

so

$$\begin{aligned}\Psi_N^*(z) &= (1 - k_N^2) \Psi_{N-1}^*(z) + k_N \Psi_N(z) \\ &= \Psi_{N-1}^*(z) + k_N \{\Psi_N - k_N \Psi_{N-1}^*(z)\}\end{aligned} \quad (5.5)$$

Substituting Equation 5.5 into Equation 5.2

$$\Psi_{N-1}(z) = z^{-1} \{\Psi_N(z) - k_N \Psi_{N-1}^*(z)\}$$

so

$$\Psi_N(z) = z\Psi_{N-1}(z) + k_N \Psi_{N-1}^*(z) \quad (5.6)$$

and, applying the definition of the reverse polynomial

$$\Psi_N^*(z) = zk_N \Psi_{N-1}(z) + \Psi_{N-1}^*(z) \quad (5.7)$$

Equations 5.6 and 5.7 represent the FIR filter shown in Figure 5.2. This structure has twice the number of multipliers of the direct form structure. However, the structure is useful for implementing adaptive filters. Equations 5.2 and 5.4 represent the IIR filter section shown in Figure 5.3. This structure implements both an all-pole filter $\Psi_0(z)/\Psi_N(z)$ and an all-pass filter $\Psi_N^*(z)/\Psi_N(z)$. The relation between $\Phi_i(z)$ and $\Psi_i(z)$ is

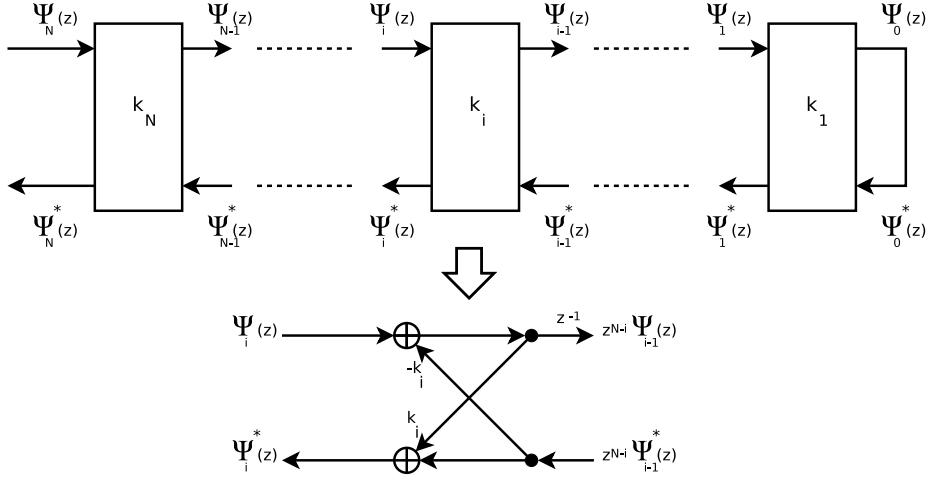

Figure 5.3: All-pass and all-pole filter structure (after Parhi [73, Fig. 12.5])

$$\begin{aligned}\Psi_N(z) &= \Phi_N(z) \\ \Phi_i(z) &= \frac{\Phi_i(z)}{\sqrt{(1-k_N^2)(1-k_{N-1}^2)\cdots(1-k_{i+1}^2)}}, \quad 0 \leq i < N\end{aligned}$$

Note that $\Phi_i(z)$ and $\Psi_i(z)$ differ only by a scale factor so the k -parameters are unchanged

$$k_i = \Psi_i(0)/\Psi_i^*(0) = \Phi_i(0)/\Phi_i^*(0)$$

Also the Ψ_i are orthogonal but not orthonormal since

$$\begin{aligned}\langle \Psi_i(z), \Psi_i(z) \rangle &= \langle \Psi_i^*(z), \Psi_i^*(z) \rangle \\ &= \frac{1}{(1-k_N^2)(1-k_{N-1}^2)\cdots(1-k_{i+1}^2)}\end{aligned}$$

Clearly, the $\langle \Psi_i(z), \Psi_i(z) \rangle$ increase as i decreases since $k_i < 1$. When most of the k -parameters are nearly one, the difference of powers among the nodes in the filter is very large and the input needs to be scaled down by a large factor to prevent overflow at a critical node. As a result the effect of roundoff noise increases significantly.

5.3 Derivation of the One-Multiplier IIR Lattice Filter

If $s_i = 1 - \epsilon_i k_i$ in Equation 5.1 then

$$\Lambda_{i-1}(z) = \frac{z^{-1} \{ \Lambda_i(z) - k_i \Lambda_i^*(z) \}}{1 - \epsilon_i k_i}$$

where $\epsilon_i = \pm 1$ is a sign parameter. For an N -th order IIR transfer function, $H(z) = N_N(z)/D_N(z)$, initialise $\Lambda_N(z) = D_N(z)$. Then

$$\begin{aligned}\Lambda_{N-1}(z) &= \frac{z^{-1} \{ \Lambda_N(z) - k_N \Lambda_N^*(z) \}}{1 - \epsilon_N k_N} \\ \Lambda_{N-1}^*(z) &= \frac{\Lambda_N^*(z) - k_N \Lambda_N(z)}{1 - \epsilon_N k_N}\end{aligned}$$

where $k_i = \Lambda_i(0)/\Lambda_i^*(0)$. Rearranging

$$\Lambda_N^*(z) = k_N \Lambda_N(z) + (1 - \epsilon_N k_N) \Lambda_{N-1}^*(z) \quad (5.8)$$

$$\Lambda_{N-1}(z) = z^{-1} \{ (1 + \epsilon_N k_N) \Lambda_N - k_N \Lambda_{N-1}^*(z) \} \quad (5.9)$$

By repeated application for $i = N, N-1, \dots, 1$, the denominator $D_N(z)$ is synthesised. The relation between $\Lambda_i(z)$ and $\Phi_i(z)$ is

$$\Lambda_N(z) = \Phi_N(z)$$

$$\Lambda_i(z) = \Phi_i(z) \sqrt{\frac{(1 + \epsilon_N k_N)(1 + \epsilon_{N-1} k_{N-1}) \cdots (1 + \epsilon_{i+1} k_{i+1})}{(1 - \epsilon_N k_N)(1 - \epsilon_{N-1} k_{N-1}) \cdots (1 - \epsilon_{i+1} k_{i+1})}}$$

where $0 \leq i < N$. Note that $\Phi_i(z)$ and $\Lambda_i(z)$ differ only by a scale factor so the k -parameters are unchanged

$$k_i = \Lambda_i(0) / \Lambda_i^*(0) = \Phi_i(0) / \Phi_i^*(0)$$

Also the Λ_i are orthogonal but not orthonormal since

$$\langle \Lambda_i(z), \Lambda_i(z) \rangle = \langle \Lambda_i^*(z), \Lambda_i^*(z) \rangle \quad (5.10)$$

$$= \frac{(1 + \epsilon_N k_N)(1 + \epsilon_{N-1} k_{N-1}) \cdots (1 + \epsilon_{i+1} k_{i+1})}{(1 - \epsilon_N k_N)(1 - \epsilon_{N-1} k_{N-1}) \cdots (1 - \epsilon_{i+1} k_{i+1})} \quad (5.11)$$

The magnitude of $\langle \Lambda_i(z), \Lambda_i(z) \rangle$ can be adjusted by choosing the sign parameters so the 1-multiplier lattice filter can avoid the severe input scaling of the basic lattice filter and has better round-off noise behaviour. One criterion for choosing the sign parameters is to require that the node associated with the largest k -parameter in magnitude have the largest amplitude[4]. The sign parameters are found recursively by requiring that the amplitudes at other nodes be as large as possible without exceeding the maximum value. If the maximum occurs for k_l then the recursion proceeds for $m = l-1, l-2, \dots, 0$ and again for $m = l+1, l+2, \dots, N$. The recursion is simple because:

$$\frac{\langle \Lambda_i(z), \Lambda_i(z) \rangle}{\langle \Lambda_{i+1}(z), \Lambda_{i+1}(z) \rangle} = \frac{1 + \epsilon_{i+1} k_{i+1}}{1 - \epsilon_{i+1} k_{i+1}}$$

By changing the sign parameter, this ratio can always be made smaller or larger than one.

Algorithm 5.2 One-multiplier lattice sign assignment

Assume that k_l has the largest magnitude of the k_m for $m = 1, 2, \dots, N$. Define the quantities

$$Q_m = \frac{\langle \Lambda_m(z), \Lambda_m(z) \rangle}{\langle \Lambda_l(z), \Lambda_l(z) \rangle}$$

$$q_m = \frac{1 + |k_m|}{1 - |k_m|}$$

so that $Q_l = 1$. Each Q_m should be as large as possible without exceeding Q_l . Successive ratios are:

$$\frac{Q_m}{Q_{m+1}} = \begin{cases} q_m & \text{if } \epsilon_m = \text{sgn}(k_m) \\ 1/q_m & \text{if } \epsilon_m = -\text{sgn}(k_m) \end{cases} \quad (5.12)$$

Now assign the ϵ_m :

```

for  $m = l-1, l-2, \dots, 1$  do
  if  $Q_{m+1} < 1/q_m$  then
     $\epsilon_m = -\text{sgn}(k_m)$ 
  else
     $\epsilon_m = \text{sgn}(k_m)$ 
  end if
end for
for  $m = l+1, l+2, \dots, N$  do
  if  $Q_m < 1/q_m$  then
     $\epsilon_m = \text{sgn}(k_m)$ 
  else
     $\epsilon_m = -\text{sgn}(k_m)$ 
  end if
end for
```

Since the polynomials $\{\Lambda_N(z), \Lambda_{N-1}(z), \dots, \Lambda_0(z)\}$ form an orthogonal basis, the numerator polynomial can be synthesised as

$$N_N(z) = \sum_{i=0}^N c_i \Lambda_i(z)$$

The synthesised filter structure is shown in Figure 5.4. The Octave function *tf2schurOneMlattice* calculates the coefficients of the one-multiplier Schur lattice from the transfer function.

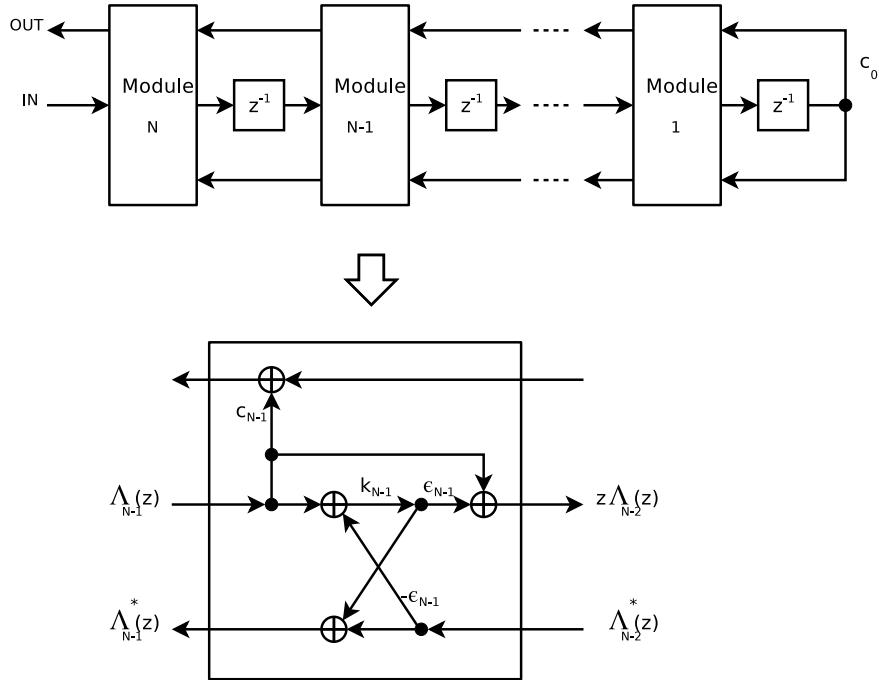

Figure 5.4: One-multiplier lattice structure (after Parhi [73, Fig. 12.11])

5.4 Derivation of the Normalised Lattice Filter

For an N-th order IIR transfer function $H_N(z) = N_N(z)/D_N(z)$ initialise the N-th order Schur polynomial as $\Phi_N(z) = D_N(z)$ and

$$\Phi_N(z) = \sum_{i=0}^N \phi_i z^i$$

Form $\Phi_{N-1}(z)$ by degree reduction

$$\Phi_{N-1}(z) = \frac{z^{-1} \{\Phi_N(z) - k_N \Phi_N^*(z)\}}{\sqrt{1 - k_N^2}}$$

where $k_i = \Phi_i(0)/\Phi_i^*(0)$. The reverse polynomial is

$$\begin{aligned} \Phi_{N-1}^*(z) &= z^{N-1} \Phi_{N-1}(z^{-1}) \\ &= \frac{\Phi_N^*(z) - k_N \Phi_N(z)}{\sqrt{1 - k_N^2}} \end{aligned}$$

So

$$\Phi_N^*(z) = \sqrt{1 - k_N^2} \Phi_{N-1}^*(z) + k_N \Phi_N(z) \quad (5.13)$$

$$\Phi_{N-1}(z) = z^{-1} \left\{ \sqrt{1 - k_N^2} \Phi_N(z) - k_N \Phi_{N-1}^*(z) \right\} \quad (5.14)$$

$$\Phi_N(z) = \frac{1}{\sqrt{1 - k_N^2}} \{ z \Phi_{N-1}(z) + k_N \Phi_{N-1}^*(z) \} \quad (5.15)$$

Figure 5.5 shows an implementation of Equations 5.13 and 5.15.

For module i

$$\begin{aligned} \sigma_{20}^{(i)} &= -\sigma_{02}^{(i)} = k_i \\ \sigma_{00}^{(i)} &= \sigma_{22}^{(i)} = \sqrt{1 - k_i^2} \end{aligned}$$

These equations synthesise the denominator $D_N(z)$ of the transfer function. The numerator is expanded in the orthonormal basis

$$N_N(z) = \sum_{i=0}^N c_i \Phi_i(z)$$

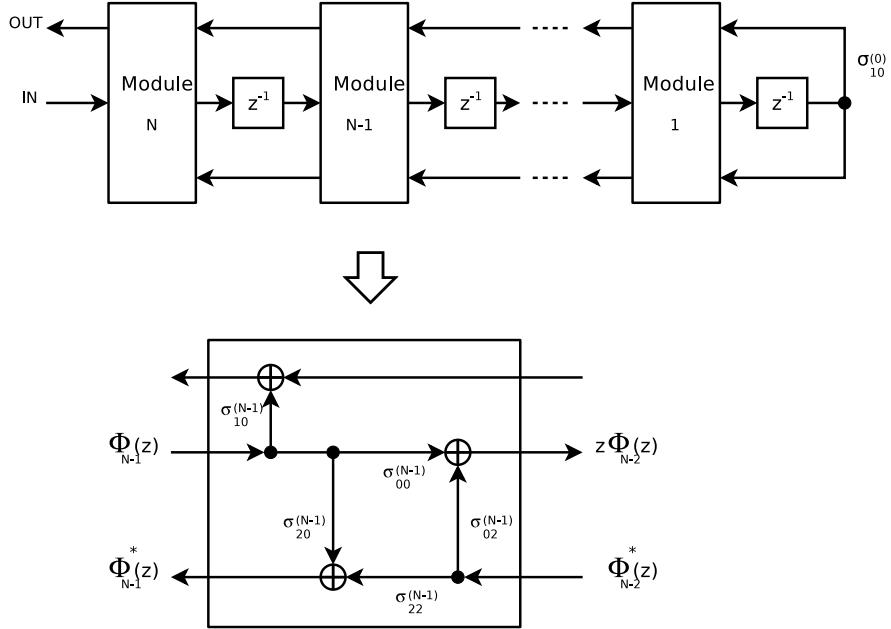

Figure 5.5: Normalised lattice filter (after Parhi [73, Fig. 12.20])

$$\sigma_{10}^{(i)} = c_i$$

This is a *normalised* lattice filter. The nodes in the feedback path have unit power since the $\Phi_i(z)$ form an orthonormal basis. For an all-pole filter the state covariance matrix, K , is the unit matrix and the structure is orthonormal. However, for a pole-zero filter the states corresponding to the numerator part are not scaled and the filter is not orthonormal.

5.5 Derivation of the Scaled Normalised Lattice Filter

We can introduce a delay at each node in the normalised lattice by making the transformation $z \rightarrow z^2$ and retiming so that each node corresponds to a state in the state variable description. Figure 5.6 shows one module of the retimed, slowed lattice. The state-variable description of the re-timed and pipelined lattice has a state for every node so that the signal at each node can be scaled^a. The orthogonality of the $\Phi_i(z)$ means that the additional diagonal elements of the state covariance matrix have the form $\sum c_i^2$. The elements of the diagonal scaling matrix have the form $T = \sqrt{\sum c_i^2}$. This suggests the following section-by-section scaling:

1. For module N:

$$\sigma_{10}^{(N)} = c_N \quad (5.16)$$

$$\sigma_{11}^{(N)} = \sqrt{\sum_{j=0}^N c_j^2} \quad (5.17)$$

2. For modules $N - 1$ to 1:

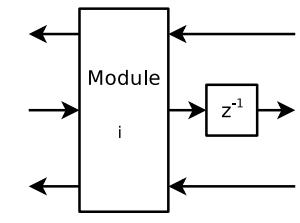

$$\sigma_{10}^{(i)} = \frac{c_i}{\sqrt{\sum_{j=0}^i c_j^2}} \quad (5.18)$$

$$\sigma_{11}^{(i)} = \frac{\sqrt{\sum_{j=0}^{i-1} c_j^2}}{\sqrt{\sum_{j=0}^i c_j^2}} \quad (5.19)$$

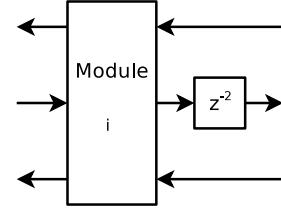

3. Any module N to 1:

$$\sigma_{20}^{(i)} = -\sigma_{02}^{(i)} = k_i \quad (5.20)$$

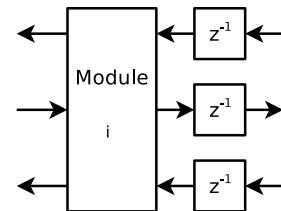

$$\sigma_{00}^{(i)} = \sigma_{22}^{(i)} = \sqrt{1 - k_i^2} \quad (5.21)$$

(a) Original lattice section

(b) After slow-down

(c) After slow-down and re-timing

Figure 5.6: Slowed and retimed lattice section

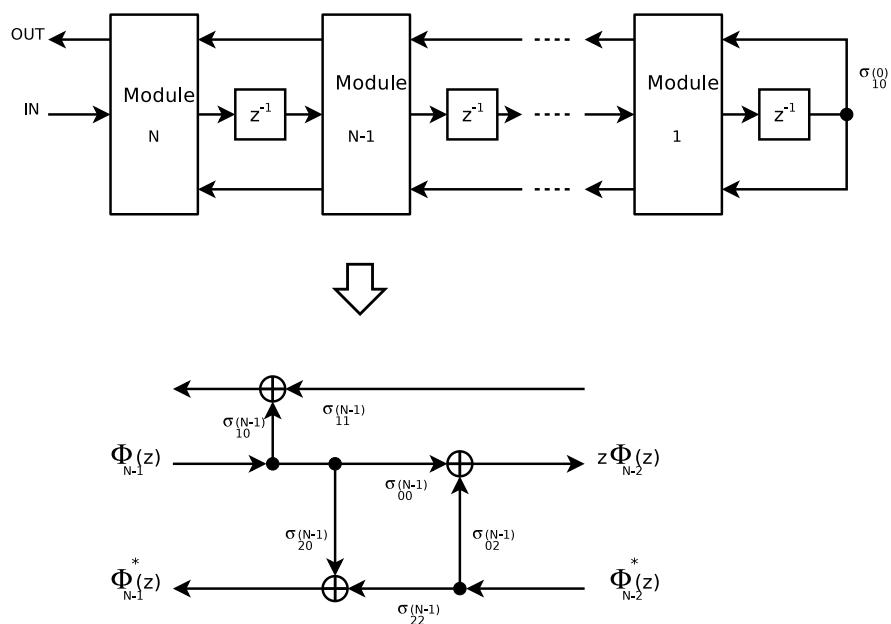

Figure 5.7: Normalised-scaled lattice filter (after Parhi [73, Fig. 12.19])

The structure of an N-th order normalised-scaled lattice filter is shown in Figure 5.7. Note that $\sigma_{10}^{(0)} = \text{sign } c_0$. The Octave function `schurNSscale` implements the scaling of the σ_{10} and σ_{11} lattice coefficients from the c_i expansion coefficients. For convenience, `schurNSscale` combines $\sigma_{10}^{(0)}$ and $\sigma_{11}^{(1)}$. The Octave function `tf2schurNSlattice` calculates the coefficients of the normalised-scaled Schur lattice from the transfer function.

5.5.1 Example: synthesis of a 3rd order Butterworth lattice filter

Parhi [73, Example 12.6.1] uses as an example a third order Butterworth low-pass filter with cutoff at angular frequency 0.1π (where the sampling frequency is normalised to 2π). The squared magnitude of the n -th order Butterworth response is defined to be

$$|\hat{H}(\omega)|^2 = \left[1 + \left(\frac{\omega}{\omega_c} \right)^{2n} \right]^{-1}$$

The poles of the response are evenly distributed around the unit circle. For stability, we choose the poles in the left-hand s -plane, $\lambda_k = \omega_c e^{i\theta_k}$, $\theta_k = \frac{\pi}{2} \left(1 + \frac{(2k-1)}{n} \right)$ with $1 \leq k \leq n$ and:

$$\hat{H}(s) = \frac{-\lambda_0 \lambda_1 \lambda_1^*}{(s - \lambda_0)(s - \lambda_1)(s - \lambda_1^*)}$$

where $\lambda_0 = \Omega_c$, the cutoff frequency of the analog low pass filter, and: $\lambda_1 = -\Omega_c \left[(1 - i\sqrt{3})/2 \right]$ so:

$$\hat{H}(s) = \frac{\Omega_c^3}{(s + \Omega_c)(s^2 + s\Omega_c + \Omega_c^2)}$$

Choose the bi-linear transformation from the s -plane to the z -plane so that the transfer function of the digital filter is $H(z) = \hat{H}\left(\frac{z-1}{z+1}\right)$. If the cutoff frequency of the digital filter $H(z)$ is $\theta_c = \omega_c t_0$ (where ω_c is the s -plane cutoff angular frequency and t_0 is the sampling interval) then *pre-warp* the s -plane frequency axis so that the corresponding cut-off in the s -plane is:

$$\Omega(\omega_c) = \tan(\omega_c t_0/2)$$

(found by substituting $z = e^{i\omega t_0}$ into the bi-linear transformation). For the third order Butterworth filter:

$$H(z) = \frac{\Omega^3(z+1)^3}{[(1+\Omega)z + (-1+\Omega)][(1+\Omega+\Omega^2)z^2 + (-2+2\Omega^2)z + (1-\Omega+\Omega^2)]}$$

In the example, the cut-off frequency is $0.05/t_0$ so $\omega_c t_0 = 0.1\pi$ and $\Omega = 0.158384$ giving:

$$H(z) = \frac{0.0028982(z+1)^3}{z^3 - 2.37409z^2 + 1.92836z - 0.53208} = \frac{(z+1)^3}{345.04z^3 - 819.16z^2 + 665.71z - 183.59}$$

For the denominator of $H(z)$ the Schur basis is:

$$\begin{aligned} \Phi_3(z) &= 345.1z^3 - 819.3z^2 + 665.8z - 183.6 \\ \Phi_2(z) &= 292.2072z^2 - 549.2662z + 271.5337 \\ \Phi_1(z) &= 107.956z - 105.1841 \\ \Phi_0(z) &= 24.3064 \end{aligned}$$

The Schur expansion of the numerator polynomial of $H(z)$ is:

1. For $H(z)$ initialise $Q(z) = z^3 + 3z^2 + 3z + 1$. Then $c_3 = 1/345.1 = 0.0029$.
2. Update $Q(z) = 5.3741z^2 + 1.0707z + 1.532$. Then $c_2 = 5.3741/292.2072 = 0.0184$.
3. Update $Q(z) = 11.1725z - 3.4619$. Then $c_1 = 11.1725/107.956 = 0.10349$.
4. Update $Q(z) = 7.4238$. Then $c_0 = 7.4238/24.3064 = 0.3054$

The sum of the expansion coefficients, the output signal power, is 0.1043. The lattice “reflection coefficients” are $k_3 = -0.532$, $k_2 = 0.9293$ and $k_1 = -0.9743$.

Figure 5.8 shows the signal-flow graph of the normalised-scaled lattice implementation of $H(z)$.

^aThe roundoff-noise performance of the transformed filter is the same as that of the original filter

Figure 5.8: Butterworth 3rd order normalised-scaled lattice filter example (after Parhi [73, Fig. 12.20])

5.6 State Variable Descriptions for Schur Lattice Filters

5.6.1 State variable description of the Schur FIR lattice filter

Figure 5.2 shows the Schur FIR lattice structure. For convenience, call x'_n the input to state x_n of the n -th section, y_n the upper output of the n -th section and y_n^* the lower output of the n -th section. Construction of the state variable description of the Schur FIR lattice is summarised in Algorithm 5.3.

Algorithm 5.3 Construction of a state variable description of the Schur FIR lattice filter

```

 $y_0 = u$ 
 $y_0^* = u$ 
for  $n = 1, \dots, N$  do
     $x'_n = y_{n-1}^*$ 
     $y_n = k_n x_n + y_{n-1}$ 
     $y_n^* = x_n + k_n y_{n-1}$ 
end for
 $y = y_N$ 

```

As shown in Section 1.12.2, the state variable description can be expressed as a series of matrix multiplications linking the input and state outputs to the output and the next state inputs.

$$\begin{bmatrix} y_0 \\ y_0^* \\ x_1 \\ \vdots \\ x_N \end{bmatrix} = \begin{bmatrix} 0 & \cdots & 0 & 1 \\ 0 & \cdots & 0 & 1 \\ 1 & \cdots & 0 & 0 \\ \vdots & \ddots & & \vdots \\ 0 & \cdots & 1 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_N \\ u \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ y_1 \\ y_1^* \\ x_2 \\ \vdots \\ x_N \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 & 0 & \cdots & 0 \\ 1 & 0 & k_1 & 0 & \cdots & 0 \\ k_1 & 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 1 & \cdots & 0 \\ \vdots & & & \ddots & & \vdots \\ 0 & \cdots & & \cdots & 1 \end{bmatrix} \begin{bmatrix} y_0 \\ y_0^* \\ x_1 \\ x_2 \\ \vdots \\ x_N \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ x'_2 \\ y_2 \\ y_2^* \\ x_3 \\ \vdots \\ x_N \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & 0 & \cdots & 0 \\ 0 & 1 & 0 & k_2 & 0 & \cdots & 0 \\ 0 & k_2 & 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 0 & 1 & \cdots & 0 \\ \vdots & & & & \ddots & & \vdots \\ 0 & \cdots & & & \cdots & 1 \end{bmatrix} \begin{bmatrix} x'_1 \\ y_1 \\ y_1^* \\ x_2 \\ x_3 \\ \vdots \\ x_N \end{bmatrix}$$

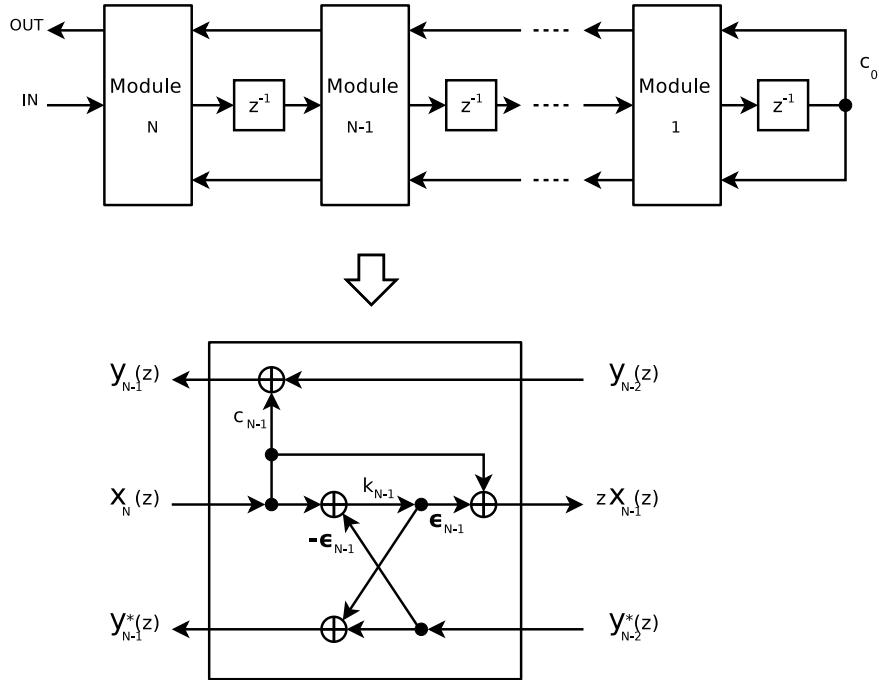

Figure 5.9: State variable description of the Schur one-multiplier lattice filter

$$\begin{bmatrix} x'_1 \\ \vdots \\ x'_{N-1} \\ y_{N-1} \\ y_{N-1}^* \\ x_N \end{bmatrix} = \begin{bmatrix} 1 & \cdots & & \cdots & 0 \\ \vdots & \ddots & & & \vdots \\ 0 & \cdots & 0 & 1 & 0 & 0 \\ 0 & \cdots & 1 & 0 & k_{N-1} & 0 \\ 0 & \cdots & k_{N-1} & 0 & 1 & 0 \\ 0 & \cdots & 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x'_1 \\ \vdots \\ y_{N-2} \\ y_{N-2}^* \\ x_{N-1} \\ x_N \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ \vdots \\ x'_N \\ y_N \\ y_N^* \end{bmatrix} = \begin{bmatrix} 1 & 0 & \cdots & \cdots & 0 \\ \vdots & \ddots & & & \vdots \\ 0 & & 0 & 1 & 0 \\ 0 & & k_N & 0 & 1 \\ 0 & \cdots & 1 & 0 & k_N \end{bmatrix} \begin{bmatrix} x'_1 \\ \vdots \\ y_{N-1} \\ y_{N-1}^* \\ x_N \end{bmatrix}$$

The Octave function `schurFIRlattice2Abcd` returns the state variable description of a Schur FIR lattice filter.

5.6.2 State variable description of the one-multiplier IIR lattice filter

In Figure 5.9, Figure 5.4 is redrawn with x'_n corresponding to the input to state x_n of the n -th section, y_n being the output of the n -th section and y_n^* the all-pass output of the n -th section. Construction of the state variable description is summarised in Algorithm 5.4.

Algorithm 5.4 Construction of a state variable description of the Schur one-multiplier lattice filter

```

 $y_0^* = x_1$ 
for  $n = 1, \dots, N - 1$  do
     $x'_n = -k_n y_{n-1}^* + (1 + k_n \epsilon_n) x_{n+1}$ 
     $y_n^* = (1 - k_n \epsilon_n) y_{n-1}^* + k_n x_{n+1}$ 
end for
 $x_N = -k_N y_{N-1}^* + (1 + k_N \epsilon_N) u$ 
 $y^* = (1 - k_N \epsilon_N) y_{N-1}^* + k_N u$ 
 $y = c_0 x_1 + c_1 x_2 + \dots + c_{N-1} x_N + c_N u$ 

```

The state variable description can be expressed as a series of matrix multiplications linking the input and state outputs to the

output and the next state inputs.

$$\begin{bmatrix} y_0^* \\ x_2 \\ x_3 \\ \vdots \\ x_N \\ u \end{bmatrix} = \begin{bmatrix} 1 & 0 & \cdots & \cdots & 0 \\ 0 & 1 & & & \vdots \\ \vdots & \ddots & & & \vdots \\ & & \ddots & & \vdots \\ 0 & & & 1 & 0 \\ 0 & \cdots & \cdots & 0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_N \\ u \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ y_1^* \\ x_3 \\ \vdots \\ x_N \\ u \end{bmatrix} = \begin{bmatrix} -k_1 & (1+k_1\epsilon_1) & 0 & \cdots & \cdots & 0 \\ (1-k_1\epsilon_1) & k_1 & 0 & & & \vdots \\ 0 & 0 & 1 & & & \vdots \\ \vdots & & & \ddots & & \vdots \\ 0 & & & & 1 & 0 \\ 0 & \cdots & \cdots & 0 & 1 \end{bmatrix} \begin{bmatrix} y_0^* \\ x_2 \\ x_3 \\ \vdots \\ x_N \\ u \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ x'_2 \\ y_2^* \\ \vdots \\ x_N \\ u \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & \cdots & 0 \\ 0 & -k_2 & (1+k_2\epsilon_2) & 0 & & \vdots \\ 0 & (1-k_2\epsilon_2) & k_2 & 0 & & \vdots \\ \vdots & & & \ddots & & \vdots \\ 0 & & & & 1 & 0 \\ 0 & \cdots & \cdots & 0 & 1 \end{bmatrix} \begin{bmatrix} x'_1 \\ y_1^* \\ x_3 \\ \vdots \\ x_N \\ u \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ x'_2 \\ \vdots \\ x'_{N-1} \\ y_{N-1}^* \\ u \end{bmatrix} = \begin{bmatrix} 1 & 0 & \cdots & & \cdots & 0 \\ 0 & 1 & & & & \vdots \\ \vdots & \ddots & & & & \vdots \\ 0 & & -k_{N-1} & (1+k_{N-1}\epsilon_{N-1}) & 0 & x'_1 \\ 0 & & (1-k_{N-1}\epsilon_{N-1}) & k_{N-1} & 0 & \vdots \\ 0 & \cdots & 0 & 0 & 1 & x'_{N-2} \\ 0 & \cdots & \cdots & 0 & 0 & y_{N-2}^* \\ 0 & \cdots & \cdots & 0 & 1 & x_N \\ 0 & \cdots & \cdots & 0 & 0 & u \end{bmatrix} \begin{bmatrix} x'_1 \\ \vdots \\ x'_{N-2} \\ y_{N-2}^* \\ x_N \\ u \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ x'_2 \\ x'_3 \\ \vdots \\ x'_N \\ y^* \end{bmatrix} = \begin{bmatrix} 1 & 0 & \cdots & \cdots & 0 \\ 0 & 1 & & & \vdots \\ \vdots & \ddots & & & \vdots \\ 0 & & 1 & 0 & 0 \\ 0 & & 0 & -k_N & (1+k_N\epsilon_N) \\ 0 & \cdots & 0 & (1-k_N\epsilon_N) & k_N \end{bmatrix} \begin{bmatrix} x'_1 \\ x'_2 \\ \vdots \\ x'_{N-1} \\ y_{N-1}^* \\ u \end{bmatrix}$$

The Octave function `schurOneMlattice2Abcd` returns the state variable description of a one multiplier lattice filter (including the all-pass filter *Cap* and *Dap* output matrixes).

5.6.3 State variable description of a retimed one-multiplier Schur lattice filter

Figure 5.10 shows a second order segment of the retimed Schur one-multiplier lattice filter in Figure 5.24b.

Construction of a state variable description of the retimed Schur one-multiplier lattice filter is summarised in Algorithm 5.5.

As in Section 5.6.2, the state variable description can be expressed as a series of matrix multiplications. For an even order filter:

$$\begin{bmatrix} y_0 \\ y_0^* \\ x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_{3\frac{N}{2}} \\ u \end{bmatrix} = \begin{bmatrix} c_0 & 0 & \cdots & \cdots & 0 \\ 1 & 0 & \cdots & \cdots & 0 \\ 1 & 0 & \cdots & \cdots & 0 \\ \vdots & \ddots & & & \vdots \\ & & \ddots & & \vdots \\ 0 & & & 1 & 0 \\ 0 & \cdots & \cdots & 0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_{3\frac{N}{2}} \\ u \end{bmatrix}$$

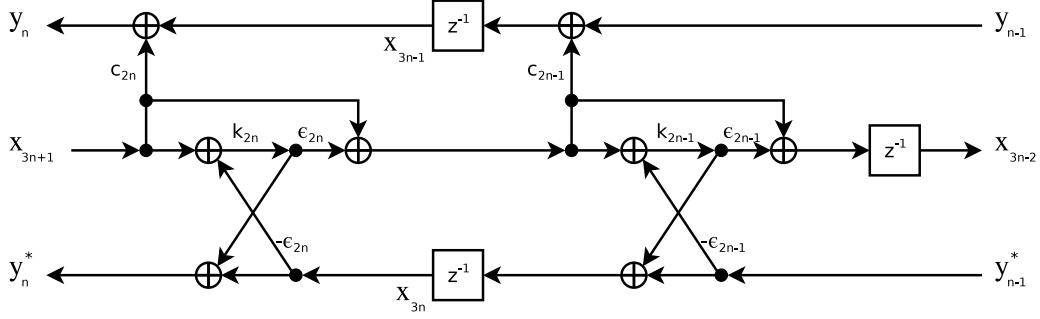

Figure 5.10: Second order segment of the retimed Schur one-multiplier lattice filter

Algorithm 5.5 Construction of a state variable description of the retimed Schur one-multiplier lattice filter

Given $\{k_1, k_2, \dots, k_N\}$, $\{\epsilon_1, \epsilon_2, \dots, \epsilon_N\}$ and $\{c_0, c_1, \dots, c_N\}$:

```

 $y_0 = c_0 x_1$ 
 $y_0^* = x_1$ 
for  $n = 1, \dots, \lceil \frac{N}{2} \rceil - 1$  do
   $x'_{3n-2} = -k_{2n-1} y_{n-1}^* - (1 + k_{2n-1} \epsilon_{2n-1}) k_{2n} x_{3n} + (1 + k_{2n-1} \epsilon_{2n-1}) (1 + k_{2n} \epsilon_{2n}) x_{3n+1}$ 
   $x'_{3n-1} = y_{n-1} - c_{2n-1} k_{2n} x_{3n} + c_{2n-1} (1 + k_{2n} \epsilon_{2n}) x_{3n+1}$ 
   $x'_{3n} = (1 - k_{2n-1} \epsilon_{2n-1}) y_{n-1}^* - k_{2n-1} k_{2n} x_{3n} + k_{2n-1} (1 + k_{2n} \epsilon_{2n}) x_{3n+1}$ 
   $y_n = x_{3n-1} + c_{2n} x_{3n+1}$ 
   $y_n^* = (1 - k_{2n} \epsilon_{2n}) x_{3n} + k_{2n} x_{3n+1}$ 
end for
if  $N$  is odd then
   $x'_{3\lceil \frac{N}{2} \rceil - 2} = -k_N y_{\lceil \frac{N}{2} \rceil - 1}^* + (1 + k_N \epsilon_N) u$ 
   $y = y_{\lceil \frac{N}{2} \rceil - 1} + c_N u$ 
   $y^* = (1 - k_N \epsilon_N) y_{\lceil \frac{N}{2} \rceil - 1}^* + k_N u$ 
else
   $x'_{3\frac{N}{2} - 2} = -k_{N-1} y_{\frac{N}{2} - 1}^* - (1 + k_{N-1} \epsilon_{N-1}) k_N x_{3\frac{N}{2}} + (1 + k_{N-1} \epsilon_{N-1}) (1 + k_N \epsilon_N) u$ 
   $x'_{3\frac{N}{2} - 1} = y_{\frac{N}{2} - 1} - c_{N-1} k_N x_{3\frac{N}{2}} + c_{N-1} (1 + k_N \epsilon_N) u$ 
   $x'_{3\frac{N}{2}} = (1 - k_{N-1} \epsilon_{N-1}) y_{\frac{N}{2} - 1}^* - k_{N-1} k_N x_{3\frac{N}{2}} + k_{N-1} (1 + k_N \epsilon_N) u$ 
   $y = x_{3\frac{N}{2} - 1} + c_N u$ 
   $y^* = (1 - k_N \epsilon_N) x_{3\frac{N}{2}} + k_N u$ 
end if

```

$$\begin{bmatrix} x'_1 \\ x'_2 \\ x'_3 \\ y_1 \\ y_1^* \\ x_4 \\ \vdots \\ x_{3\frac{N}{2}} \\ u \end{bmatrix} = \begin{bmatrix} 0 & -k_1 & 0 & 0 & -(1+k_1\epsilon_1)k_2 & (1+k_1\epsilon_1)(1+k_2\epsilon_2) & \cdots & 0 \\ 1 & 0 & 0 & 0 & -c_1k_2 & c_1(1+k_2\epsilon_2) & \cdots & 0 \\ 0 & (1-k_1\epsilon_1) & 0 & 0 & -k_1k_2 & k_1(1+k_2\epsilon_2) & \cdots & 0 \\ 0 & 0 & 0 & 1 & 0 & c_2 & \cdots & 0 \\ 0 & 0 & 0 & 0 & (1-k_2\epsilon_2) & k_2 & \cdots & 0 \\ 0 & \cdots & & & & & \ddots & \\ 0 & \cdots & & & & & \cdots & 1 & 0 \\ 0 & \cdots & & & & & \cdots & 0 & 1 \end{bmatrix} \begin{bmatrix} y_0 \\ y_0^* \\ x_1 \\ x_2 \\ x_3 \\ x_4 \\ \vdots \\ x_{3\frac{N}{2}} \\ u \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ \vdots \\ x'_{3\frac{N}{2}} \\ y \\ y^* \end{bmatrix} = \begin{bmatrix} 1 & \cdots & & & \cdots & 0 \\ \vdots & \ddots & & & & \vdots \\ 0 & \cdots & 0 & -k_{N-1} & 0 & 0 & -(1+k_{N-1}\epsilon_{N-1})k_N & (1+k_{N-1}\epsilon_{N-1})(1+k_N\epsilon_N) \\ 0 & \cdots & 1 & 0 & 0 & 0 & -c_{N-1}k_N & c_{N-1}(1+k_N\epsilon_N) \\ 0 & \cdots & 0 & 1-k_{N-1}\epsilon_{N-1} & 0 & 0 & -k_{N-1}k_N & k_{N-1}(1+k_N\epsilon_N) \\ 0 & \cdots & 0 & 0 & 0 & 1 & 0 & c_N \\ 0 & \cdots & 0 & 0 & 0 & 0 & (1-k_N\epsilon_N) & k_N \end{bmatrix} \begin{bmatrix} x'_1 \\ \vdots \\ x'_{3\frac{N}{2}-3} \\ y_{\frac{N}{2}-1} \\ y_{\frac{N}{2}-1}^* \\ x_{3\frac{N}{2}-2} \\ x_{3\frac{N}{2}-1} \\ x_{3\frac{N}{2}} \\ u \end{bmatrix}$$

For an odd order filter, the final matrix multiplication is:

$$\begin{bmatrix} x'_1 \\ \vdots \\ x'_{3\lceil\frac{N}{2}\rceil-2} \\ y \\ y^* \end{bmatrix} = \begin{bmatrix} 1 & \cdots & & \cdots & 0 \\ \vdots & \ddots & & & \vdots \\ 0 & \cdots & 0 & -k_N & 0 & (1+k_N\epsilon_N) \\ 0 & \cdots & 1 & 0 & 0 & c_N \\ 0 & \cdots & 0 & (1-k_N\epsilon_N) & 0 & k_N \end{bmatrix} \begin{bmatrix} x'_1 \\ \vdots \\ x'_{3\lceil\frac{N}{2}\rceil-3} \\ y_{\lceil\frac{N}{2}\rceil-1} \\ y_{\lceil\frac{N}{2}\rceil-1}^* \\ x_{3\lceil\frac{N}{2}\rceil-2} \\ u \end{bmatrix}$$

The Octave function `schurOneMlatticeRetimed2Abcd` returns the state variable description of a retimed Schur one-multiplier lattice filter (including the all-pass filter *Cap* and *Dap* output matrixes).

5.6.4 State variable description of the scaled-normalised IIR lattice filter

In Figure 5.11, Figure 5.7 is redrawn with x'_n corresponding to the input to state x_n of the n -th section, y_n being the output of the n -th section and y_n^* the all-pass output of the n -th section. Construction of the state variable description is summarised in Algorithm 5.6 ^b.

The state variable description can be expressed as a series of matrix multiplications linking the input and state outputs to the output and the next state inputs.

$$\begin{bmatrix} y_0^* \\ y_0 \\ x_2 \\ x_3 \\ \vdots \\ x_N \\ u \end{bmatrix} = \begin{bmatrix} 1 & 0 & \cdots & \cdots & 0 \\ \sigma_{10}^{(0)} & 0 & \cdots & & \vdots \\ 0 & 1 & & & \\ \vdots & \ddots & & \vdots & \\ 0 & & & 1 & 0 \\ 0 & \cdots & \cdots & 0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_N \\ u \end{bmatrix}$$

^bThe Octave function `schurNSlattice` combines $\sigma_{10}^{(0)}$ and $\sigma_{11}^{(1)}$

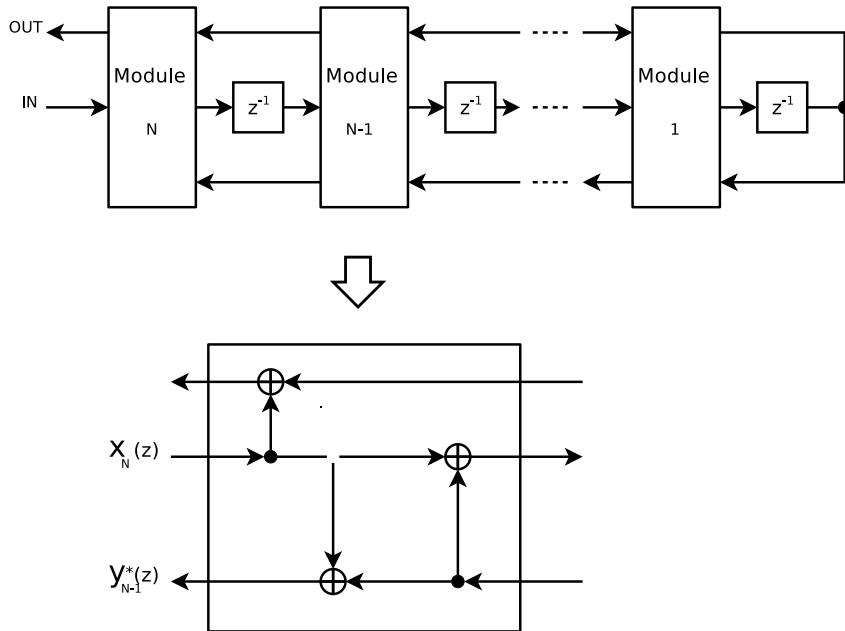

Figure 5.11: State variable description of the Schur Scaled-Normalised lattice filter

Algorithm 5.6 Construction of a state variable description of the Scaled-Normalised Lattice

     $y_n^* = \sigma_{22}^{(n)} y_{n-1}^* + \sigma_{20}^{(n)} x_{n+1}$ 
     $y_n = \sigma_{11}^{(n)} y_{n-1} + \sigma_{10}^{(n)} x_{n+1}$ 
end for
 $x'_N = \sigma_{02}^{(N)} y_{N-1}^* + \sigma_{00}^{(N)} u$ 
 $y^* = \sigma_{22}^{(N)} y_{N-1}^* + \sigma_{20}^{(N)} u$ 
 $y = \sigma_{11}^{(N)} y_{N-1} + \sigma_{10}^{(N)} u$ 

```

$$\begin{bmatrix} x'_1 \\ y_1^* \\ y_1 \\ x_3 \\ \vdots \\ x_N \\ u \end{bmatrix} = \begin{bmatrix} \sigma_{02}^{(1)} & 0 & \sigma_{00}^{(1)} & 0 & 0 & \cdots & 0 \\ \sigma_{22}^{(1)} & 0 & \sigma_{20}^{(1)} & 0 & & & \vdots \\ 0 & \sigma_{11}^{(1)} & \sigma_{10}^{(1)} & 0 & & & \\ 0 & 0 & 0 & 1 & & & \\ & & & & \ddots & & \vdots \\ & & & & & 1 & 0 \\ 0 & \dots & \dots & 0 & 1 & & \\ 0 & & & & & & \end{bmatrix} \begin{bmatrix} y_0^* \\ y_0 \\ x_2 \\ x_3 \\ \vdots \\ x_N \\ u \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ x'_2 \\ y_2^* \\ y_2 \\ \vdots \\ u \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & \sigma_{02}^{(2)} & 0 & \sigma_{00}^{(2)} & & & \vdots \\ 0 & \sigma_{22}^{(2)} & 0 & \sigma_{20}^{(2)} & & & \\ 0 & 0 & \sigma_{11}^{(2)} & \sigma_{10}^{(2)} & & & \\ & & & & \ddots & & \vdots \\ & 0 & \dots & & 0 & & \\ 0 & & & & 0 & 1 & \end{bmatrix} \begin{bmatrix} x'_1 \\ y_1^* \\ y_1 \\ x_3 \\ \vdots \\ x_N \\ u \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ x'_2 \\ \vdots \\ x'_{N-1} \\ y_{N-1}^* \\ y_{N-1} \\ u \end{bmatrix} = \begin{bmatrix} 1 & 0 & \cdots & & \cdots & 0 \\ 0 & 1 & & & & \vdots \\ \vdots & \ddots & & & & \\ 0 & & \sigma_{02}^{(N-1)} & 0 & \sigma_{00}^{(N-1)} & \\ 0 & & \sigma_{22}^{(N-1)} & 0 & \sigma_{20}^{(N-1)} & \vdots \\ 0 & & 0 & \sigma_{11}^{(N-1)} & \sigma_{10}^{(N-1)} & 0 \\ 0 & \dots & & & & \cdots \\ 0 & & & & & 1 \end{bmatrix} \begin{bmatrix} x'_1 \\ \vdots \\ y_{N-2}^* \\ y_{N-2} \\ x_N \\ u \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ x'_2 \\ x'_3 \\ \vdots \\ x'_N \\ y^* \\ y \end{bmatrix} = \begin{bmatrix} 1 & 0 & \cdots & & \cdots & 0 \\ 0 & 1 & & & & \vdots \\ \vdots & \ddots & & & & \vdots \\ 0 & & \sigma_{02}^{(N)} & 0 & \sigma_{00}^{(N)} & \\ 0 & & \sigma_{22}^{(N)} & 0 & \sigma_{20}^{(N)} & \\ 0 & & 0 & \sigma_{11}^{(N)} & \sigma_{10}^{(N)} & \end{bmatrix} \begin{bmatrix} x'_1 \\ x'_2 \\ \vdots \\ y_{N-1}^* \\ y_{N-1} \\ u \end{bmatrix}$$

The Octave function `schurNSlattice2Abcd` returns the state variable description of a normalised-scaled lattice filter (including the all-pass filter *Cap* and *Dap* output matrixes).

5.7 Roundoff Noise Calculation in Schur Lattice Filters

In the following I rely on the analysis of round-off noise in the state variable description presented by *Roberts and Mullis* [129], [21], [22]. Lattice filter roundoff noise can be calculated by the *K* and *W* matrices derived from the state variable description of the filter. An alternative method uses the Schur polynomials and the transposed graph of the filter. To compute the output roundoff noise, the transfer functions from the internal nodes to the output node are needed. These are the same as the transfer functions from the input to the internal nodes of the transposed filter. Again, these transfer functions can be derived from the Schur decomposition or the state variable description.

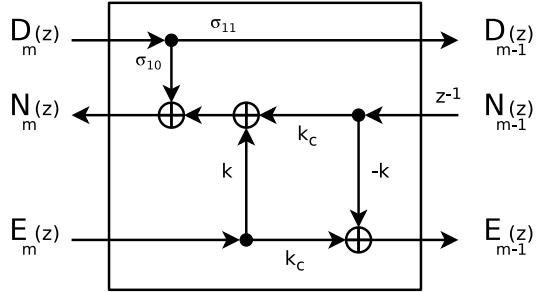

Figure 5.12: Transposed normalised-scaled lattice filter module (after Parhi [73, Fig. 12.24])

5.7.1 Round-off noise of the normalised-scaled lattice filter

Calculation of the normalised-scaled lattice filter round-off noise with the transposed signal flow graph

Figure 5.12 shows module m of $N, \dots, 1$ of the transposed graph of a normalised-scaled lattice filter (with $k = \sigma_{20} = -\sigma_{02}$, and $k_c = \sqrt{1 - k^2} = \sigma_{00} = \sigma_{22}$). The transposed graph of the module gives

$$\begin{bmatrix} z^{-1}N_{m-1}(z) \\ D_{m-1}(z) \\ E_{m-1}(z) \end{bmatrix} = \frac{1}{k_c} \begin{bmatrix} 1 & -\sigma_{10} & -k \\ 0 & k_c \sigma_{11} & 0 \\ -k & k \sigma_{10} & 1 \end{bmatrix} \begin{bmatrix} N_m(z) \\ D_m(z) \\ E_m(z) \end{bmatrix}$$

For module N , the input, $D_N(z)$, and output, $N_N(z)$, are given by the transfer function $H(z) = N(z)/D(z)$ and $E_N(z) = 0$. Similarly, for the all-pass response, $D_N(z) = 0$, $N_N(z) = z^N D(z^{-1})$ and $E_N(z) = D(z)$. The transfer function polynomials of the modules to the right hand of module N are found by repeated matrix multiplication. Since $D(z)$ is a Schur polynomial, the output noise variance due to round off at each node is calculated from the coefficients of the Schur orthonormal basis decomposition of these transfer function polynomials.

The Octave script *butt3NS_test.m* uses the transposed transfer function to calculate the round-off noise of the normalised-scaled 3rd order low-pass Butterworth filter of the example in Section 5.5.1. The coefficients of the lattice are exact, not truncated. Coefficient truncation implies a different Schur basis and the polynomial division used to find the output noise is inaccurate. Annotated output from *butt3NS_test.m* follows.

The filter cutoff frequency is

$f_c = 0.050000$

The denominator and numerator polynomials are

$n = 0.0028982 \quad 0.0086946 \quad 0.0086946 \quad 0.0028982$

$d = 1.00000 \quad -2.37409 \quad 1.92936 \quad -0.53208$

The Schur orthonormal basis corresponding to the denominator polynomial is

$s =$	0.07045	0.00000	0.00000	0.00000
	-0.30483	0.31286	0.00000	0.00000
	0.78677	-1.59152	0.84670	0.00000
	-0.53208	1.92936	-2.37409	1.00000

The Schur expansion of the numerator polynomial is

$c = 0.3053850 \quad 0.1034929 \quad 0.0183952 \quad 0.0028982$

The coefficients of filter sections (input/output at the right end of each vector) are

```

s10 = 0.3209629 0.0569565 0.0028982
s11 = 0.94709 0.99838 0.32297
s20 = -0.97432 0.92923 -0.53208
s00 = 0.22518 0.36951 0.84670
s02 = 0.97432 -0.92923 0.53208
s22 = 0.22518 0.36951 0.84670

```

The noise gain of the filter (with un-quantised coefficients) is

```
ng = 1.1906
```

The nodes corresponding to $D_0(z)$ and $E_0(z)$, that is at the output of state x_1 , make no contribution to round-off noise and are omitted from the noise gain. The noise gain can be reduced slightly by summing the output in one pass (assuming a double-length accumulator holds the intermediate sums along the top edge of Figure 5.8).

The noise gain of the associated all-pass filter is

```
ngap = 5.0000
```

Recall that for a unit variance white noise input the internal nodes of the normalised-scaled filter have unit signal variance and that the transfer functions from the internal nodes of the all-pass filter to the all-pass output have unity gain by definition. Therefore the noise gain of the all-pass filter is simply the number of internal nodes at which arithmetic truncation occurs. In this case there are five internal nodes in the all-pass filter at which round-off occurs. Three of these are at the inputs to the internal delay element state storage and two are at calculation of the reverse Schur polynomial output, $\Phi_i^*(z)$. By convention the third of the reverse Schur polynomial output truncations is represented separately as the all-pass filter output truncation. (Truncation of the internal reverse Schur polynomial outputs could be avoided by storing them in temporary double precision storage).

For comparison the noise gain of a globally optimised Butterworth filter is $ngopt = 0.47049$ and for a direct form implementation, $ngdir = 68.980$. The corresponding noise gains for the globally optimised and direct-form all-pass filters are $ngoptap = 3.0000$ and $ngdirap = 818.90$.

The filters were tested with a uniformly distributed random noise signal with variance 0.5 of full-scale. The filter outputs were calculated with floating point arithmetic and again with rounding-to-nearest truncation and 10 bit word storage.

Figure 5.13 shows the frequency response of the Schur lattice implementation of the Butterworth filter and all-pass filter determined from the cross-correlation of the filter input and outputs.

The estimated and simulated round-off noise variances are for the Schur lattice implementation of the Butterworth filter ($\sigma^2 = (1 + ng)/12$):

```

est_varyd = 0.18255
varyd = 0.18266

```

and for the Schur lattice all-pass filter

```

est_varyapd = 0.50000
varyapd = 0.49645

```

Similarly, the estimated and simulated round-off noise variances for the globally optimised Butterworth filter are:

```

est_varyoptd = 0.12254
varyoptd = 0.12191

```

and the estimated and simulated round-off noise variances for the scaled direct-form Butterworth filter are:

```

est_varydird = 5.8317
varydird = 1.8078

```

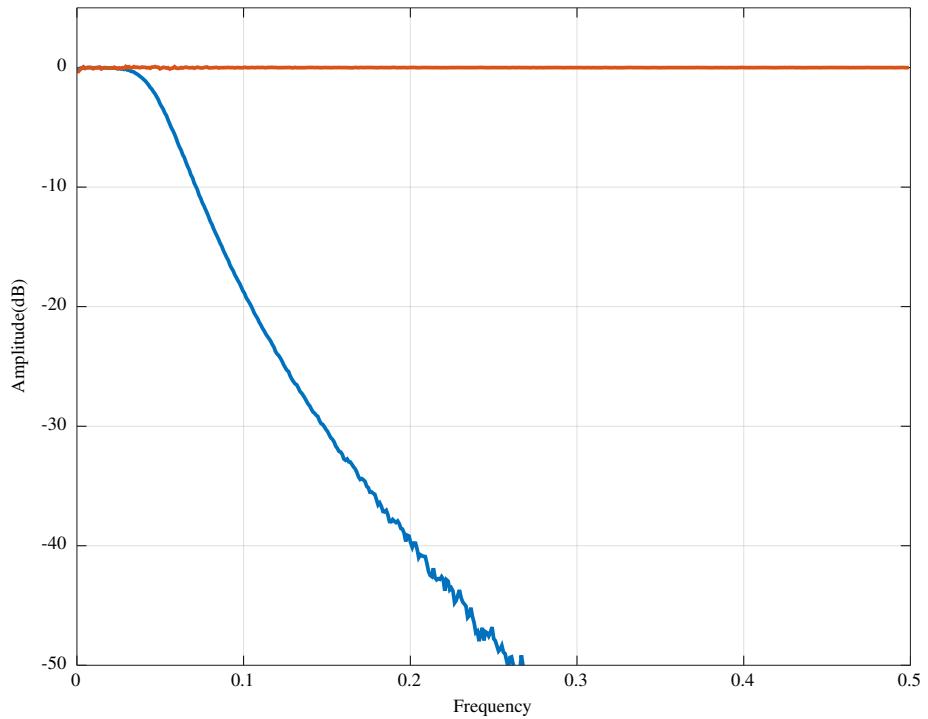

Figure 5.13: Frequency response of the 3rd order Butterworth filter implemented with a normalised-scaled lattice structure

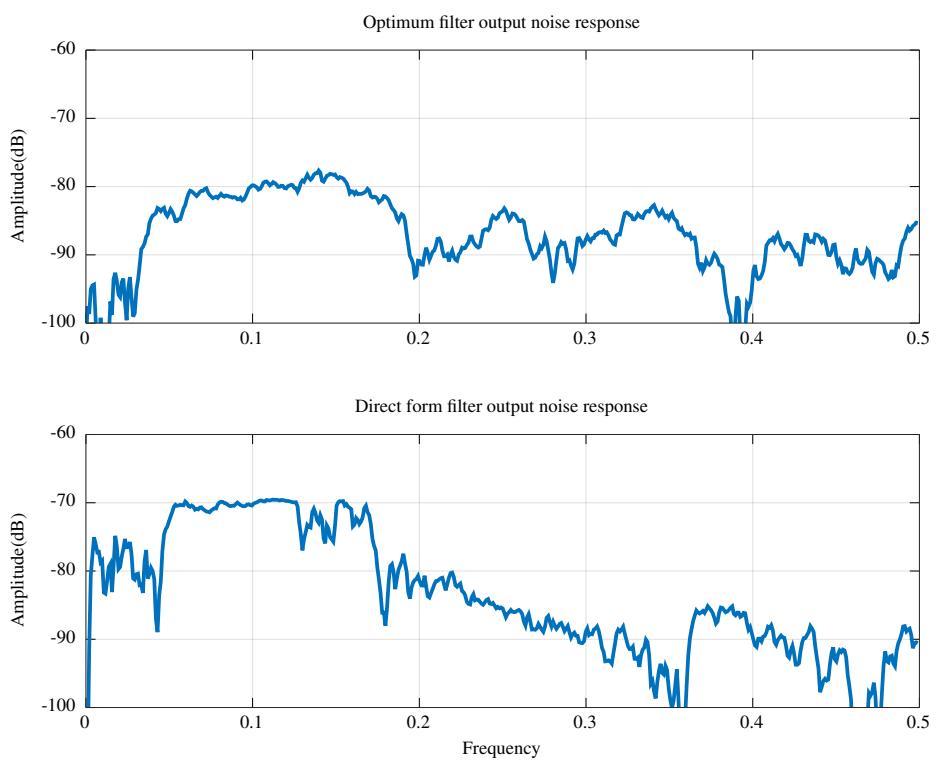

Figure 5.14: Comparison of the frequency response of the output noise of the 3rd order Butterworth filter when implemented with a scaled direct-form and globally optimised state variable structure

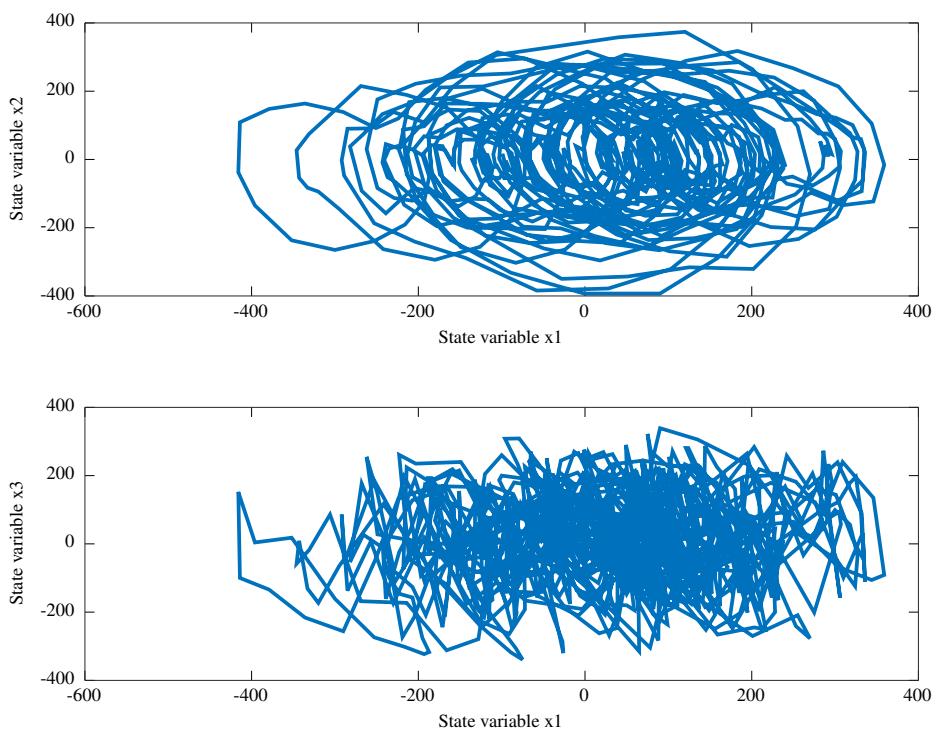

Figure 5.15: Internal states in the 3rd order Butterworth filter implemented in a normalised-scaled Schur lattice structure with a random noise input

The factor of about 3 discrepancy between the estimated and measured output roundoff noise of the scaled direct-form filter suggests that the output roundoff noise of that filter is correlated with the input signal rather than having the uniform random distribution assumed in the noise calculations. Figure 5.14 compares the response of the output roundoff noise of the scaled direct-form implementation to that of the globally optimised filter.

The standard deviations of the internal states of the Schur lattice filter are

```
stdxx = 131.32 129.47 127.97
```

The standard deviations of the internal states of the globally-optimum and scaled direct-form filters are similar. Figures 5.15, 5.16 and 5.17 show part of the state trajectories for the Schur lattice, globally-optimised and direct-form state variable versions of the Butterworth filter with a random noise input.

Figure 5.18 shows part of the state trajectories for the Schur lattice implementation of the Butterworth filter in response to a sine wave input.

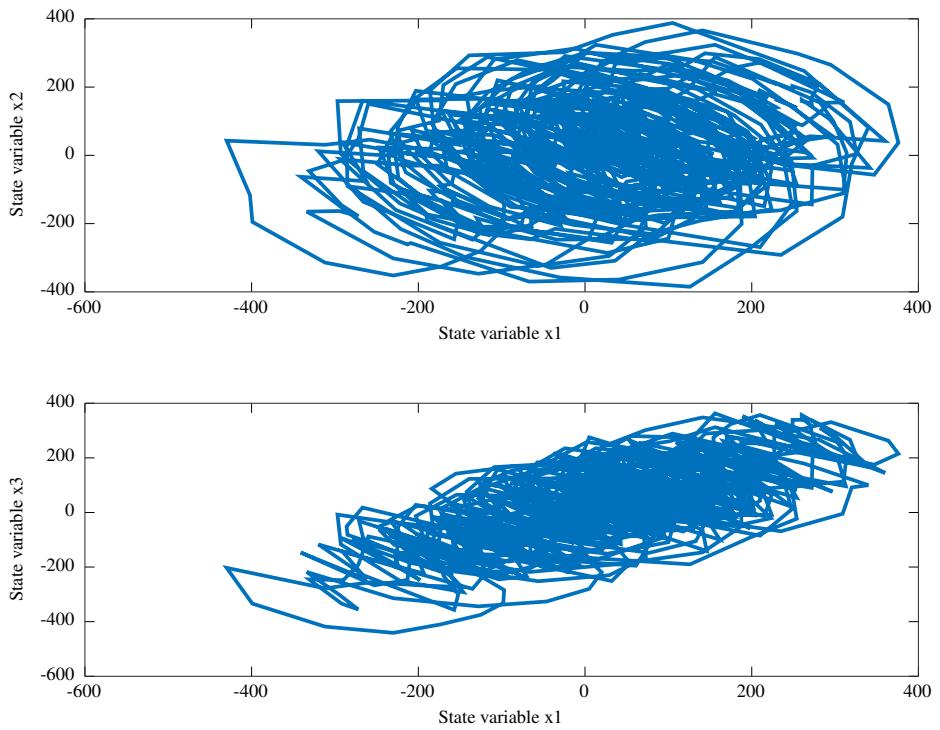

Figure 5.16: Internal states in the 3rd order Butterworth filter implemented in the globally optimised state variable structure with a random noise input

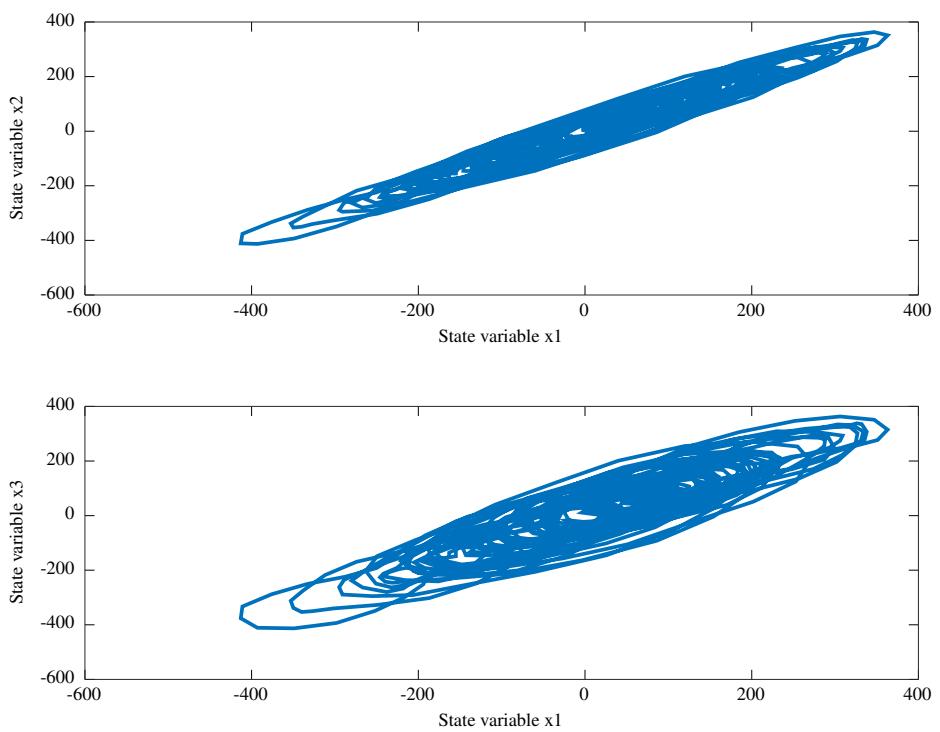

Figure 5.17: Internal states in the 3rd order Butterworth filter implemented in a direct-form structure with a random noise input

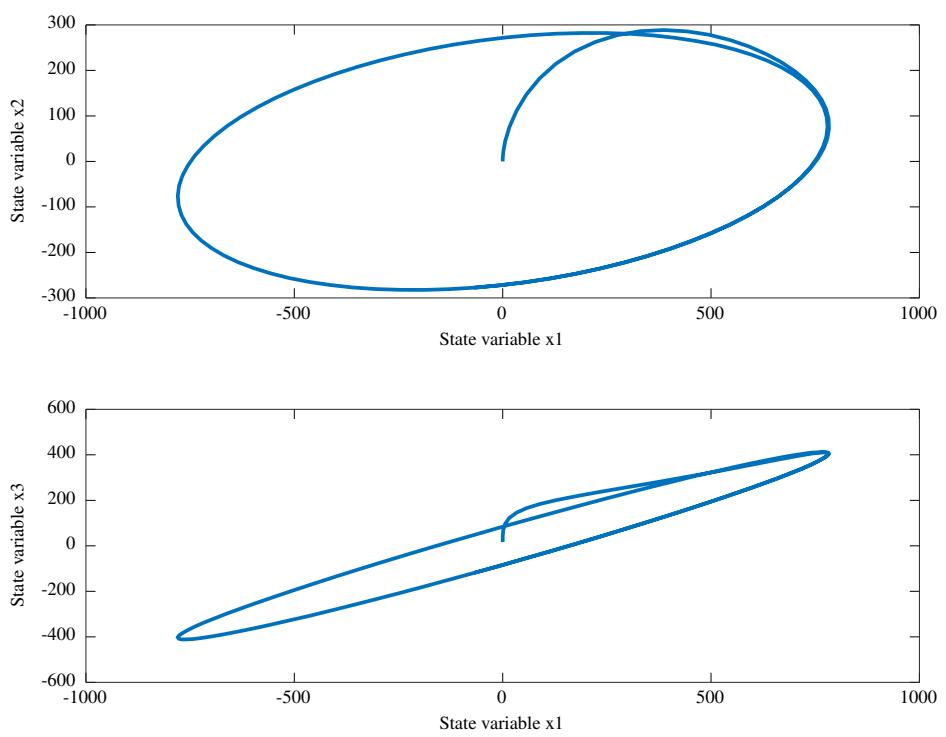

Figure 5.18: Internal states in the 3rd order Butterworth filter implemented with a Schur lattice structure with a sine wave input

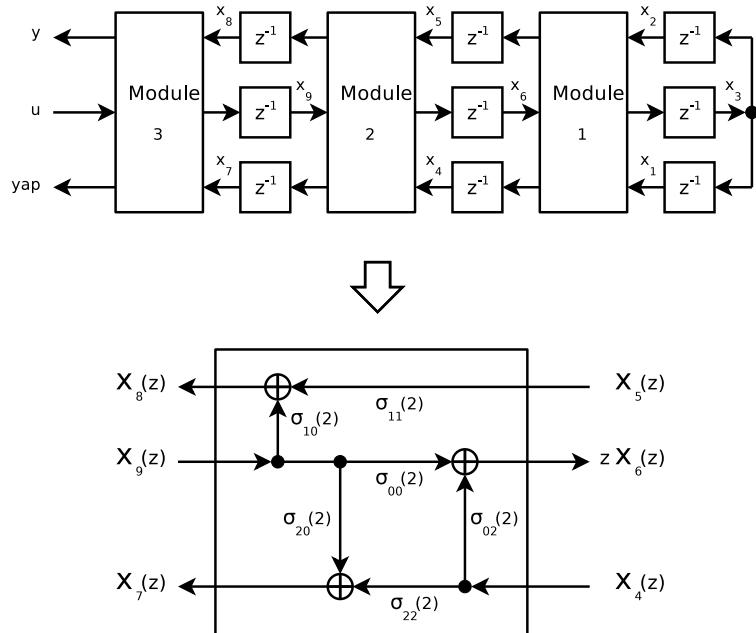

Figure 5.19: Slowed and retimed normalised-scaled lattice for the 3rd order Butterworth example

Calculation of the normalised-scaled lattice filter round-off noise with a retimed state-variable description

Parhi [73, Chapter 12, p. 450] suggests that the normalised-scaled lattice filter round-off noise variance can also be determined from the state variable representation if the filter is slowed and retimed as shown in Figure 5.19. Each intermediate node is now associated with a state. The additional states alter the overall transfer function but the round-off noise gains are unchanged.

The Octave function `schurNSLatticeRetimedNoiseGain` converts the Schur normalised-scaled lattice implementation to a retimed state variable form used to calculate the noise gains. The Octave script `butt3NSSV_test.m` demonstrates roundoff noise calculations in the retimed state variable form. The Butterworth and all-pass filter noise gains with exact coefficients are found to be the same as those for the transposed filter calculation above. With 10 bit 2 signed-digit coefficients the retimed state variable form of the Schur lattice Butterworth and all-pass filters have noise gains $ng = 1.1334$ and $ngap = 5.6989$. The equivalent floating point signed-digit coefficients are calculated by the Octave function `flt2SD` which calls `bin2SD`. The latter function approximates an integer by adding successive signed-digits^c. The *oct*-file `bin2SD.cc` implements a C++ version of `bin2SD`. The filter responses for the corresponding Butterworth and all-pass filters with 10-bit 2-signed-digit coefficients are shown in Figure 5.20. The response demonstrates a drawback of the normalised-scaled lattice filters: they are not *structurally loss-less* in the sense of Vaidyanathan et al. [116, 113] (see Appendix K.2). The normalised-scaled lattice does not preserve the all-pass characteristic when its coefficients are truncated.

^cParhi [73, Section 13.6.1, p.507] shows an algorithm that calculates the complete signed-digit representation. The Octave function `bin2SPT` and *oct*-file `bin2SPT.cc` implement this algorithm.

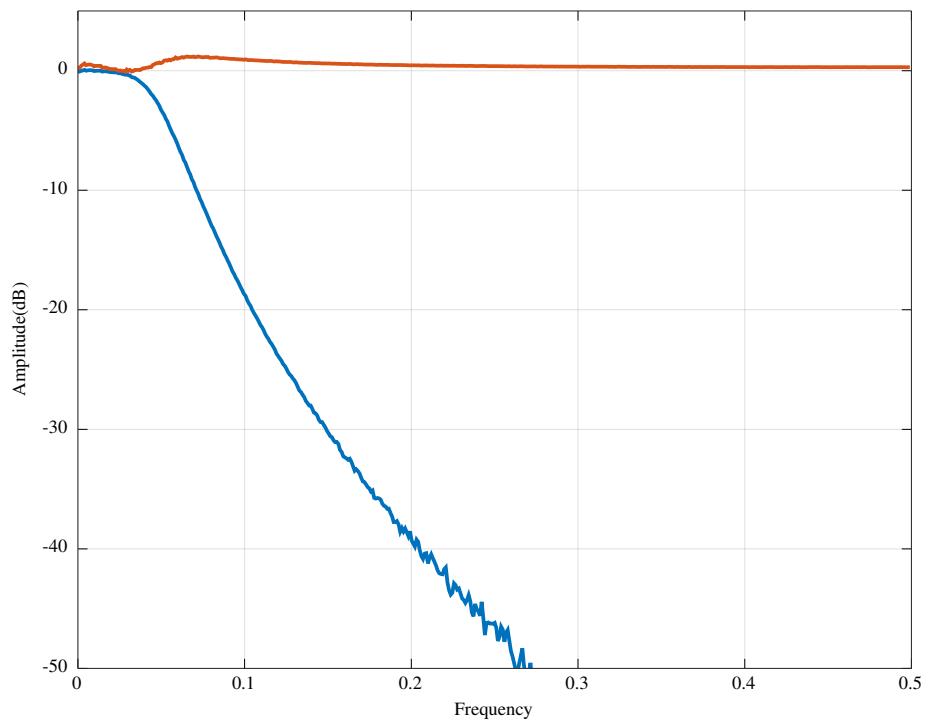

Figure 5.20: Frequency response of the 3rd order Butterworth filter implemented with a normalised-scaled lattice structure and 10-bit 2 signed-digit coefficients

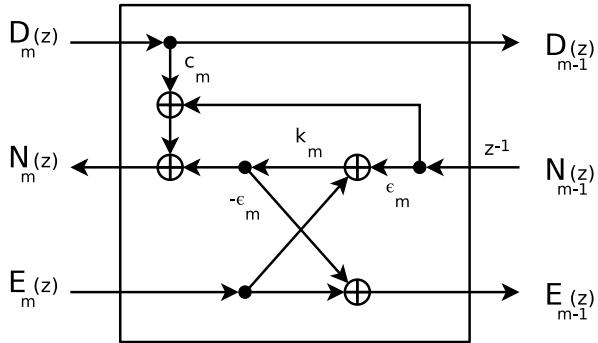

Figure 5.21: Transposed one multiplier lattice filter module

5.7.2 Round-off noise of the one multiplier lattice filter

Calculation of the one multiplier lattice filter round-off noise with the transposed signal flow graph

Figure 5.21 shows module m of $N, \dots, 1$ of the transposed graph of a one multiplier lattice filter. The transposed graph of the module gives

$$\begin{aligned} E_{m-1} &= -\epsilon_m^2 k_m z^{-1} N_{m-1} + (1 - k_m \epsilon_m) E_m \\ N_m &= (1 + \epsilon_m k_m) z^{-1} N_{m-1} + c_m D_m + k_m E_m \\ (1 + \epsilon_m k_m) z^{-1} N_{m-1} &= N_m - c_m D_m - k_m E_m \\ (1 + \epsilon_m k_m) E_{m-1} &= -k_m N_m + c_m k_m D_m + E_m \end{aligned}$$

Finally

$$\begin{bmatrix} z^{-1} N_{m-1}(z) \\ D_{m-1}(z) \\ E_{m-1}(z) \end{bmatrix} = \frac{1}{1 + \epsilon_m k_m} \begin{bmatrix} 1 & -c_m & -k_m \\ 0 & 1 + \epsilon_m k_m & 0 \\ -k_m & c_m k_m & 1 \end{bmatrix} \begin{bmatrix} N_m(z) \\ D_m(z) \\ E_m(z) \end{bmatrix}$$

The single-multiplier lattice basis functions, $\Lambda_i(z)$, are orthogonal but not orthonormal. The basis functions, $\Phi_i(z)$, of the normalised-scaled lattice are orthonormal so, for a unit-power white noise input, each node of the normalised-scaled lattice has unit-power. Equation 5.11 shows the expected power at each lattice node of the unscaled one multiplier lattice. Recall that this follows from the definition of the inner product of Schur polynomials and Parseval's equality:

$$\|g_i\|_2^2 = \frac{1}{2\pi i} \oint G(z) G_i(z^{-1}) \frac{dz}{z}$$

where $G_i(z)$ is the z -transform of g_i , the unit-impulse response from internal node i to the output. Similarly, for the scaled filter with unit-impulse response from the input to internal node i , $f_i(k)$, the ℓ_2 scaling rule gives

$$\|f_i\|^2 = \sum_{k=0}^{\infty} f_i^2(k) = 1$$

The noise gain calculation assumes that there is an equivalent white noise input at the i -th node of variance $q^2/12$ where q is the quantisation step size. The noise at the output is due to this node is $q \|g_i\|^2/12$. If the filter is not scaled then the unit impulse response from the input to internal node i is not unity. The filter is scaled by dividing coefficients on branches entering node i by $\|f_i\|$ and multiplying coefficients on branches leaving the i -th node by $\|f_i\|$. Therefore the output noise variance for scaled filters is

$$\sigma^2 = \frac{q^2}{12} \sum_i \|f_i\|^2 \|g_i\|^2$$

The Octave function *schurOneMlatticeFilter* implements this scaling.

The Octave script *butt3OneM_test.m* implements a 3rd order Butterworth filter with the single-multiplier lattice structure. Annotated results of the script follow.

The multiplier and sign coefficients are

```
k = -0.97432  0.92923 -0.53208
epsilon = -1   -1    -1
```

The scaling factors for each section are

```
p = 3.03862 0.34657 1.80947
```

The numerator polynomial expands in the orthonormal Schur basis, $\Phi_i(z)$, found above, as

```
c = 0.1005013 0.2986163 0.0101661 0.0028982
```

The scaled Butterworth filter noise gain with exact coefficients is

```
ng = 0.98228
```

and the scaled all-pass noise gain is

```
ngap = 5.0000
```

Using the 10-bit random test signal above, the estimated and measured round-off noise variance at the Butterworth output is

```
est_varyd = 0.16519  
varyd = 0.16571
```

and at the all-pass output the estimated and measured round-off noise variance is

```
est_varyapd = 0.50000  
varyapd = 0.49645
```

For the scaled filter, the signal at each internal unit delay storage element has standard deviation

```
stdxf = 131.32 129.47 127.97
```

Note that the noise gain for the low-pass filter is slightly smaller than for the normalised-scaled lattice filter.

Calculation of the one multiplier lattice filter round-off noise with a retimed state-variable description

The single-multiplier lattice round-off noise variance can also be determined from the state variable representation if the signal flow graph is slowed and retimed as shown in Figure 5.22. Each intermediate node is now associated with a state. The additional states alter the overall transfer function but the round-off noise gains are unchanged. The state-variable equations for this single-multiplier lattice example after slowing and re-timing are calculated in the Octave function *schurOneMlatticeRetimedNoiseGain*. The Octave function *schurOneMlatticeFilter* calculates the upper, Butterworth output, edge of Figure 5.4 in a single operation, ie: with a single large accumulator, and the lower, all-pass output, edge with separate truncated accumulations. On the other hand, the Octave function *svf* implements a general state-variable filter with truncated accumulations for each state and a wide accumulator for both the outputs. The round-off noise estimation in *schurOneMlatticeRetimedNoiseGain* illustrates that the retiming method of calculating noise gain is much more flexible than the transposed filter method. In addition, as noted in Section 5.7.1, the Schur basis is not truncated at the same time as the lattice coefficients but is still used to calculate the noise gain after truncation. Consequently, it is simpler to use the state-variable description to calculate the round-off noise of the one multiplier lattice with truncated coefficients.

The *schurOneMlatticeRetimedNoiseGain* function can calculate round-off noise gain for three different one multiplier lattice filter implementations by selecting the states included through the *filterStr* argument:

- For “**schur**” *schurOneMlatticeFilter* calculates the Butterworth output (the upper row of Figure 5.22) in a single wide accumulator and ignores the states on the top edge
- For “**ABCD**” *svf* calculates both the Butterworth output and the all-pass output in wide accumulators and ignores the states on both the top and bottom edges

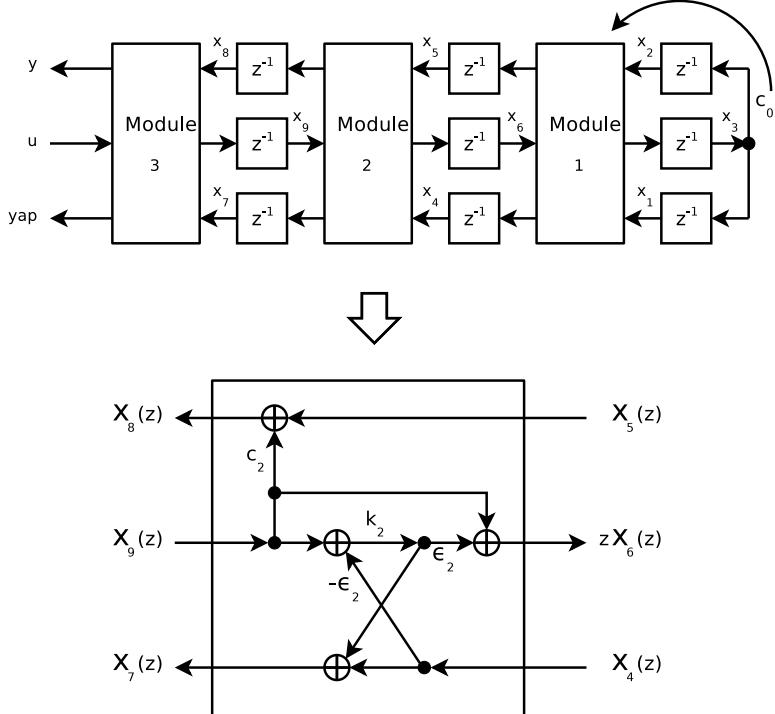

Figure 5.22: Slowed and retimed single-multiplier lattice for the 3rd order Butterworth example

In both these cases, states x_1 and x_2 in Figure 5.22 do not contribute to the round-off noise. (In the case of x_2 , c_0 is included in the calculation of state x_5).

The Octave script *butt3OneMSV_test.m* implements this state-variable description and calculates the round-off noise. The results of the script are shown in the following.

When filter type “schur” is selected the round-off noise gains for exact filter coefficients calculated with the Octave function *schurOneMlatticeRetimedNoiseGain* match those found with *schurOneMlatticeNoiseGain*.

When filter type “ABCD” is selected the Butterworth filter noise gain is $ng_{ABCD} = 0.75000$ and the all-pass noise gain is $ng_{ABCDap} = 3.0000$.

With exact coefficients, the globally optimised state-variable implementation has a noise gain of $ng_{opt} = 0.47049$ for the Butterworth filter and $ng_{optap} = 3.0000$ for the all-pass filter.

After truncating the k and c coefficients to 10 bit 3-signed-digits the Butterworth and all-pass noise gains were $ngf = 1.1019$ and $ngfap = 5.0000$ respectively. Note that the state scaling factors, p , are not truncated. With 10 bit 2 signed-digit coefficients (as used for the normalised-scaled lattice in Section 5.7.1) the passband response of the filter was unacceptable.

With rounding-to-nearest arithmetic truncation in the accumulator, the estimated and measured round-off noise variance of the one multiplier Schur lattice filter with 10-bit 3-signed-digit truncated coefficients are, for the Butterworth filter:

```
est_varyd = 0.17516
varyd = 0.17410
```

and for the allpass filter:

```
est_varyapd = 0.50000
varyapd = 0.49283
```

The standard deviations of the internal states of the filter are

```
stdxf = 137.06 129.04 127.82
```

Figure 5.23 shows the transfer function of the filter found by cross-correlation of the input and Butterworth and all-pass filter outputs when the filter is calculated as a Schur scaled one multiplier lattice with 10-bit 3-signed-digit truncated coefficients in the Octave function *schurOneMlatticeFilter*.

5.7.3 Frequency transformations and Schur normalised-scaled lattice filter round-off noise

Section 2.3 shows the frequency transformation of a state variable filter. Section 3.8 shows some results, given by *Mullis and Roberts* [21, Section III], concerning the noise gain of a frequency transformed state variable filter. *Koshita et al.* [147] point out that the normalised-scaled Schur lattice all-pass filter has controllability and observability Grammians $K = W = I$. It follows from Equation 3.4 that the frequency transformed filter constructed with the state variable implementation of that Schur normalised-scaled all-pass lattice filter has the same noise gain as the globally optimised implementation of the frequency transformed filter (see Section 3.5). Further, the state-transition matrix of the lattice all-pass frequency transformation filter is Hessenberg in form so the state-transition matrix of the frequency transformed filter has many zero entries. The Octave function `tfp2schurNSlattice2Abcd` implements the frequency transformation of a prototype filter as follows:

1. construct the state variable implementation, $\{\alpha, \beta, \gamma, \delta\}$, of the Schur normalised-scaled lattice filter corresponding to the all-pass frequency transformation, $F(z)$
2. construct the globally optimised state-variable implementation, $\{a, b, c, d\}$, of the low-pass filter prototype, $H(z)$
3. construct the state variable implementation, $\{A, B, C, D\}$, of the frequency transformed filter, $H(F(z))$

The Octave script `tfp2schurNSlattice2Abcd_test.m` exercises `tfp2schurNSlattice2Abcd` with the 5th order elliptic low-pass to multiple stop-band filter example of Section 2.4 shown in Figure 2.6. Table 5.1 shows the number of non-zero coefficients, the noise gain and the estimated noise variance in bits of the multiple band-stop filter implemented by `tfp2schurNSlattice2Abcd`, a globally optimised state variable filter, a Schur normalised-scaled lattice filter and a Schur one-multiplier lattice filter (neglecting the one-multiplier state scaling).

5.8 Examples of retiming Schur lattice filters

5.8.1 Retiming a 3-rd order lattice filter

Figure 5.24a shows a representation 3rd order lattice filter and Figure 5.24b shows the filter after retiming by moving the second filter delay to the upper and lower branches of the signal flow graph. The total delay in each loop of the signal flow graph is

	Non-zero coefficients	Noise gain	Noise variance(bits)
ABCD transformed	286	6.44	0.62
Globally optimised	961	6.44	0.62
Schur normalised-scaled lattice	180	18.88	1.66
Schur one-multiplier lattice	60	13.60	1.22

Table 5.1: Schur NS lattice frequency transformation round-off noise example : number of non-zero coefficients, noise gain and estimated output roundoff noise variances for a prototype 5th order elliptic low-pass filter transformed to a multiple band-stop filter.

Figure 5.24: Example of retiming a 3rd order lattice filter

unchanged so the transfer function of the filter is also unchanged. Retiming limits the maximum latency of each filter update calculation to the latency of two sections and changes the round-off noise performance of the filter^d. Appendix 5.6.3 derives the state variable description of the retimed one-multiplier Schur lattice filter.

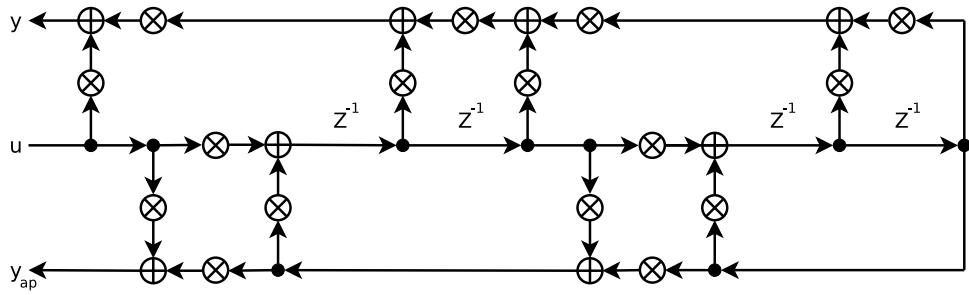

5.8.2 Retiming a 4-th order Schur normalised-scaled lattice filter

The normalised-scaled lattice filter of order N shown in Figure 5.7 has a delay-free path, or latency, of N adds and N multiplies to the tapped and all-pass outputs, y and y_{ap} respectively. Section 1.12.1 describes a procedure for inserting fractional delays in the signal flowgraph of the filter to reduce the length of the delay free path. The clock rate of the resulting filter is a multiple of the sample rate. Parhi [73, Chapter 4] discusses formal methods for retiming a signal flow graph. Figure 5.25a shows a simplified view of a normalised-scaled Schur lattice filter implementing a 4-th order transfer function with a denominator polynomial having coefficients only in z^{-2} . Figure 5.25b shows the example filter after redistributing the delay in each loop of the graph so that the total delay around that loop is unchanged. Each state update in the resulting filter has the form $pq + rs$. In this case the filter group delay is increased by 2 samples. In general, this retiming scheme increases the group delay by 1 sample for each second-order section.

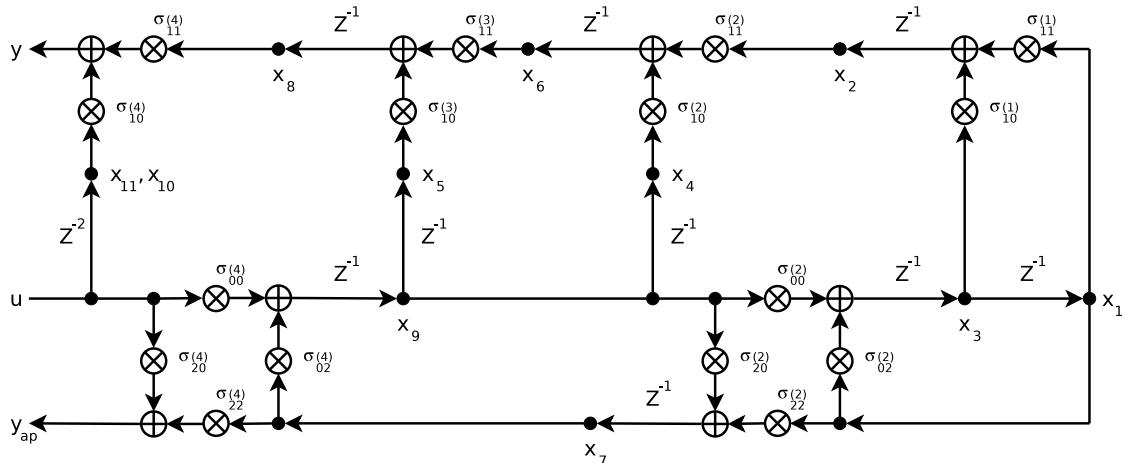

Following the notation of Figure 5.11, the state variable equations for the filter shown in Figure 5.25b are:

$$\begin{aligned}
 x_1(k+1) &= x_3(k) \\
 x_2(k+1) &= \sigma_{11}^{(1)}x_1(k) + \sigma_{10}^{(1)}x_3(k) \\
 x_3(k+1) &= \sigma_{02}^{(2)}x_1(k) + \sigma_{00}^{(2)}x_9(k) \\
 x_4(k+1) &= x_9(k) \\
 x_5(k+1) &= x_9(k) \\
 x_6(k+1) &= \sigma_{11}^{(2)}x_2(k) + \sigma_{10}^{(2)}x_4(k) \\
 x_7(k+1) &= \sigma_{22}^{(2)}x_1(k) + \sigma_{20}^{(2)}x_9(k)
 \end{aligned}$$

^dThe tapped output could be retimed by pipelining the arithmetic operations in a tree structure. The all-pass lattice ouput calculation is recursive and cannot be retimed in that way.

(a) In original form

(b) After retiming

Figure 5.25: Signal flow graph of a 4th order normalised-scaled Schur lattice filter with a denominator polynomial having coefficients only in z^{-2}

$$\begin{aligned}
 x_8(k+1) &= \sigma_{10}^{(4)}x_5(k) + \sigma_{11}^{(3)}x_6(k) \\
 x_9(k+1) &= \sigma_{02}^{(4)}x_7(k) + \sigma_{00}^{(4)}u(k) \\
 x_{10}(k+1) &= x_{11}(k) \\
 x_{11}(k+1) &= u(k) \\
 y(k) &= \sigma_{11}^{(4)}x_8(k) + \sigma_{10}^{(4)}x_{10}(k) \\
 y_{ap}(k) &= \sigma_{22}^{(4)}x_7(k) + \sigma_{20}^{(4)}u(k)
 \end{aligned}$$

The Octave script *schur_retimed_test.m* designs a 4-th order low-pass filter with cutoff frequency $0.05f_S$ and denominator coefficients in z^{-2} . The script minimises the amplitude response error with the Octave *fminunc* function. The barrier function of Tarczynski *et al.* [9] is added to the response error to constrain the locations of the roots of the denominator polynomial and ensure that the filter is stable. The barrier function is implemented in Octave function *WISEJ.m*. Figure 5.26 shows the simulated amplitude response of the retimed Schur lattice filter.

5.8.3 Retiming a 6th-order Schur one-multiplier lattice filter

Figure 5.27 shows the signal flow graph of a retimed 6th order one-multiplier Schur lattice filter with a denominator polynomial having coefficients only in z^{-2} . Both filter implementations have the same number of delays around the corresponding loops of their signal flow graphs. Retiming the filter reduces the latency in the calculation of the outputs and does not change the amplitude and group delay responses. If N is the filter order then the retimed filter has an additional $\frac{N}{2} - 1$ states. The Octave function *schurOneMR2lattice2Abcd*, exercised by the Octave script *schurOneMR2lattice2Abcd_test.m*, implements retiming of a one-multiplier Schur lattice filter with a denominator polynomial having coefficients in z^{-2} only.

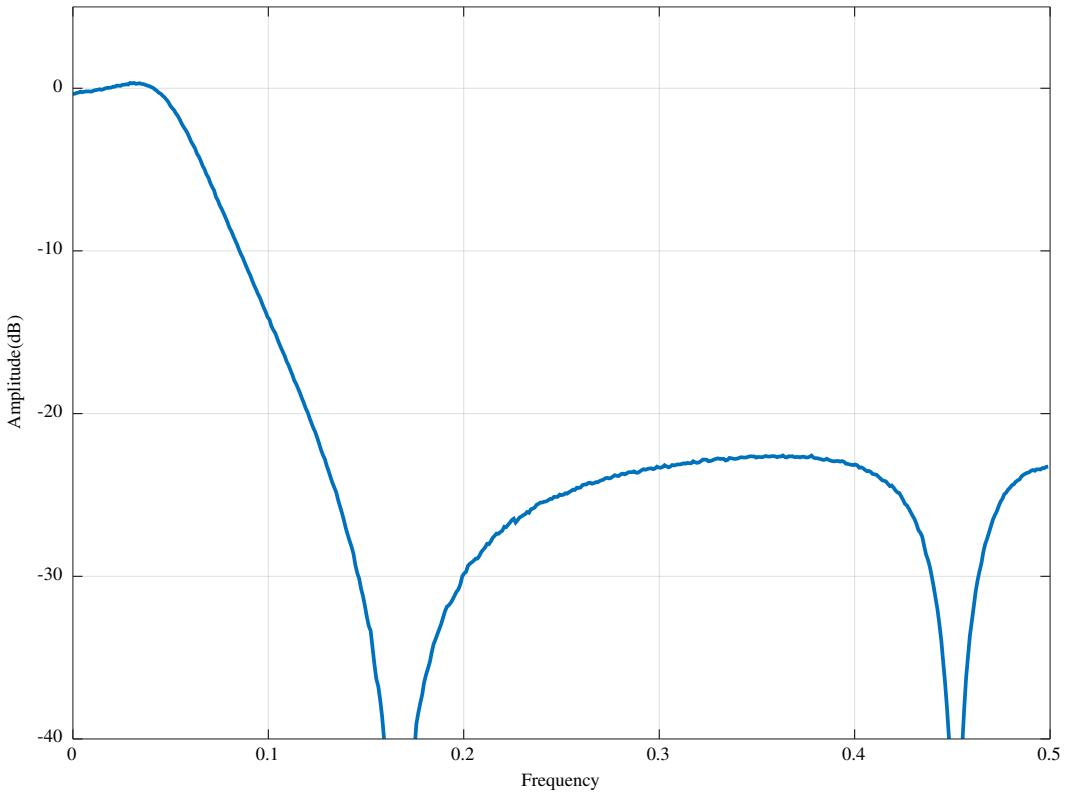

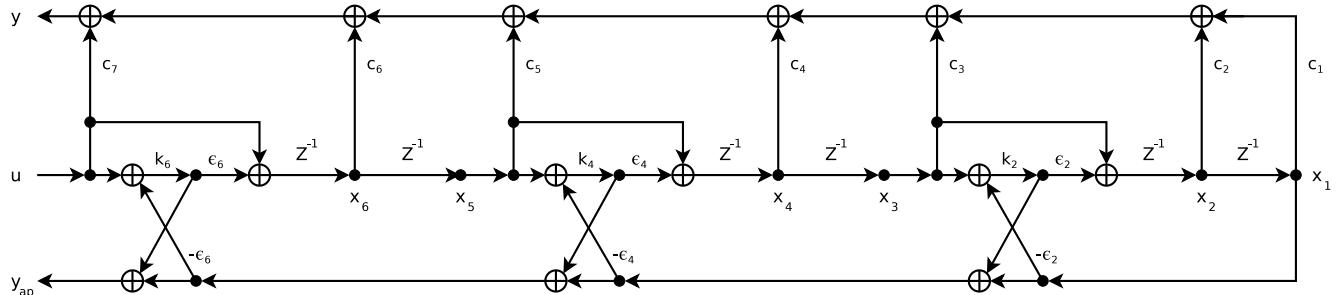

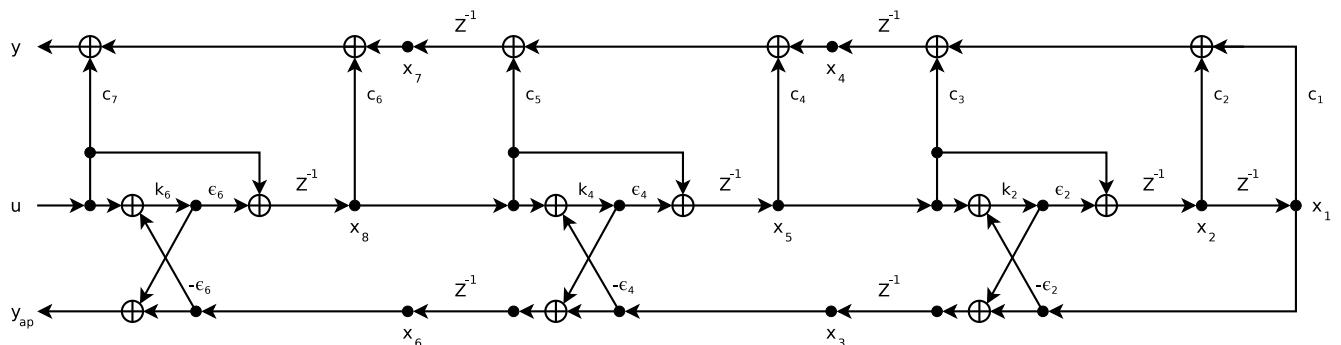

Figure 5.26: Simulated amplitude response of the retimed 4th order normalised-scaled Schur lattice filter

(a) Signal flow graph of a 6th order one-multiplier Schur lattice filter with a denominator polynomial having coefficients only in z^{-2}

(b) Signal flow graph of a 6th order one-multiplier Schur lattice filter with a denominator polynomial having coefficients only in z^{-2} after retiming

Figure 5.27: Original and retimed signal flow graphs of a 6th order one-multiplier Schur lattice filter with a denominator polynomial having coefficients only in z^{-2} . The number of delays around each loop of the signal flow graph is unchanged.

5.8.4 Frequency transformations of retimed Schur lattice filters

An implementation of a rational transfer function having denominator coefficients only in powers of z^{-2} can be retimed and pipelined so that the resulting filter is suitable for hardware implementation. This section gives an example of the effect of frequency transformations on such a filter transfer function. The Octave script *freq_trans_structure_test.m* designs an 8-th order low-pass filter prototype with a denominator polynomial having coefficients only in powers of z^{-2} . The script minimises the amplitude response error with the Octave *fminunc* function. The barrier function of Tarczynski *et al.* [9] is added to the response error to constrain the locations of the roots of the denominator polynomial and ensure that the filter is stable. The barrier function is implemented in Octave function *WISEJ.m*. The relative weights of the pass-band and stop-band response errors are 1 : 100. The transfer function numerator and denominator polynomials for the low-pass filter prototype are, respectively:

```
n = [ 0.0857526461, 0.2721065334, 0.5924693555, 0.8872367637, ...
      1.0183181186, 0.8872367931, 0.5924694628, 0.2721066332, ...
      0.0857528266 ];
dR = [ 1.0000000000, 0.0000000000, 2.0227725009, 0.0000000000, ...
      1.3779306177, 0.0000000000, 0.3584982390, 0.0000000000, ...
      0.0507148469 ];
```

Figure 5.28a shows the response of the low-pass prototype filter.

Figure 5.28b shows the response of a band-pass filter generated from the low-pass prototype filter with the following frequency transformation:

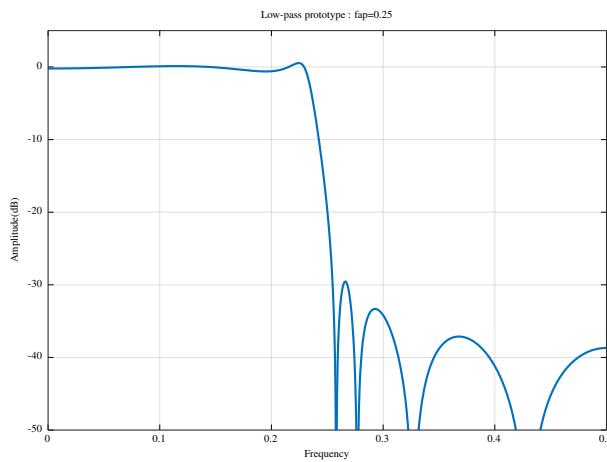

```
pA = phi2P([0.1 0.25])
pA = [ 1.0000e+00 -6.7508e-01 3.2492e-01 ]
```

The denominator polynomial of the resulting band-pass filter has coefficients in powers of z^{-1} .

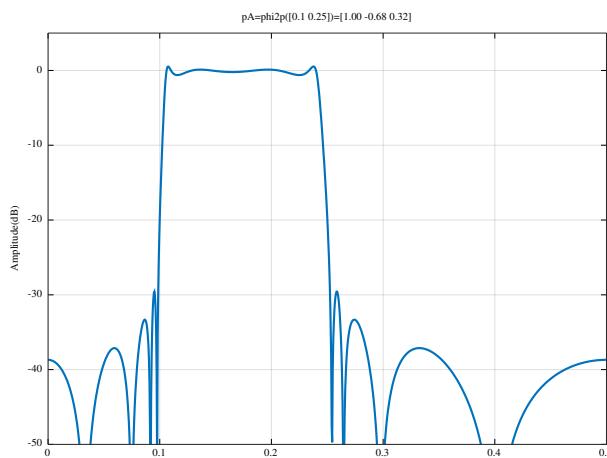

Figure 5.28c shows the response of a band-pass filter generated from the low-pass prototype filter with a frequency transformation that is symmetrical about $\frac{f_S}{4}$:

```
pB = phi2P([0.2 0.3])
pB = [ 1.0000e+00 0.0000e+00 5.0953e-01 ]
```

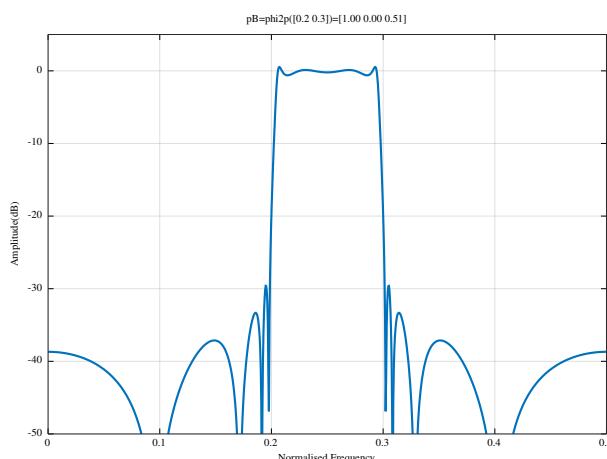

In this case, both the numerator and denominator polynomials of the resulting band-pass filter have coefficients only in powers of z^{-2} .

(a) Amplitude response of a low-pass filter prototype having denominator polynomial coefficients in z^{-2}

(b) Amplitude response of a band-pass filter with frequency transformation [0.1 0.25]

(c) Amplitude response of a band-pass filter with frequency transformation [0.2 0.3]

Figure 5.28: Frequency transformations of a low-pass filter prototype having denominator polynomial coefficients in powers of z^{-2} only

5.9 Summary

Given a transfer function $H(z) = N_N(z) / D_N(z)$ the design procedure for the normalised-scaled lattice filter is:

1. Compute the Schur polynomials from the denominator $D_N(z)$
2. Compute the parameters k_i for $i = N, N - 1, \dots, 1$
3. Expand the numerator $N_N(z)$ in the Schur polynomial basis by the polynomial expansion algorithm
4. Synthesise the filter by Equations 5.16, 5.17, 5.18, 5.19, 5.20 and 5.21

Given a transfer function $H(z) = N_N(z) / D_N(z)$ the design procedure for the one multiplier lattice filter is:

1. Compute the Schur polynomials from the denominator $D_N(z)$
2. Compute the parameters k_i for $i = N, N - 1, \dots, 1$
3. Find the k_i with greatest magnitude and recursively compute the sign parameters by Algorithm 5.2. Scale the Schur polynomial basis functions appropriately
4. Expand the numerator $N_N(z)$ in the Schur polynomial basis by the polynomial expansion algorithm
5. Synthesise the filter by Equations 5.8 and 5.9

The normalised-scaled lattice filter is not structurally passive, as is the one multiplier lattice filter, but the normalised-scaled lattice filter appears to be less sensitive to coefficient truncation than the one multiplier lattice filter. The normalised-scaled lattice filter is inherently scaled. The one multiplier lattice filter is not orthonormal and requires rather complex scaling.

Chapter 6

Orthogonal state variable filters

Chapter 5 described the Schur decomposition of an arbitrary rational filter transfer function into the normalised-scaled or one-multiplier tapped all-pass lattice representations with state covariance matrix $K = I$. The all-pass lattice filters so constructed are (in the terminology of *Roberts and Mullis*) *orthogonal* filters. In this chapter I review the method of *Roberts and Mullis* [129, Section 10.4] for decomposing an arbitrary transfer function into 2×2 block diagonal coordinate rotations that can be “*manipulated to achieve either high-speed, parallel computation using a sparsely connected array of processor modules or low-speed single processor realizations*”^a.

6.1 Definition of orthogonal state variable filters

If, for matrix O , $OO^T = I$, then $O \in \mathcal{O}$, the group of *orthogonal* matrixes. If U has *complex* elements and $UU^\dagger = I$ then $U \in \mathcal{U}$, where \dagger is the *conjugate transpose* matrix operator, and \mathcal{U} is the group of *unitary* matrixes. An all pass filter has magnitude response $|H(e^{i\theta})| = 1$ for all real θ . The $m \times m$ matrix transfer function $H(z)$ of m inputs and m outputs and complex elements is *all-pass* if $H(e^{i\theta})$ is unitary:

$$H(e^{i\theta}) \in \mathcal{U}(m) \quad \forall \text{ real } \theta$$

DEFINITION: A state variable filter $F = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$ belongs to the set of orthogonal, all-pass filters $\mathcal{F}(m, n)$ if

1. $AA^T + BB^T = I_{(n \times n)}$
2. $H(e^{i\theta}) = D + C(e^{i\theta}I - A)^{-1}B \in \mathcal{U}(m) \quad \forall \text{ real } \theta$

In addition, F belongs to the sub-set $\mathcal{F}_0(m, n)$ if it has the following equivalent properties:

1. $F \in \mathcal{F}_0(m, n)$
2. (A, B) is controllable
3. (A, C) is observable
4. $\det(\lambda I - A) = 0 \Rightarrow |\lambda| < 1$

As noted above, apart from F_L , each factor in the factored state variable description is an orthogonal matrix. For all-pass filters F_L is also orthogonal. More formally

$$\begin{aligned} F \in \mathcal{O}(m+n) &\Rightarrow F \in \mathcal{F}(m, n) \\ F \in \mathcal{F}_0(m, n) &\Rightarrow F \in \mathcal{O}(m+n) \end{aligned}$$

^aIn Appendix K.2, I review the method presented by *Vaidyanathan and Mitra* [116, 113] for decomposing an odd-order transfer function into the sum of two all-pass filters

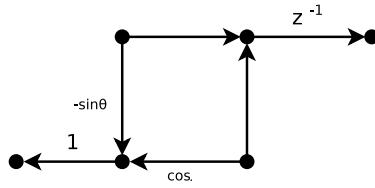

Figure 6.1: Lattice section

For any orthogonal matrix $F \in \mathcal{O}(N)$, there are N possible filters, one each in $\mathcal{F}(m, N - m)$, $1 \leq m \leq N$. The choice of m depends on how F is partitioned

$$F = \begin{bmatrix} A_{(N-m) \times (N-m)} & B_{(N-m) \times m} \\ C_{m \times (N-m)} & D_{m \times m} \end{bmatrix}$$

Note that transformations of the all-pass filter by $T \in \mathcal{O}(N)$,

$$\begin{aligned} F' &= \begin{bmatrix} A' & B' \\ C' & D' \end{bmatrix} \\ &= \left[\begin{array}{c|c} T^T AT & T^T B \\ \hline CT & D \end{array} \right] \\ &= \begin{bmatrix} T & 0 \\ 0 & I \end{bmatrix}^T \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} T & 0 \\ 0 & I \end{bmatrix} \end{aligned}$$

are also members of \mathcal{F} and that F' represents an alternative realisation of $H(z) = D + C(zI - A)^{-1}B$.

6.2 The Lattice Orthogonal All-Pass Filter Section

Figure 6.1 shows a possible realisation of the orthogonal lattice all-pass filter section. There are two inputs and two outputs. The filter matrix is given by

$$\begin{bmatrix} x' \\ y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} 0 & \cos \theta & \sin \theta \\ 1 & 0 & 0 \\ 0 & -\sin \theta & \cos \theta \end{bmatrix} \begin{bmatrix} x \\ u_1 \\ u_2 \end{bmatrix}$$

and the corresponding transfer function is

$$H(z) = \begin{bmatrix} z^{-1} \cos \theta & z^{-1} \sin \theta \\ -\sin \theta & \cos \theta \end{bmatrix}$$

6.3 Noise gain of orthogonal filters

For an orthogonal state variable structure, $K = I$, and the noise gain is

$$\begin{aligned} g_{orth} &= \frac{1}{n} \sum_{i=1}^n K_{ii} W_{ii} \\ &= \frac{1}{n} \sum_{i=1}^n \mu_i^2 \end{aligned}$$

where the μ_i^2 are the *second order modes* or eigenvalues of KW . For comparison, a globally optimised minimum noise filter with equal word-lengths has

$$\begin{aligned} g_{min} &= \frac{1}{n} \sum_{i=1}^n K_{ii} W_{ii} \\ &= \left[\frac{1}{n} \sum_{i=1}^n \mu_i \right]^2 \end{aligned}$$

Thus the difference between g_{orth} and g_{min} is the difference between a second moment and the square of a first moment, which is the variance. The two are only equal if the μ_i are all equal. Recall that the second order modes of the globally optimised filter are invariant under a frequency transformation.

6.4 Realisation of arbitrary filters from orthogonal sub-filters

Let $G(z)$ be the transfer function for an order n filter with 1 input and 1 output. Suppose

$$G = \begin{bmatrix} A & B \\ C_1 & D_1 \end{bmatrix}$$

is an orthogonal filter implementation with

$$K = AA^T + BB^T = I$$

The first n rows of G are orthonormal, but have dimension $n + 1$ so there exist C and D for which

$$F = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \in \mathcal{O}(n+1)$$

is orthonormal. The Schur decomposition of G produces an all-pass filter corresponding to F . The conversion from F to G can be found from

$$\begin{aligned} G &= \begin{bmatrix} A & B \\ C_1 & D_1 \end{bmatrix} F^T F \\ &= \begin{bmatrix} I & 0 \\ C_1 A^T + D_1 B^T & C_1 C^T + D_1 D^T \end{bmatrix} F \\ &= G_0 F \end{aligned}$$

where

$$\begin{aligned} [\Gamma \ \delta] &= [C_1 \ D_1] F^T \\ G_0 &= \begin{bmatrix} I & 0 \\ \Gamma & \delta \end{bmatrix} \end{aligned}$$

G_0 can be simplified by finding the transformation

$$T = \begin{bmatrix} T_0 & 0 \\ 0 & 1 \end{bmatrix} \in \mathcal{O}(n+1)$$

so that

$$\Gamma T_0 = [0 \ \gamma]$$

where γ is a scalar. T_0 can be found as the product of a series of rotations (each of which are members of $\mathcal{O}(n)$) that zero out the leading elements of Γ

$$[\gamma_i \ \gamma_{i+1}] \begin{bmatrix} \cos \theta_i & \sin \theta_i \\ -\sin \theta_i & \cos \theta_i \end{bmatrix} = [0 \ \gamma'_{i+1}]$$

where θ_i is given by

$$\tan \theta_i = \frac{\gamma_i}{\gamma_{i+1}}$$

Now transform G by T

$$\begin{aligned} G' &= T^{-1} GT \\ &= T^{-1} (G_0 F) T \\ &= (T^{-1} G_0 T) (T^{-1} F T) \\ &= G'_0 F' \end{aligned}$$

where

$$G'_0 = \begin{bmatrix} I & 0 & 0 \\ 0 & 1 & 0 \\ 0 & \gamma & \delta \end{bmatrix}$$

In other words, $F' \in \mathcal{F}(2, n-1)$ is a two-input, two-output all-pass filter and one of the all-pass outputs of F' becomes a state of $G(z)$. Figure 6.2 is a representation of the corresponding implementation of $G(z)$ (see [129, Figure 10.4.5]).

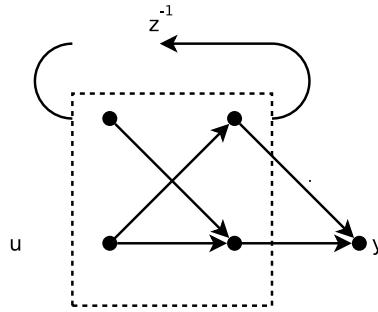

Figure 6.2: Signal flow graph of an arbitrary transfer function constructed from a two-input two-output all-pass filter

Roberts and Mullis [129, pp. 460-461] describe the following procedure for factoring a two-input, two-output all-pass filter, F , into the product of 2×2 block diagonal coordinate rotations of the form

$$\begin{bmatrix} T_1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \in \mathcal{O}(n+1)$$

that preserve G'_0 ^b:

1. Construct a series of similarity transformations that zero the elements of F which are more than 2 sub-diagonals below the main diagonal. For example, with $G(z)$ of order $n = 5$ so that $F \in \mathcal{O}(6)$:

$$F' = \begin{bmatrix} X & X & X & X & X & X \\ X & X & X & X & X & X \\ X & X & X & X & X & X \\ 0_6 & X & X & X & X & X \\ 0_4 & 0_5 & X & X & X & X \\ 0_1 & 0_2 & 0_3 & X & X & X \end{bmatrix} = T_6^T T_5^T T_4^T T_3^T T_2^T T_1^T F T_1 T_2 T_3 T_4 T_5 T_6$$

The indexes on the sub-diagonal zeros indicate the order of construction. The transformations T_i are constructed in the same manner as those that zero the leftmost elements of Γ . In the example:

$$\begin{aligned} & \begin{bmatrix} I_{4 \times 4} & 0 & 0 \\ 0 & \cos \theta & \sin \theta \\ 0 & -\sin \theta & \cos \theta \end{bmatrix}^T \begin{bmatrix} X & X & X & X & X & X \\ X & X & X & X & X & X \\ X & X & X & X & X & X \\ F_{4,1} & X & X & X & X & X \\ F_{5,1} & F_{5,2} & X & X & X & X \\ F_{6,1} & F_{6,2} & F_{6,3} & X & X & X \end{bmatrix} \begin{bmatrix} I_{4 \times 4} & 0 & 0 \\ 0 & \cos \theta & \sin \theta \\ 0 & -\sin \theta & \cos \theta \end{bmatrix} \\ &= \begin{bmatrix} X & X & X & X & X & X \\ X & X & X & X & X & X \\ X & X & X & X & X & X \\ F'_{4,1} & X & X & X & X & X \\ F'_{5,1} & F'_{5,2} & X & X & X & X \\ 0 & F'_{6,2} & F'_{6,3} & X & X & X \end{bmatrix} \end{aligned}$$

2. Factor F' with $q = 2n - 1$ coordinate rotations that zero the sub-diagonal elements

$$F'' = F' F_1 \cdots F_q$$

These are *not* similarity transformations. In fact, F'' will be diagonal with elements $\pm 1^c$. The diagonal elements can be included in the rotations so that:

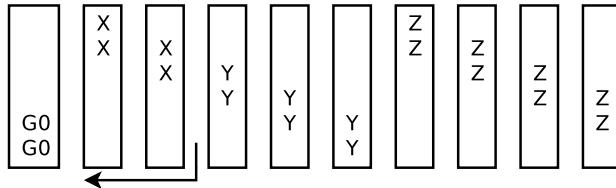

$$F' = F_q^T \cdots F_1^T$$

For example:

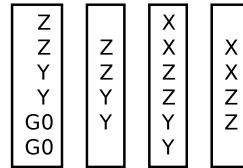

$$F'' = \begin{bmatrix} X & X & X & X & X & X \\ 0_9 & X & X & X & X & X \\ 0_4 & 0_8 & X & X & X & X \\ 0 & 0_3 & 0_7 & X & X & X \\ 0 & 0 & 0_2 & 0_6 & X & X \\ 0 & 0 & 0 & 0_1 & 0_5 & X \end{bmatrix} = F' F_1 F_2 F_3 F_4 F_5 F_6 F_7 F_8 F_9$$

^bThis procedure is known as the *upper Hessenberg reduction* [38, Section 7.4.2].

^cThis is a consequence of F'' being upper-triangular and $F'' \in \mathcal{O}(n+1)$.

(a) Orthogonal filter as a depth-10 pipeline with a single rotation element

(b) Orthogonal filter as a depth-4 pipeline

Figure 6.3: Orthogonal structures for a 5-th order filter

This realisation of $G(z)$ as a tapped lattice filter requires, as a starting point, an orthogonal state variable representation of $G(z)$ with $K = I$. The *singular value decomposition* [38, Theorem 2.5.2] provides the required similarity transform^d. Alternatively, the Schur decomposition of a transfer function (reviewed in Chapter 5, based on Parhi [73, Chapter 12]) realises an orthogonal lattice filter without requiring the calculation of K to find an initial similarity transformation^e. In practice, for larger filters, I have found that the Schur decomposition is more accurate.

The Octave function *orthogonaliseTF* returns the orthogonal decomposition of a rational polynomial transfer function. In the default configuration, *orthogonaliseTF* uses the Schur decomposition of the transfer function to find an orthogonal state transition matrix, A , and then finds the 2×2 block diagonal rotation matrixes in the orthogonal decomposition of the filter. As an example, the Octave script *orthogonaliseTF_test.m* finds the orthogonal decomposition of a 9th order elliptic low-pass filter with cutoff frequency $0.05f_S$. The orthogonal decomposition of the filter contains 17 non-trivial 2×2 block diagonal rotation matrixes. The noise gain of the orthogonal filter is 2.83. The noise gain of the corresponding minimum noise state variable filter is 1.64.

6.4.1 An example of structural variations

The decomposition of the filter transfer function into 2×2 block diagonal coordinate rotations permits straightforward modification of the filter factorisation. For example, suppose we design a 5-th order filter with the structure shown in Figure 6.3a. The 2×2 rotation matrixes on the diagonals are represented by the letters across two rows. All other elements are either 0 or, on the diagonal, 1. The structure shown in Figure 6.3a uses a single rotation time multiplexed across 9 matrixes (plus G'_0 , although that matrix is not orthogonal). The orthogonal matrixes above the arrow in Figure 6.3a can be combined into a single similarity transform, T , and applied to G_0F to form a new filter factorisation:

$$F' = T^{-1}FT$$

This is equivalent to a circular shift of the order of the orthogonal factor matrixes. Also, the individual factors commute if the 2×2 sub-matrixes on the diagonal have no common rows. Hence the filter matrix can be compacted as shown in Figure 6.3b, which represents a sequence of 2, 3, 2, 2 rotation elements in a depth-4 pipeline.

Roberts and Mullis [129, pp. 462-467] show other examples of orthogonal filter factorisation.

^dThe SVD of K gives $U^T KV = \text{diag}(\sigma_1, \dots, \sigma_n)$ where U and V are orthogonal $n \times n$ matrixes (ie: $U^T U = I$)

^eIn fact the Schur decomposition of the transfer function is equivalent to the orthogonal decomposition of the state transition matrix presented here.

Chapter 7

Feedforward and feedback of state quantisation error in state variable filters

Chapter 3 reviewed the optimisation of a state variable digital filter for minimum roundoff noise. The resulting filter has $\mathcal{O}(N^2)$ non-zero coefficients. Section 4 showed how a filter could be implemented as a cascade of second-order sections with section optimal roundoff noise performance. Chapters 5 and 6 reviewed the design of lattice filters with good roundoff noise performance and low coefficient sensitivity. An alternative technique for reducing the roundoff noise in the filter output is the feedback of the state quantisation error [47, 161, 30] in order to improve the roundoff noise performance of the filter with a small increase in complexity. *Mullis and Roberts* [23] show that complete or “optimal” error feedback is equivalent to increasing the word-lengths of the coefficients and state registers in the “usual” state variable filter without feedback. They point out that sub-optimal error feedback, that is choosing the registers that receive feedback and choosing coefficients that are a power-of-2, may provide improved noise performance with reduced complexity. Overflow oscillations and coefficient sensitivity must be considered on a case-by-case basis. *Li and Gevers* show that the “delta” operator method, where the usual time-shift operator, z , is replaced by $\delta = \frac{z-1}{\Delta}$ is a special case of the residue feed back method of *Williamson* [30]. *Lu and Hinamoto* [161] describe use of SQP-Relaxation non-linear optimisation to find the near-optimal signed-digit coefficients of a diagonal feedback matrix. Here I follow the paper by *Williamson* [30].

7.1 Problem formulation

Figure 7.1 [161, Figure 2] shows a block diagram of a state variable digital filter with feedback and feed-forward of the state quantisation error e . The state variable quantiser is Q , the feedback error transfer function is δ and the feed-forward error transfer function is η . As shown in Section 1.5 the unquantised state variable equations are

$$\begin{aligned}x(k+1) &= Ax(k) + Bu(k) \\y(k) &= Cx(k) + Du(k)\end{aligned}$$

In his treatment *Williamson* [30] states that “the coefficients $\{A, B, C, D\}$, while not necessarily less than 1 in magnitude, are assumed to have an exact fractional B_0 bit representation. The filter states $\tilde{x}(k)$ and the ouptut $y(k)$ all have a fractional $B + B_0$ bit representation and the input $u(k)$ is a B bit fraction. The quantiser $Q[\tilde{x}(k)]$ rounds the $B + B_0$ fraction $\tilde{x}(k)$ to B bits after the arithmetic operations are complete. Fixed point arithmetic is implemented using a two’s complement representation (where the sign bit is not counted)”. The *roundoff residue*, $e(k)$, is a $B + B_0$ bit fraction having zero in the most significant B bits:

$$e(k) = \tilde{x}(k) - Q[\tilde{x}(k)]$$

The roundoff residue sequence, $e(k)$, is modelled as a zero-mean noise process with covariance

$$\begin{aligned}\sigma_e &= E\{e(k)e^T(k)\} \\&= \frac{q^2}{12}I\end{aligned}$$

where $q = 2^{-B}$. When the state variables are quantised, the state variable equations for the error feedback/feed-forward filter of Figure 7.1 are

$$\tilde{x}(k+1) = AQ[\tilde{x}(k)] + Bu(k) + \delta e(k)$$

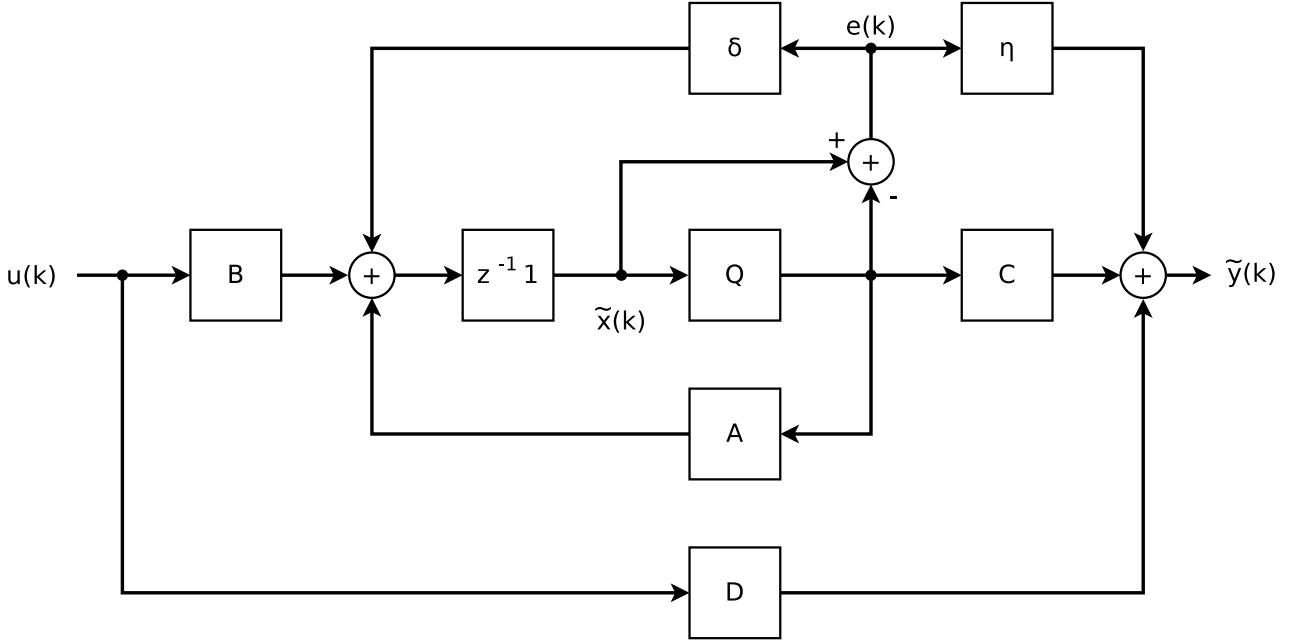

Figure 7.1: Error feedback and feed-forward in state variable digital filters. (Lu and Hinamoto [161, Figure 2])

$$\tilde{y}(k) = CQ[\tilde{x}(k)] + Du(k) + \eta e(k)$$

The round off noise for the filter is

$$\begin{aligned}\Delta x(k+1) &= A\Delta x(k) + (A - \delta)e(k) \\ \Delta y(k) &= C\Delta x(k) + (C - \eta)e(k)\end{aligned}$$

where $\Delta x(k) = \tilde{x}(k) - x(k)$ and $\Delta y(k) = \tilde{y}(k) - y(k)$. As shown in Section 1.9, the frequency domain transfer function from the state quantisation error to the output roundoff noise is:

$$\Delta H(z) = C(zI - A)^{-1}(A - \delta) + (C - \eta)$$

Section 3.3.3 shows that the probability of overflow can be minimised by appropriate l_2 -norm scaling of the state variables. If the input signal, $u(k)$, is zero-mean and unit variance, then the steady-state covariance of the state variables is, since $\tilde{x}(k)$ and $e(k)$ are uncorrelated

$$K = AKA^T + BB^T + q^2(A - \delta)(A - \delta)^T$$

If $q^2 \ll 1$ then

$$K \approx AKA^T + BB^T$$

For optimum l_2 -norm scaling $\text{diag}\{K\} = I$. As shown in Section 1.11, for $\Delta y(0) = 0$, the output roundoff noise error is

$$\Delta y(k) = \sum_{l=0}^{k-1} CA^l(A - \delta)e(k - m - 1) + (C - \eta)e(k)$$

As shown in Section 3.4, the output roundoff noise variance due to truncation of each state is $\sigma_e^2 \sigma^2$, where

$$\begin{aligned}\sigma^2 &= \text{trace} \left\{ (A - \delta)(A - \delta)^T W + (C - \eta)(C - \eta)^T \right\} \\ W &= AWA^T + CCT\end{aligned}$$

Williamson considers the noise minimisation problem of finding a realisation $\{A, B, C, D\}$ of $H(z)$ and integer-valued feedback gains $\{\delta, \eta\}$ such that the output noise gain, g , is minimised, subject to the state scaling constraint, $\text{diag}\{K\} = I$.

Given an initial realisation, $\{A_0, B_0, C_0, D\}$, of $H(z)$, Williamson [30, Section III] defines the *residue matrix* as

$$P_0 = (I - A)^T W_0 + W_0(I - A)$$

where

$$W_0 = A_0 W_0 A_0^T + C_0 C_0^T$$

He shows that the eigenvalues, $\{\mu_i^2\}$ of $K_0 W_0$, and $\{\rho_i^2\}$ of $K_0 P_0$, are invariant under a similarity transformation, T , and are positive. In Section 6.3, the eigenvalues $\{\mu_i^2\}$ are referred to as the *second-order modes* of $H(z)$. Williamson calls $\{\rho_i^2\}$ the *residue modes*. Further, he calls a realisation $\{A_0, B_0, C_0, D\}$ *input balanced* if $K_0 = I$ and $W_0 = M^2 = \text{diag}\{\mu_1^2, \dots, \mu_N^2\}$, where N is the order of $H(z)$ ^a. An input balanced structure can be transformed to an *internally balanced* structure with $K_1 = W_1 = M$ by means of the similarity transformation $T_1 = M^{-\frac{1}{2}}$.

7.2 Minimisation of round-off noise with $\delta = I$ and $\eta = 0$

Williamson [30, Section V] considers the “problem of finding the optimal transformation, T , and the optimal integer residue feedback matrixes δ_T and η_T , which together minimise the output round-off noise”. He proves the theorem shown as Algorithm 7.1 for the suboptimal case for a low-pass narrow-band filter in which $\delta_T = I$ and $\eta_T = 0$. (For a high-pass narrow-band filter $\delta_T = -I$). If $\delta_T = 0$ and $\eta_T = 0$ then the minimum noise gain is

$$g_M = \frac{\sum_{k=1}^N \mu_k}{\sqrt{N}}$$

Hence, error feedback reduces the noise gain only if the sum of the residue modes is less than the sum of the second-order modes.

Algorithm 7.1 Minimisation of round off noise in error feedback/feedforward state variable filters.

(See Williamson [30, Theorem 5.2]).

Let M define the second-order modes of a stable N th order filter, $H(z)$, with an input-balanced realisation, $\{A_0, B_0, C_0, D\}$. Consider the finite word length implementation $\{A_T = T^{-1}A_0T, B_T = T^{-1}B_0, C_T = T^TC_0, D\}$. Then subject to the l_2 -norm scaling constraint, the identity state residue correction, $\delta_T = I$, and the zero output residue correction, $\eta_T = 0$, the minimum noise filter is defined by

$$\begin{aligned} T &= R_1 \Pi R_0^T \\ \Pi &= \text{diag}\{\pi_1, \dots, \pi_N\} \end{aligned}$$

where

$$\pi_m^2 = \frac{1}{\rho_m} \frac{\sum_{k=1}^N \rho_k}{N}$$

and for unitary matrixes R_0 and R_1

$$\begin{aligned} \text{diag}\{R_0 \Pi^{-1} R_0^T\} &= I \\ R_1^T P_0 R_1 &\text{ is diagonal} \end{aligned}$$

where

$$P_0 = (I - A_0)^T M^2 + M^2 (I - A_0)$$

The residue modes $\{\rho_k\}$ are the square roots of the eigenvalues of P_0 . The corresponding minimum noise gain, g_I is

$$g_I = \frac{\sum_{k=1}^N \rho_k}{\sqrt{N}}$$

The Octave script *error_feedback_test.m* attempts to reproduce Williamson’s Example 6.3. This example considers error feedback for the 6th order filter given by $H(z) = \frac{q(z)}{p(z)}$ where

```
q=[0.0047079 -0.0251014 0.0584417 -0.0760820 0.0584417 -0.0251014 0.0047079];
p=[1 -5.6526064 13.3817570 -16.9792460 12.1764710 -4.6789191 0.7525573];
```

I found different values for the second order modes. I found that the optimum noise gain was 1.333 and the noise gain for an orthogonal filter was 2.086 whereas Williamson reports a noise gain of $g_M^2 = 5.8272$ in the latter case. I found the following values for the residue modes:

^aIf $K = I$, then the filter is *orthogonal*. See Part 6. An SVD transformation of the corresponding W matrix gives the input balanced structure.

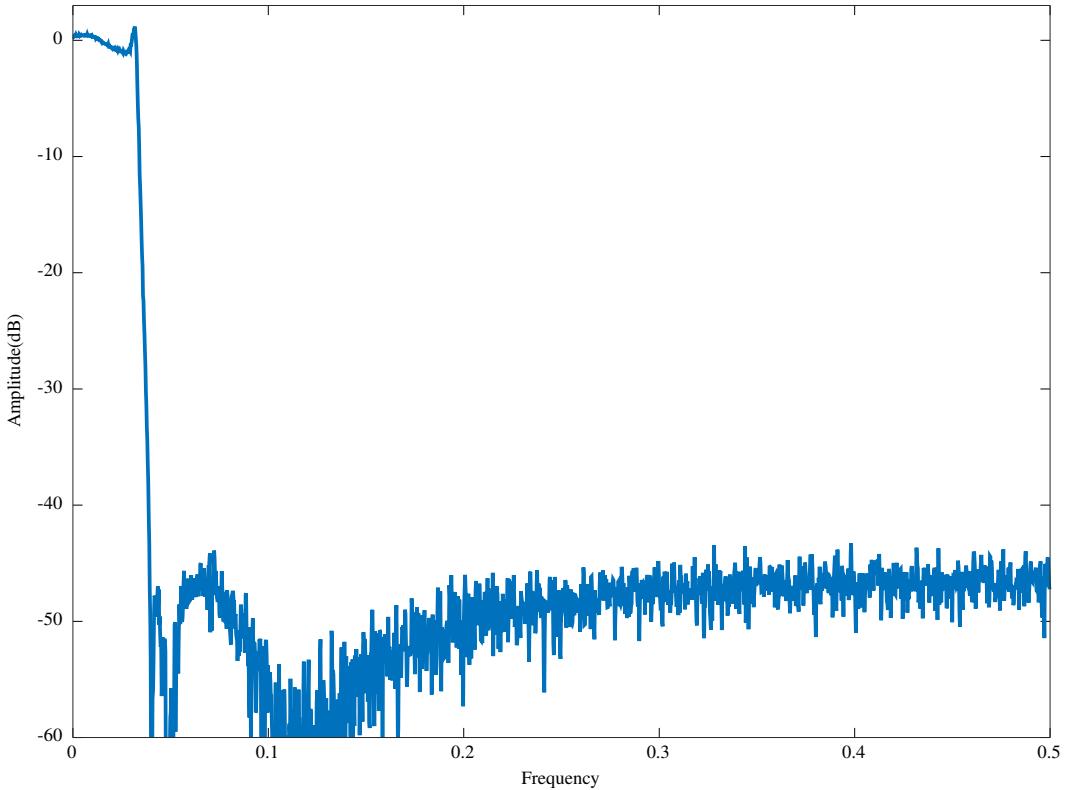

Figure 7.2: Simulated response of a 6-th order filter with 8 bit coefficients and a 2 bit mantissa (for error feedback) in the state variables. (After Williamson [30, Example 6.3]).

```
rho = [ 0.268561 0.141649 0.127042 0.058299 0.021251 0.005512]
```

and a noise gain of $g_I = 0.254$. The error-feedback filter was simulated with 8 bit coefficients by adding 2 bits to the state storage in the Octave function *svf.m* (as the mantissa, to the right of the binary point). The estimated output roundoff noise is 0.323 bits. The measured output roundoff noise is 0.308 bits. The output round-off noise is dominated by the noise due to the rounding of the output, $y(k)$: $\frac{1}{\sqrt{12}} = 0.2887$ bits. The simulated response is shown in Figure 7.2.

Part II

Constrained optimisation of the IIR filter frequency response

Chapter 8

IIR filter design using Sequential Quadratic Programming with the transfer function defined by pole and zero locations

The transfer function or response of an IIR digital filter is usually written in the z -transform domain similarly to

$$H(z) = \frac{b(z)}{a(z)} = \frac{\sum_{l=0}^m b_l z^{-l}}{1 + \sum_{l=1}^n a_l z^{-l}} \quad (8.1)$$

Where $0 \leq m \leq n$. Poles at zero may be added to ensure that the filter is *causal*. For a causal filter, the output of the filter only depends inputs from the past. When z is interpreted as a single sample delay this means that the order of the numerator is less than or equal to the order of the denominator. A non-causal filter can be used to process signals off-line. Alternatively, the non-causal filter can be decomposed by polynomial division into a parallel and cascade combination. A *stable* filter has all the roots of the denominator polynomial inside the unit circle in the z -plane. A *minimum phase* filter has both poles and zeros inside the unit circle in the z -plane so that the inverse filter is also stable.

Equation 1 minimises the error in the *complex* response (amplitude and phase). In contrast, in the following the weighted amplitude and group-delay response squared-error is minimised and filter stability is obtained by constraints on the pole location. The *sequential quadratic programming* (SQP) optimisation method linearises the response error at the current estimate of the solution and solves the corresponding constrained quadratic programming problem to find a new estimate that minimises the linearised error. The procedure stops at a *local* minimum of the error surface. Unfortunately, the filter design error surface usually has many, many local minima. Achieving success in finding a good solution (for which the error value at the local minimum is close to the *global* minimum) depends on the initial solution and the formulation and weighting of the error function^a.

8.1 Problem Statement

The magnitude and group delay responses of an IIR digital filter are optimised in terms of a coefficient vector containing the gain-zero-pole definition of the transfer function

$$x = [K, R_{0,1}, \dots, R_{0,U}, R_{p,1}, \dots, R_{p,V}, r_{0,1}, \dots, r_{0,\frac{M}{2}}, \phi_{0,1}, \dots, \phi_{0,\frac{M}{2}}, r_{p,1}, \dots, r_{p,\frac{Q}{2}}, \phi_{p,1}, \dots, \phi_{p,\frac{Q}{2}}] \quad (8.2)$$

This vector represents the poles and zeros of a filter with gain factor K , the radiiuses of U real zeros and V real poles and the radiiuses and angle of $\frac{M}{2}$ pairs of conjugate zeros and $\frac{Q}{2}$ pairs of conjugate poles. Note that for decimation factor, R , the poles are in fact on the z^R plane and each pole in x corresponds to R poles on the z plane. Appendix E shows the amplitude, phase and group delay responses and their gradients in terms of the coefficient vector.

^aAn alternative to Equation 1 is to linearise the cost function, \mathcal{E}_H , by:

$$\hat{\mathcal{E}}_H = \sum_{j=1}^{NB} \int_{f_{l,j}}^{f_{u,j}} \frac{W_j(f)}{|\hat{D}(f)|^2} |N(f) - D(f) H_d(f)|^2 df$$

where \hat{D} is the previous estimate of D . See, for example, Dumitrescu and Niemistö [17]

The weighted squared-magnitude of the response error, \mathcal{E}_A , is:

$$\mathcal{E}_A(x) = \sum_{j=1}^{NB} \int_{f_{l,j}}^{f_{u,j}} W_{Aj}(f) [A(x, f) - A_D(x, f)]^2 df$$

where NB is the number of frequency bands, $f_{u,j}$ the upper and $f_{l,j}$ the lower frequency band edges, W_{Aj} the weighting function for each frequency band, and A is the actual and A_D the desired magnitude response. The weighted time delay error, \mathcal{E}_T , is similarly expressed in terms of W_{Tj} the weighting function for each frequency band, the actual group delay response, T , and the desired group delay response, T_D .

The optimal filter design minimises the total weighted squared response error, $\mathcal{E} = \mathcal{E}_A + \mathcal{E}_T$, subject to constraints $g_i(x) \geq 0$ where $x \in \mathcal{D} \subset \mathbb{R}_N$ and the filter is stable for $x \in \mathcal{D}$. The method of *Lagrange multipliers* minimises the *Lagrangian* function:

$$\mathcal{L}(x, \lambda_i) = \mathcal{E}(x) - \sum_{i \in \mathcal{A}(x)} \lambda_i g_i(x)$$

where $\mathcal{A}(x)$ represents the set of active constraints at x and λ_i are the Lagrange multipliers (or *dual variables*) for those constraints. The *Karush-Kuhn-Tucker* conditions for the minimum are:

$$\nabla_x \left\{ \mathcal{E}(x) - \sum_{i \in \mathcal{A}(x)} \lambda_i g_i(x) \right\} = 0 \quad (8.3)$$

$$g_i(x) \geq 0 \quad (8.4)$$

$$\lambda_i \geq 0 \quad (8.5)$$

$$\langle \lambda_i, g_i(x) \rangle = 0 \quad (8.6)$$

The gradient of the magnitude error is:

$$\nabla_x \mathcal{E}_A(x) = \sum_{j=1}^{NB} 2 \int_{f_{l,j}}^{f_{u,j}} W_{Aj}(f) [A(x, f) - A_D(x, f)] \nabla_x A(x, f) df$$

The gradient of the delay error is similar.

The literature often refers to the *dual* problem, finding the greatest lower bound of the dual function:

$$\Lambda(\lambda_i) = \inf_{x \in \mathcal{D}} \left\{ \mathcal{E}(x) - \sum_{i \in \mathcal{A}(x)} \lambda_i g_i(x) \right\}$$

8.1.1 Solution of the constrained quasi-Newton optimisation problem

Express the *Karush-Kuhn-Tucker* conditions (Equations 8.3 and 8.4) at x^k in terms of a linearised version of the gradient of the error and linearised constraints (see Appendix I.1):

$$\begin{aligned} \nabla_x \mathcal{E}(x^k) + \nabla_x^2 \mathcal{E}(x^k)(x - x^k) - \sum_{i \in \mathcal{A}(x)} \lambda_i \nabla_x g_i(x^k) &= 0 \\ g_i(x^k) + \nabla_x g_i(x^k)(x - x^k) &\geq 0 \end{aligned} \quad (8.7)$$

where the Hessian of the squared-magnitude response error, \mathcal{E}_A , is:

$$\nabla_x^2 \mathcal{E}_A(x) = \sum_{j=1}^{NB} 2 \int_{f_{l,j}}^{f_{u,j}} W_{Aj}(f) \left\{ [\nabla_x A(x, f)]^2 + [A(x, f) - A_D(x, f)] \nabla_x^2 A(x, f) \right\} df$$

and the Hessian of the group delay error, \mathcal{E}_T , is similar.

Appendix I.6 shows that for a particular set of constraints, $\{g_i(x^k) \mid i \in \mathcal{A}(x^k)\}$, the IIR design problem can be approximated by

$$\mathcal{W}_k d^k - \mathcal{B}_k \lambda^k = -\nabla_x \mathcal{E}(x^k) \quad (8.8)$$

$$-\mathcal{B}_k^T d^k = g(x^k)$$

where \mathcal{W}_k is a positive-definite approximation to the true Hessian matrix derived using the *Broyden-Fletcher-Goldfarb-Shanno* formula (see Appendix I.7.1) and \mathcal{B}_k is the matrix whose columns are the gradients of the active constraints. This is a matrix equation that can be solved for the Lagrange multipliers λ^k and the direction vector d^k :

$$\begin{aligned}\lambda^k &= -(\mathcal{B}_k^T \mathcal{W}_k^{-1} \mathcal{B}_k)^{-1} [g(x^k) - \mathcal{B}_k^T \mathcal{W}_k^{-1} \nabla_x \mathcal{E}(x^k)] \\ d^k &= -\mathcal{W}_k^{-1} [\nabla_x \mathcal{E}(x^k) - \mathcal{B}_k \lambda^k]\end{aligned}$$

At each iteration of the sequential programming method the coefficient vector is updated by

$$x^{k+1} = x^k + \tau^k d^k$$

where d^k is the step direction vector and $\tau^k \in [0, 1]$ is the step-size. τ^k is found by a line search for the minimum of the Lagrangian function

$$\mathcal{L}(\tau^k) = \mathcal{E}(x^k + \tau^k d^k) - \sum_{i \in \mathcal{A}(x^k)} \lambda_i^k g_i(x^k + \tau^k d^k)$$

subject to the constraints. The iteration finishes when the *Karush-Kuhn-Tucker* conditions are satisfied.

8.1.2 Choice of active constraints

Selesnick, Lang and Burrus [58] describe a simple algorithm for selecting the constraints on the magnitude response that apply at each iteration in the design of an FIR filter. The general discussion accompanying that description is applicable here. The following applies equally to the group delay error component, \mathcal{E}_T , of the total error, \mathcal{E} .

The amplitude $A(f)$ of the filter response minimising the L_2 error subject to the peak constraints will touch the upper and lower bound functions at the extremal frequencies of $A(f)$. At each iteration of the algorithm, the set of frequency points at which $A(f)$ touches the constraints is updated. The equality-constrained problem is then solved by the method of Lagrange multipliers. According to the *Karush-Kuhn-Tucker* conditions, the solution to the *equality*-constrained problem solves the corresponding *inequality* constrained problem if all the Lagrange multipliers are non-negative (where the signs of the multipliers are defined appropriately). If on some iteration a multiplier is negative, then the solution to the equality-constrained problem does not solve the corresponding inequality-constrained one. For this reason, constraints corresponding to negative multipliers are sequentially dropped from the set of constraints. Although not proved in theory, this technique appears to converge in practice.

Let the constraint set S be the set of frequencies $S = \{f_1, \dots, f_r\}$ where $f \in [0, \pi]$. Let S be partitioned into two sets S_L and S_U , where S_L is the set of frequencies where the lower bounds apply

$$A(x, f) = L(f)$$

and S_U is the set of frequencies where the upper bounds apply

$$A(x, f) = U(f)$$

Suppose $S_L = \{f_1, \dots, f_q\}$ and $S_U = \{f_{q+1}, \dots, f_r\}$. To minimise $\mathcal{E}_A(x, f)$ subject to these constraints, form the Lagrangian

$$\mathcal{L}(x, \lambda) = \mathcal{E}_A(x, f) - \sum_{i=1}^q \lambda_i [A(x, f) - L(f)] - \sum_{i=q+1}^r \lambda_i [U(f) - A(x, f)]$$

At the minimum of $\mathcal{E}_A(x, f)$ the gradient $\nabla_x \mathcal{L}(x, \lambda) = 0$ and

$$\begin{aligned}\nabla_x \mathcal{E}_A(x, f) - \sum_{i=1}^q \lambda_i \nabla_x A(x, f) + \sum_{i=q+1}^r \lambda_i \nabla_x A(x, f) &= 0 \\ A(x, f_i) &= L(f_i) \quad \text{for } 1 \leq i \leq q \\ A(x, f_i) &= U(f_i) \quad \text{for } q+1 \leq i \leq r\end{aligned}$$

According to the *Karush-Kuhn-Tucker* conditions, when the Lagrange multipliers $\lambda_1, \dots, \lambda_r$ are all non-negative, then the solution to these equations minimises $\epsilon(x, f)$ subject to the inequality constraints

$$A(x, f_i) \geq L(f_i) \quad \text{for } 1 \leq i \leq q$$

Algorithm 8.1 Exchange algorithm for multiband FIR filters. (*Selesnick, Lang and Burrus*. See [59, p.498]).

1. *Initialisation*: Initialise the constraint sets R and S to the empty set.
 2. *Minimisation with Equality Constraints*: Calculate the Lagrange multipliers associated with the filter that minimizes $\mathcal{E}_A(\omega)$ subject to the equality constraints $A(\omega_i) = L(\omega_i)$ for $\omega \in S_L$, and $A(\omega_i) = U(\omega_i)$ for $\omega \in S_U$.
 3. *Karush-Kuhn-Tucker Conditions*: If there is a constraint set frequency ω_i , for which the Lagrange multiplier λ_i is negative, then remove from the active constraint set, S , the frequency corresponding to the most negative multiplier, and go back to step 2. Otherwise go on to step 4.
 4. *Check for Violation over R*: Calculate the new filter response, $A(\omega_i)$ for frequencies in the alternate constraint set, R . If $A(\omega_i) < L(\omega_i)$ or $A(\omega_i) > H(\omega_i)$ for some $\omega_i \in R$, then remove the frequency corresponding to the greatest violation from R , append that frequency to S , and go back to step 2.
 5. *Multiple Exchange of Constraint Set*: Overwrite the previous constraint set, R , with the current constraint set, S . Set the current constraint set S equal to $S_L \cup S_U$, where S_L is the set of frequency points ω , in $[0, \pi]$ satisfying both $A'(\omega_i) = 0$ and $A(\omega_i) \leq L(\omega_i)$ (ie: troughs failing the constraint) and where S_U , is the set of frequency points ω , in $[0, \pi]$ satisfying both $A'(\omega_i) = 0$ and $A(\omega_i) \geq U(\omega_i)$ (ie: peaks failing the constraint).
 6. *Check for Convergence*: If $A(\omega) \geq L(\omega) - \epsilon$ for all frequency points in S_L and if $A(\omega) \leq U(\omega) + \epsilon$ for all frequency points in S_U , then convergence has been achieved. Otherwise, go back to step 2.
-

$$A(x, f_i) \leq U(f_i) \quad \text{for } q+1 \leq i \leq r$$

Selesnick et al. [59, p.498] modify the algorithm of *Selesnick et al.* [58] so that it can be used in the design of multiband FIR filters, as shown in Algorithm 8.1. In the following, this algorithm is referred to as the Peak-Constrained-Least-Square (PCLS) error algorithm. The modification referred to is the addition of a second set of constraints. It avoids the cycling of constraint sets that otherwise occurs with multi-band filter designs.

Selesnick et al. [58, Section IV.A] justify the removal of the most negative Lagrange multiplier as follows:

The constraints are on the values of $A(\omega_i)$ for the frequency points ω_i in a constraint set. On each iteration, the constraint set is updated so that at convergence, the only frequency points at which equality constraints are imposed are those where $A(\omega)$ touches the constraint. The equality constrained problem is solved with Lagrange multipliers. The algorithm below associates an inequality-constrained problem with each equality constrained one. According to the Kuhn-Tucker conditions, the solution to the *equality* constrained problem solves the corresponding *inequality* constrained problem if all the Lagrange multipliers are non-negative (where the signs of the multipliers are defined appropriately). If on some iteration a multiplier is negative, then the solution to the equality constrained problem does not solve the corresponding inequality constrained one. For this reason, before the constraint set is updated in the algorithm described below, constraints corresponding to negative multipliers (when they appear) are sequentially dropped from the constraint set. In this way, an inequality constrained problem is solved on each iteration, albeit over a smaller constraint set. It turns out that in the special case of a lowpass filter design considered here, this simple iterative technique converges in practice.

Selesnick and Burrus have, in the past, published implementations of PCLS filter design in the files *cl2lp.m* and *cl2bp.m* that do not appear to be currently available [145] but are included in the source files for this project.

8.1.3 Linearisation of peak constraints

At each iteration the magnitude response and group-delay are linearised about x^k . I follow the description of the linearised constraints given by *Sullivan* [63, p.2855]. The linearised magnitude response is:

$$\hat{A}(x) = A(x^k) + \nabla_x A(x^k)^T (x - x^k)$$

The frequency response magnitude inequality constraints are, in the pass band

$$\begin{aligned} A_D - \hat{A}(x) &\geq 0 \\ \hat{A}(x) - [A_D - \Delta_{AP}] &\geq 0 \end{aligned}$$

and in the stop band

$$\Delta_{A_S} - \hat{A}(x) \geq 0$$

where Δ_{A_p} is the pass band ripple for the desired gain A_D and Δ_{A_S} is the stop band ripple. After linearising about x^k these constraints become

$$\begin{aligned} A_D - A(x^k) - \nabla_x A(x^k)^T (x - x^k) &\geq 0 \\ A(x^k) + \nabla_x A(x^k)^T (x - x^k) - [A_D - \Delta_{A_P}] &\geq 0 \\ \Delta_{A_S} - A(x^k) - \nabla_x A(x^k)^T (x - x^k) &\geq 0 \end{aligned}$$

Similarly, the linearised group-delay is

$$\hat{T}(x) = T(x^k) + \nabla_x T(x^k)^T (x - x^k)$$

and the group-delay inequality constraints in the pass band are

$$\begin{aligned} [T_D + \Delta_D] - \hat{T}(x) &\geq 0 \\ \hat{T}(x) - [T_D - \Delta_T] &\geq 0 \end{aligned}$$

where $\Delta_T = T_{\max} - T_D = T_D - T_{\min}$ is the tolerance for the group-delay error compared with the desired group-delay T_D . As before, the two corresponding linearised constraints on the group-delay in the pass band are

$$\begin{aligned} [T_D + \Delta_T] - T(x^k) - \nabla_x T(x^k)^T (x - x^k) &\geq 0 \\ T(x^k) + \nabla_x T(x^k)^T (x - x^k) - [T_D - \Delta_T] &\geq 0 \end{aligned}$$

The frequency response inequality constraints are calculated at a grid of frequency points. For a low-pass filter there are two amplitude constraints and two group-delay constraints in the pass band and one amplitude constraint in the stop band.

8.1.4 Ensuring the stability of the IIR filter

An IIR filter is stable if the poles of the filter transfer function lie within the unit circle: $|z| < R < 1$. *Deczky* [3] and *Richards* [85] define the transfer function in the form of gain, pole locations and zero locations. In this case filter stability is ensured by a simple constraint on the pole radius.

The partial differentials of the amplitude response with respect to the filter coefficients are simpler when expressed in terms of the numerator and denominator polynomials of the transfer function. This has lead many authors to suggest filter stability criteria expressed in terms of the coefficients of the denominator polynomial. *Tarczynski et al.* [9] ensure stability by adding a *barrier* function to the squared error based on the impulse response of the digital filter that corresponds to the denominator polynomial of the filter transfer function being optimised. *Lang* [87] describes a method for finding successive coefficient vectors based on Rouché's theorem. *Dumitrescu and Niemistö* [17] compare Lang's method with one that ensures that the updated denominator polynomial remains a Schur polynomial in the vicinity of the current coefficient vector. *Lu and Hinamoto* [160] express the denominator polynomial as a product of second-order sections and derive a linear inequality stability constraint on the denominator coefficients. *Lu* [168] describes a stability test based on Cauchy's Argument Principle.

In my opinion, expressing the filter transfer function in the gain-pole-zero form is preferable to the usual polynomial fraction form because the former provides the simplest possible stability criterion.

8.1.5 Selecting an initial filter design

The constraints on the filter design are the desired response and stability.

Windowed FIR initial filters

An FIR filter approximating the desired response can be designed with the Octave *remez* function. Alternatively, the FIR filter can be designed with the “windowing” method, summarised here. The frequency response of a digital filter

$$H(z) = \sum_{k=-\infty}^{\infty} h_k z^{-k}$$

with a lowpass response cutoff at ω_p is

$$\begin{aligned} H(\omega) &= \sum_{k=-\infty}^{\infty} h_k e^{-ik\omega} \\ &= \begin{cases} 1, & |\omega| < \omega_p \\ 0, & \omega_p < |\omega| < \pi \end{cases} \end{aligned}$$

The coefficients of the impulse response are

$$\begin{aligned} h_k &= \frac{1}{2\pi} \int_{-\omega_p}^{\omega_p} e^{ik\omega} d\omega \\ &= \frac{1}{\pi k} \sin k\omega_p \\ &= \frac{\omega_p}{\pi} \operatorname{sinc} k\omega_p \end{aligned}$$

To create an FIR response we truncate the response to length $L = 2N + 1$ with a window function. The window function is selected for main-lobe width and side-lobe suppression. A typical window function is

$$W_k = \begin{cases} [\alpha + (1 - \alpha) \cos \frac{2\pi k}{N}], & |k| \leq N \\ 0, & |k| > N \end{cases}$$

For the Hamming window, $\alpha = 0.54$. The Octave code to implement a windowed FIR filter is:

```
b=2*f c*sinc((-((L-1)/2):((L-1)/2))*2*f c).*hamming(L)
```

where L is the FIR filter length and $fc < 0.5$ is the low-pass cut-off frequency for sampling frequency $f_s = 1$.

Tarczynski's method of unconstrained optimisation of an IIR initial filter

An arbitrary filter can be refined by unconstrained optimisation with a “barrier” function (see Appendix I.8.2). Tarczynski *et al.* [9], propose minimising the error with the following, so-called, WISE barrier function:

$$(1 - \lambda) \mathcal{E}_H + \lambda \sum_{t=T+1}^{T+M} f^2(t) \quad (8.9)$$

where \mathcal{E}_H is the filter response error defined in Equation 1, λ , T and M are suitable constants and $f(t)$ is the impulse response of the filter $F(z) = \frac{1}{D(z)}$. Tarczynski *et al.* provide heuristics for selecting λ , T and M . Typically, $\lambda \in [10^{-10}, 10^{-3}]$, $T \in [100, 500]$ and $M = RK$. The barrier function (the second part of Equation 8.9) is intended to be small when the filter is stable and increase rapidly otherwise. Roberts and Mullis [129, Section 8.3] show that the state space description of the direct-form implementation of $F(z)$ is:

$$\begin{bmatrix} x(t+1) \\ y(t) \end{bmatrix} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} x(t) \\ u(t) \end{bmatrix}$$

where:

$$\begin{aligned} A &= \begin{bmatrix} 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \\ -d_{N_d} & -d_{N_d-1} & \cdots & -d_1 \end{bmatrix} \\ B &= [0 \ 0 \ \cdots \ 0 \ 1]^T \\ C &= [-d_{N_d} \ \cdots \ -d_1] \\ D &= 1 \end{aligned}$$

Alternatively, for the filter transfer function, $H(z)$, given by Equation 8.1, Tarczynski *et al.* [9, Appendix 1] show that the filter $\frac{z^{-N_d}}{D(\rho z)}$ can be implemented as a cascade of first order sections, $\frac{z^{-1}}{1-p_i(\rho z)^{-1}}$. $0 < \rho < 1$ is chosen to limit the pole magnitudes. Let

the output of the i th section, y_i , be the input to the $i + 1$ th section, u_{i+1} , and assume the poles are ordered so that $|p_1| \geq |p_2| \geq \dots \geq |p_{N_d}|$, then the state space model for each section is:

$$\begin{aligned}x_i(t+1) &= p_i \rho^{-1} x_i(t) + u_i(t) \\y_i(t) &= x_i(t)\end{aligned}$$

The overall state space model is (for $R = 1$):

$$\begin{aligned}A &= \begin{bmatrix} p_1 \rho^{-1} & 0 & 0 & \cdots & 0 \\ 1 & p_1 \rho^{-1} & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 & p_{N_d} \rho^{-1} \end{bmatrix} \\B &= [1 \ 0 \ \dots \ 0 \ 0]^T \\C &= [0 \ 0 \ \dots \ 0 \ 1] \\D &= 0\end{aligned}$$

In both cases, the corresponding impulse response is:

$$f(t) = \begin{cases} 0 & t < 0 \\ D & t = 0 \\ CA^{t-1}B & t > 0 \end{cases}$$

Golub and van Loan [38, Algorithm 11.2.2] show an algorithm, reproduced as Algorithm 8.2, for efficiently computing the powers of a matrix by cumulative products of the binary powers of the matrix. This algorithm requires at most $2 \times \text{floor}[\log_2(s)]$ matrix multiplies. If s is a power of 2, then only $\log_2(s)$ matrix multiplies are needed.

Algorithm 8.2 Compute the powers of a matrix (see *Golub and van Loan*, Algorithm 11.2.2)

The following algorithm computes $F = A^s$ for matrix $A \in \mathbb{R}^{n \times n}$ and a positive integer s with binary expansion $s = \sum_{k=0}^K \beta_k 2^k$.

```
Z = A, q = 0
while β_q = 0 do
    Z = Z^2
    q = q + 1
end while
F = Z
for k = q + 1, ..., t do
    Z = Z^2
    if β_k ≠ 0 then
        F = FZ
    end if
end for
```

The Octave script *tarczynski_ex2_standalone_test.m*, designs a filter for the specifications of *Tarczynski et al.* Example 2 [9] with $nN = 24$, $nD = 2$ and $R = 2$ by unconstrained minimisation of Equation 8.9 with *fminunc*. The resulting response is shown in Figure 8.1 and the pole-zero plot of the filter is shown in Figure 8.2.

The Octave function *xInitHd* uses the WISE barrier function to design an initial filter in polynomial form and then calls the Octave *qroots* function to convert that polynomial into *gain-pole-zero* form. As noted in the Introduction, finding the roots of a polynomial is a difficult problem in numerical analysis and the output of the *qroots* function depends on the CPU architecture, operating system, library versions, compiler version and Octave version.

Surma-aho and Saramäki method of designing an IIR initial filter

Appendix K.4.3 describes the method of *Surma-aho* and *Saramäki* [71] for designing an initial low-pass filter implemented as either a single filter or as the parallel combination of two all-pass filters. Unfortunately, this method requires root-finding of intermediate polynomials. I find the method of *Tarczynski et al.* to be more useful.

with

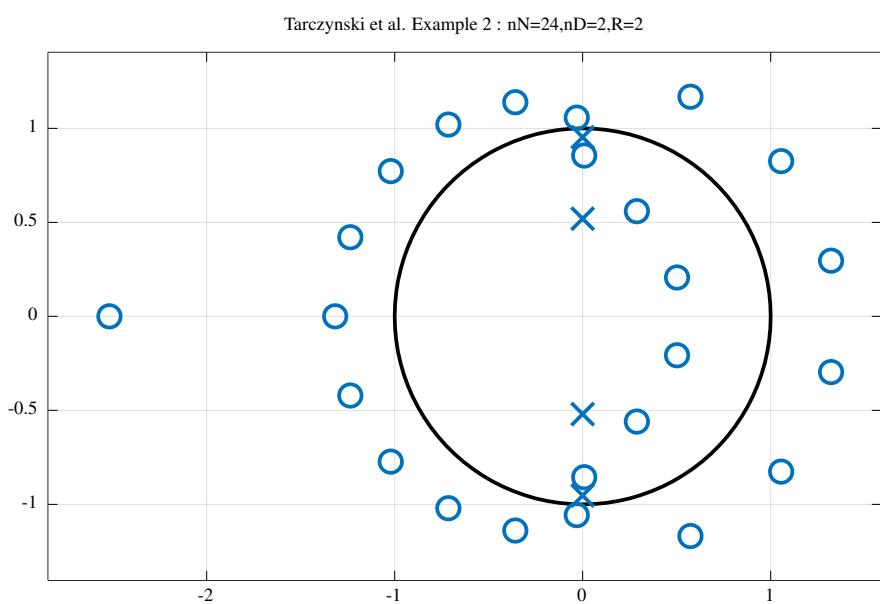

Figure 8.2: Tarczynski et al. Example 2 : Pole-zero plot for $nN=24$, $nD=2$ and $R=2$

8.2 Examples of IIR filter design with SQP and constrained pole and zero locations

8.2.1 Introductory comments on the IIR filter design examples

This section considers examples of IIR filter design. The design procedure is:

- find a valid initial design
- iteratively reduce the mean-square-error (MMSE) with the procedure described in Section 8.1.1.
- iteratively apply constraints with the peak-constrained-least-square-error (PCLS) algorithm described in Section 8.1.2.

For the filter design examples in this section, the filter amplitude, phase and group delay responses and their gradients are calculated by the Octave functions *iirA*, *iirP* and *iirT*, respectively.

Finding an initial IIR filter design

The initial IIR filter design must be stable and bear a passing resemblance to the desired response. The multi-dimensional IIR filter design surface has many local minima and the minimum reached depends on the initial point. After deciding the decimation ratio, R , a stable initial design can be found with:

- an FIR filter and an estimate of the number of poles required
- an arbitrary IIR filter optimised with the Octave function *xInitHd*

The Octave function *xInitHd* begins with an initial filter and designs a rational polynomial transfer function approximation to the desired response by repeated calls to the Octave *fminunc* function. Filter stability is assured by a barrier function based on the impulse response of a filter constructed from the poles of the approximate response. See Section 8.1.5 and *Tarczynski et al.* [9]. The coefficient constraints are defined in the Octave function *xConstraints*. In fact I only constrain the pole radiiuses and do not constrain the scale factor, K , or the complex conjugate pole angles. It is possible that the initial filter produced by *xInitHd* has a negative scale factor and the filter amplitude response is real but negative. See, for example, the initial filter of the $R=2$ decimator filter below. Presumably, the filter was found at a minimum so reversing the sign of the scale factor reverses the sign of the initial amplitude gradients. In practice, a first pass of MMSE optimisation will (hopefully!) reverse the sign of K to match the sign of the desired response while, at the same time, finding a new minimum. The constraints applied to the amplitude response by the implementation of PCLS optimisation in *iir_slb* assume that the amplitude function is positive so an attempt at PCLS optimisation of a filter with a negative scale factor will most likely fail.

Appendix I.10 works through the derivation of the *Goldfarb-Idnani* algorithm [25] for finding an initial solution that meets constraints. As an example, the Octave script *goldfarb_idnani_fir_minimum_phase_test.m* begins with a non-minimum phase FIR bandpass filter and finds a minimum phase FIR filter, that is, an FIR bandpass filter with the constraint that the zero locations lie on or within the unit circle. When the number of constraints on the frequency response is more than ten or so the script fails due to numerical problems with the Hessian matrix. The script does find a minimum-phase FIR filter albeit with a very poor response. In this case I found that a “by-eye” or “cut-and-fit” iterative approach to finding an initial filter is more useful. For example see the Octave script *iir_sqp_slb_fir_bandpass_test.m*.

MMSE optimisation

MMSE optimisation is performed by calling Octave function *iir_sqp_mmse*. The response error is minimised while the real and complex pole radiiuses are constrained to $|r| < rho < 1$. The other parts of the coefficient vector (scale factor, zero radiiuses and pole and zero angles) are not constrained. The *vS* argument to *iir_sqp_mmse* specifies the indexes into the frequency vectors ω_a etc. of linear constraints at the corresponding index into A_{du} or A_{dl} etc. Function *iir_sqp_mmse()* calls *sqp_bfgs* to minimise the objective function *iir_sqp_mmse_fx()* with linear constraints calculated by *iir_sqp_mmse_gx()*. These functions calculate the squared-error in the response amplitude and delay and linear constraints by calls to *iirE()*. That function calculates the error with trapezoidal integration. If the frequency bands are not contiguous then zeros in the weight vector can make frequency transition bands. A useful future improvement is to add a constraint on the slope of the amplitude response in the transition band. For a lowpass filter: $\frac{\partial A}{\partial \omega} < 0$.

I found by trial-and-error when running *iir_sqp_mmse* that the SQP Hessian matrix can be initialised with the diagonal elements of the amplitude squared error Hessian. Similarly, the current SQP search point can be updated with the *Armijo-Kim* line-search algorithm and the *Broyden-Fletcher-Goldfarb-Shanno*(BFGS) Hessian matrix update algorithm (see Appendix I.9.2 and Appendix I.7.1 respectively). The error surface is not quadratic and has many, many local minima. The SQP loop is more stable if, at each iteration, the error surface is approximated by a quadratic surface with the BFGS estimate of the Hessian matrix. Typically, the MMSE optimisation process is iterative; the design process starts with a loose amplitude only specification and the constraints on amplitude, phase and delay are gradually tightened.

There are several reasons why an optimisation attempt might fail:

- the weighting factors for the combined squared error of, for example, amplitude and group delay, are not appropriate. Experiment with the weights.
- the number of iterations may exceed the limit. Increase the iteration limit, *maxiter*,
- the tolerance used may be too low. Increase the tolerance, *tol*.
- the line-search direction does not satisfy the constraints:

```
warning: searching for d within constraints but norm(d)<tol^2!
```

Reduce the maximum coefficient update size, *dmax*.

- the line-search algorithm may not find a minimum or the line-search algorithm may find that the objective function is not approximately quadratic in the search region:

```
Found tau = 0.000000 using goldensection search of Lagrangian
warning: norm(delta)<eps
```

Octave includes an SQP solver function, *sqp*. I have not used this function because it calls separate functions to calculate the error and the constraints. In *iir_sqp_mmse* and in the PCLS solver, *iir_slb*, the constraints are calculated at the same time as the error.

PCLS optimisation

The MMSE optimisation constrains the integrated error over a frequency interval. PCLS optimisation constrains the peaks of the amplitude, phase and group-delay responses. For example, the MMSE design of a low-pass filter may have amplitude peaks above 0dB. The PCLS algorithm of *Selesnick, Lang and Burrus* [59, Fig.4,p.499] (reproduced above as Algorithm 8.1), is implemented in the Octave function *iir_slb*. The function handle of the MMSE solver (in this case *iir_sqp_mmse*) is an argument to *iir_slb*. The peak-exchange algorithm of *Selesnick et al.* is much simpler than that of Adams and Sullivan [66, Section IV].

Figure 8.3 shows the failed constraints for the amplitude response of a low pass filter with an amplitude constraint mask. The figure was generated by the Octave script *iir_slb_update_constraints_test.m*. When switching from MMSE to PCLS optimisation, the introduction of constraints on the response peaks alters the Lagrangian and the pass-band and stop-band weights must be modified by trial-and-error.

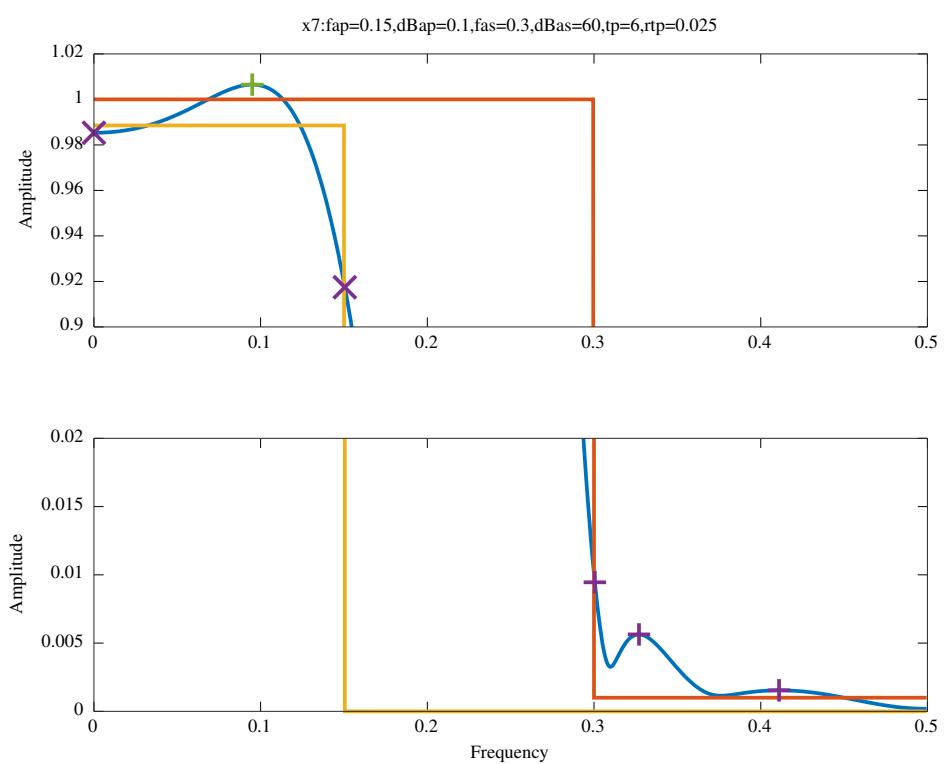

Figure 8.3: Example of failed constraints for a low pass filter

8.2.2 Tarczynski et al. Example 2

Figure 8.1 shows the response of a filter designed with the “WISE” method of *Tarczynski et al.* [9]. The coefficients of the numerator and denominator polynomials of the filter are:

```
N0 = [ 0.0055320618, 0.0168964837, 0.0074753205, -0.0015215157, ...
-0.0019749902, 0.0069418960, 0.0033977155, -0.0102842193, ...
-0.0055116039, 0.0171241990, 0.0104427562, -0.0353411253, ...
-0.0284877776, 0.1348446063, 0.4155080556, 0.6323659783, ...
0.6374906164, 0.4464472313, 0.1789025959, -0.0679315564, ...
0.2506270828, -0.3305093421, 0.2960012842, -0.1721597661, ...
0.0604551723 ]';

D0 = [ 1.0000000000, 1.1782055247, 0.2453761906 ]';
```

In the above listing, the first line shows the gain, and subsequent lines show, respectively, 2 real zeros, 2 real poles, the zero radiiuses for 11 conjugate pairs of zeros and the zero angles for 11 conjugate pairs of zeros. In practice, since $R = 2$, the real poles are split into pairs of conjugate poles lying on the imaginary axis. After some experimentation I modified the filter to:

```
Ux0=3,Vx0=2,Mx0=20,Qx0=0,Rx0=2
x0 = [ 0.0400000000, ...
-1.1000000000, 0.3617300000, 0.3617300000, ...
-0.8842894000, -0.1495357000, ...
0.6034298000, 0.8306859000, 1.0533570000, 1.1899991000, ...
1.2418447000, 1.2794257000, 1.3011204000, 1.3091281000, ...
1.3386509000, 1.3538295000, ...
0.9197805000, 1.5328472000, 1.6013209000, 1.8790233000, ...
2.1870677000, 2.5029369000, 1.1173639000, 2.8187821000, ...
0.6631062000, 0.2204128000 ]';
```

In this case there are three real zeros. The Octave script *iir_sqp_mmse_tarczynski_ex2_test.m* calls the *iir_sqp_mmse()* function to MMSE optimise this filter. The optimised filter is:

```
Ux1=3,Vx1=2,Mx1=20,Qx1=0,Rx1=2
x1 = [ 0.0007284179, ...
-1.4714295893, 0.3837672013, 0.3837672013, ...
-0.2813064757, -0.0198520460, ...
0.5473333261, 0.6749732829, 1.4011268507, 1.4262036800, ...
1.4508467031, 1.4593352951, 1.4665517411, 1.5954735335, ...
1.6080735861, 1.6179179045, ...
0.8977245732, 1.4766584241, 1.8431553308, 2.2454091799, ...
2.5512336262, 1.8596988558, 2.8478478354, 1.0849400446, ...
0.6694755118, 0.2132656643 ]';
```

The corresponding transfer function numerator and denominator polynomials are, respectively:

```
N1 = [ 0.0007284179, 0.0009506175, -0.0000630177, -0.0013084404, ...
-0.0000329191, 0.0035439010, 0.0005607686, -0.0106002115, ...
-0.0065587949, 0.0202747709, 0.0158572364, -0.0470169053, ...
-0.0438042385, 0.1674764860, 0.4572672455, 0.5013163835, ...
0.2325921682, -0.0302449423, -0.0110956785, 0.1772964945, ...
-0.2390867472, 0.1800912029, -0.0822705450, 0.0142923214 ]';
```

and

```
D1 = [ 1.0000000000, 0.0000000000, 0.3011585217, 0.0000000000, ...
0.00555845091 ]';
```

Figure 8.4 shows the response of the optimised filter, Figure 8.5 shows the pass-band response and Figure 8.6 shows the corresponding pole-zero plot.

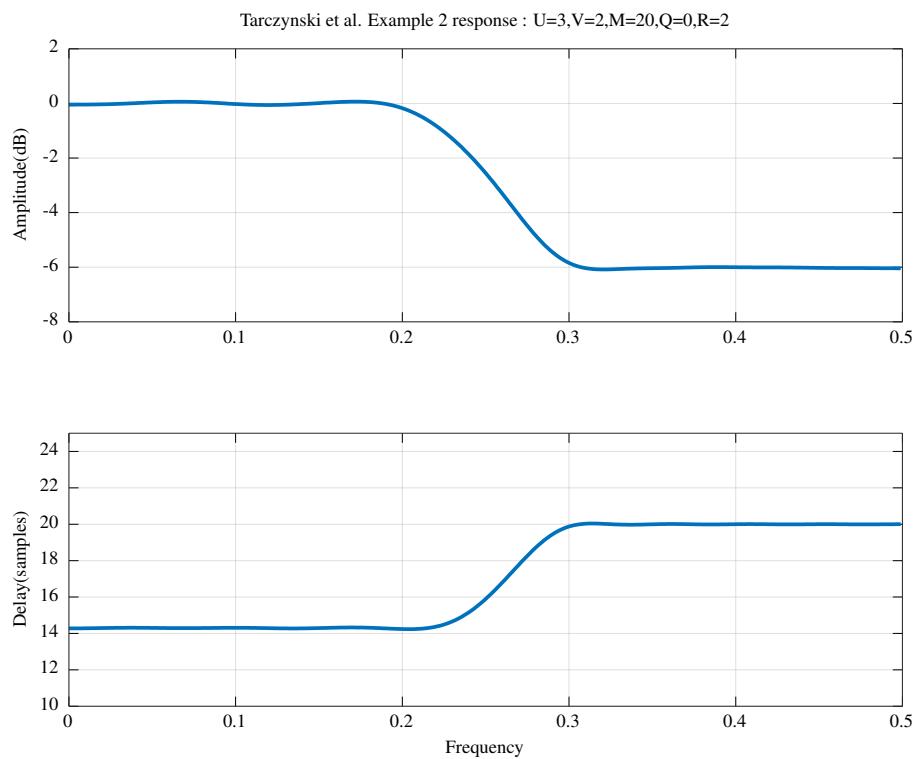

Figure 8.4: Tarczynski et al. Example 2 : Response after MMSE optimisation

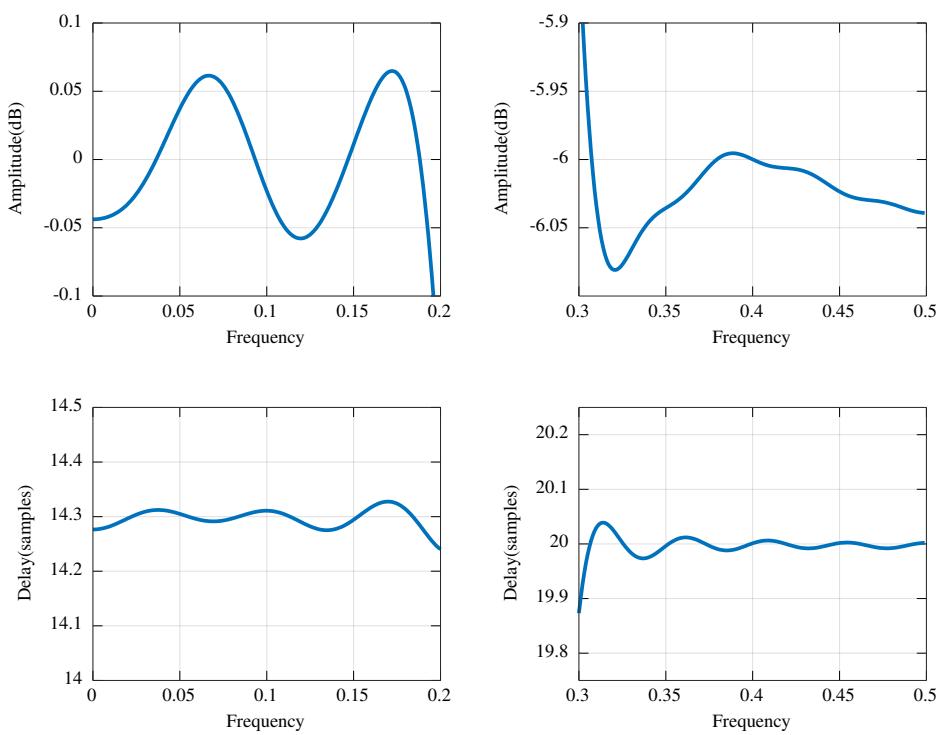

Figure 8.5: Tarczynski et al. Example 2 : Pass-band response after MMSE optimisation

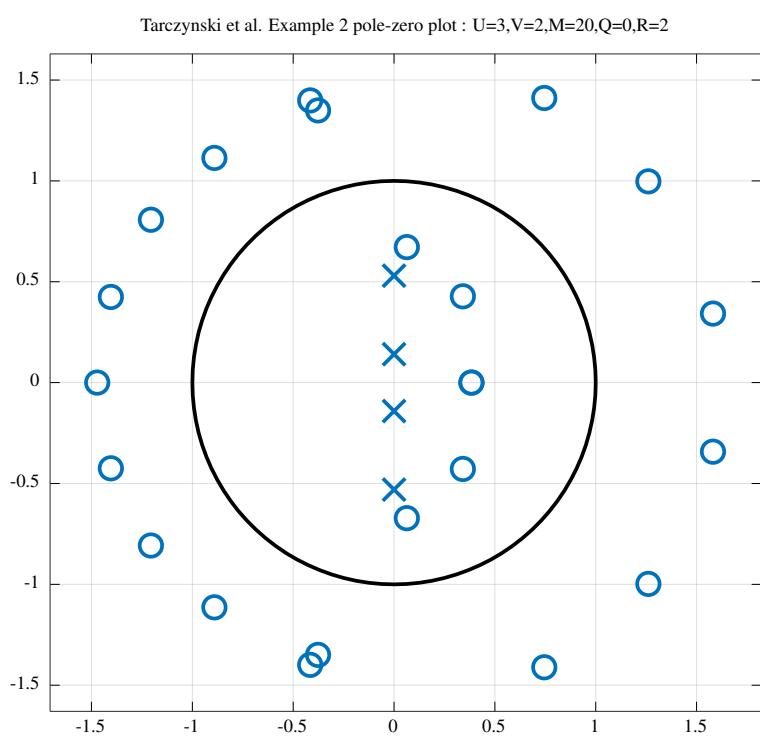

Figure 8.6: Tarczynski et al. Example 2 : Pole-zero plot after MMSE optimisation

8.2.3 Deczky's Example 3

Sullivan and Adams [63, p. 2859] refer to the following example IIR filter design specification as “*Filter 2-iv*”. It is a modified version of Deczky’s Example 3, [3].

$$\begin{aligned} U &= 0 \\ V &= 0 \\ M &= 10 \\ Q &= 6 \\ R &= 1 \\ A(f) &= \begin{cases} 1 & 0 < f < 0.15 \\ 0 & 0.3 < f < 0.5 \end{cases} \\ T(f) &= 10.00 \quad 0 < f < 0.25 \end{aligned}$$

The Octave script *deczky3_sqp_test.m* implements this example. The filter specification defined in that file is

```
n=1000 % Frequency points across the band
tol=0.0002 % Tolerance on relative coefficient update size
ctol=0.0002 % Tolerance on constraints
fap=0.15 % Pass band amplitude response edge
dBap=0.1 % Pass band amplitude peak-to-peak ripple
Wap=1 % Pass band weight
ftp=0.25 % Pass band group delay response edge
tp=10 % Nominal filter group delay
tpr=0.004 % Pass band group delay peak-to-peak ripple
Wtp_mmse1=0.25 % Pass band group delay weight (MMSE pass 1)
Wtp_mmse2=0.5 % Pass band group delay weight (MMSE pass 2)
Wtp_pcls=3 % Pass band group delay weight (PCLS pass)
fas=0.3 % Stop band amplitude response edge
dBas=30 % Stop band minimum attenuation
Was=1 % Stop band amplitude weight
U=0 % Number of real zeros
V=0 % Number of real poles
M=10 % Number of complex zeros
Q=6 % Number of complex poles
R=1 % Denominator polynomial decimation factor
```

Sullivan and Adams initialise the filter coefficients with a set of coefficients called “IPZS-1” [63, IPZS-1, p. 2860]

```
z=[exp(j*2*pi*0.41),exp(j*2*pi*0.305), ...
1.5*exp(j*2*pi*0.2),1.5*exp(j*2*pi*0.14),1.5*exp(j*2*pi*0.08)];
p=[0.7*exp(j*2*pi*0.16),0.6*exp(j*2*pi*0.12),0.5*exp(j*2*pi*0.05)];
K=0.0096312406;
x0=[K,abs(z),angle(z),abs(p),angle(p)]';
```

The above listing shows that the initial filter has 0 real zeros, 0 real poles, 5 conjugate pairs of zeros, and 3 conjugate pairs of poles. The initial response is shown in Figure 8.7. The corresponding pole-zero plot is shown in Figure 8.8.

MMSE optimisation of Deczky’s Example 3

With weights $W_{ap} = W_{as} = 1$ and $W_{tp} = 0.25$ the first MMSE optimisation pass gives the response shown in Figure 8.9. After some experimentation, the second iteration, with $W_{tp} = 0.5$, gives the response shown in Figure 8.10 with pass-band details shown in Figure 8.11 and the pole-zero plot shown in Figure 8.12.

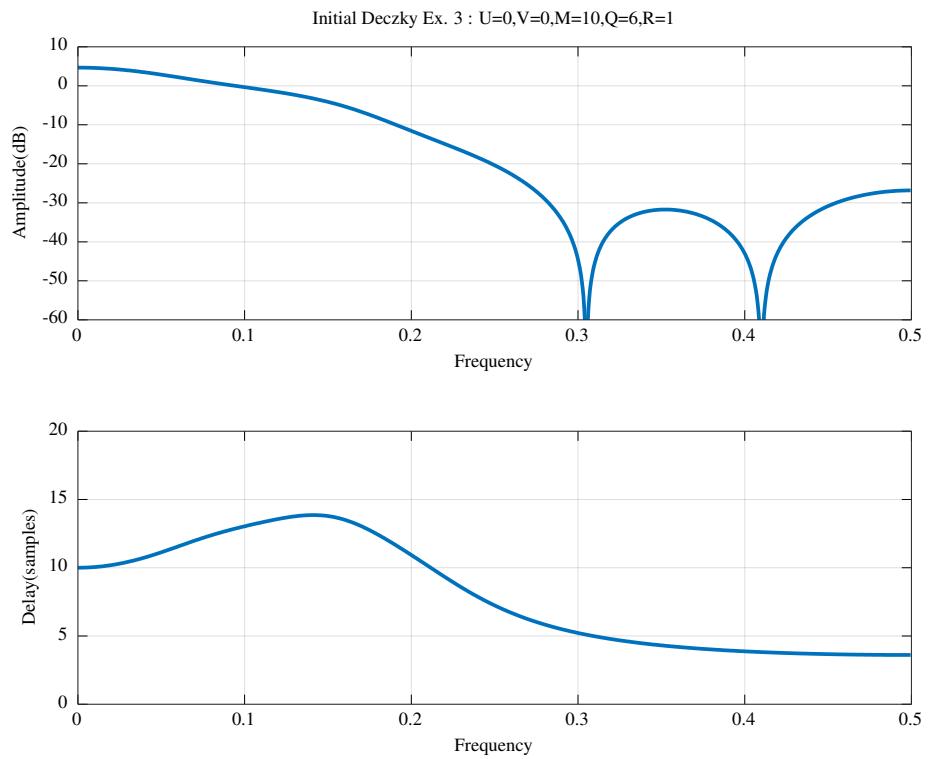

Figure 8.7: Deczky Example 3 : Response for initial coefficients

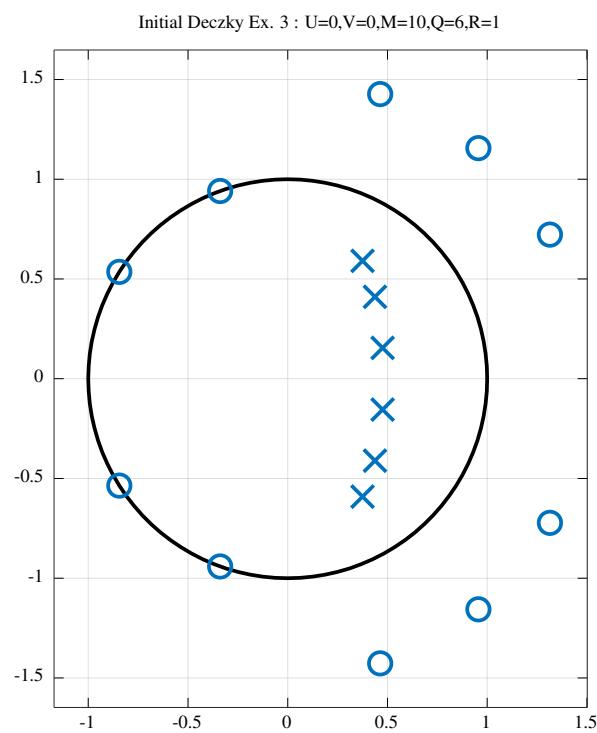

Figure 8.8: Deczky Example 3 : Pole-zero plot for initial coefficients

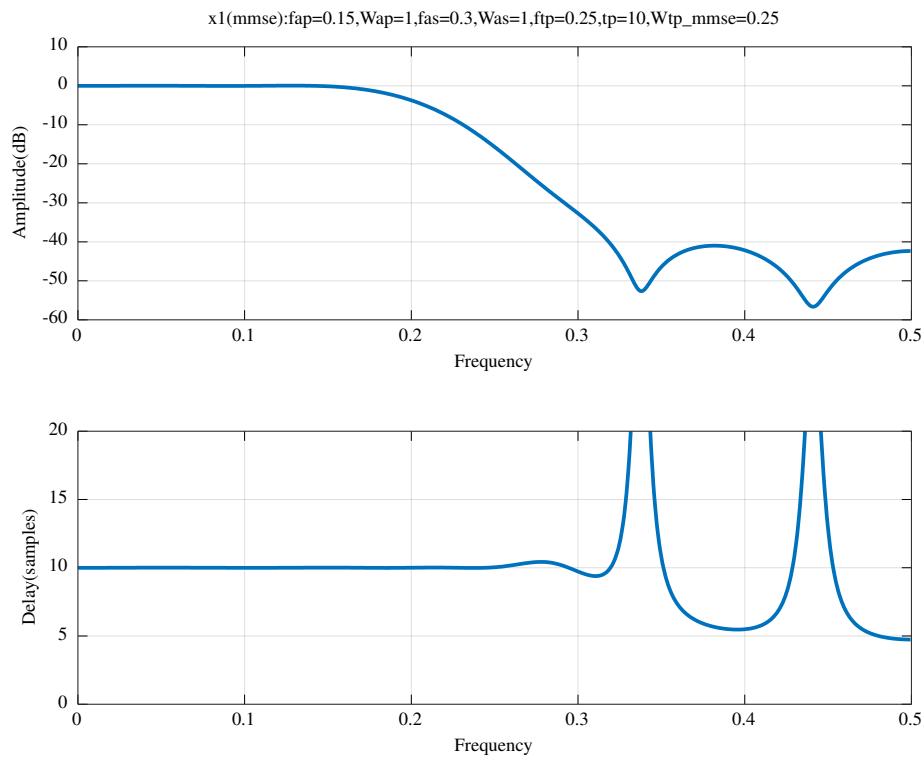

Figure 8.9: Deczky Example 3 MMSE pass 1 : Optimised response with Wap=1, Wtp=0.25, Was=1

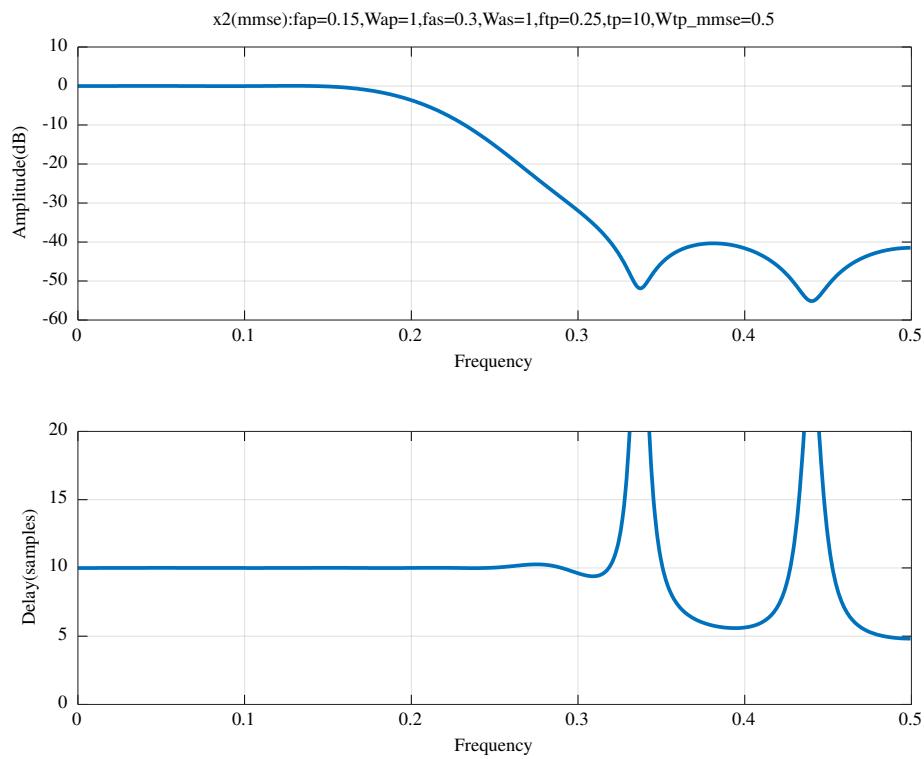

Figure 8.10: Deczky Example 3 MMSE pass 2: Optimised response with Wap=1, Wtp=0.5, Was=1

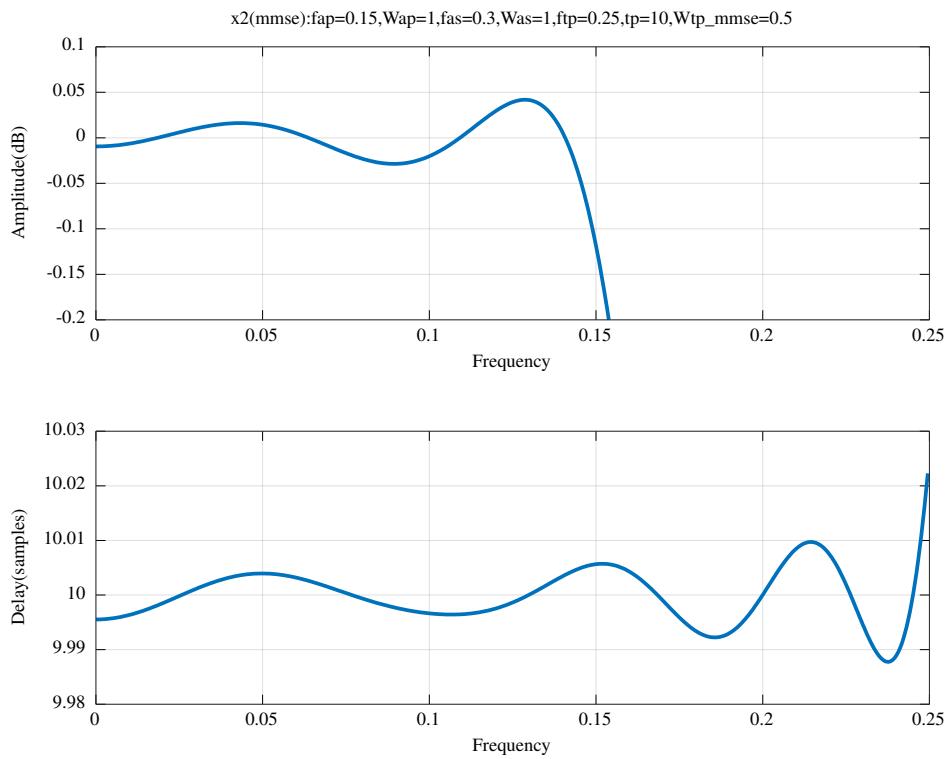

Figure 8.11: Deczky Example 3 MMSE pass 2: Optimised passband response with Wap=1, Wtp=0.5, Was=1

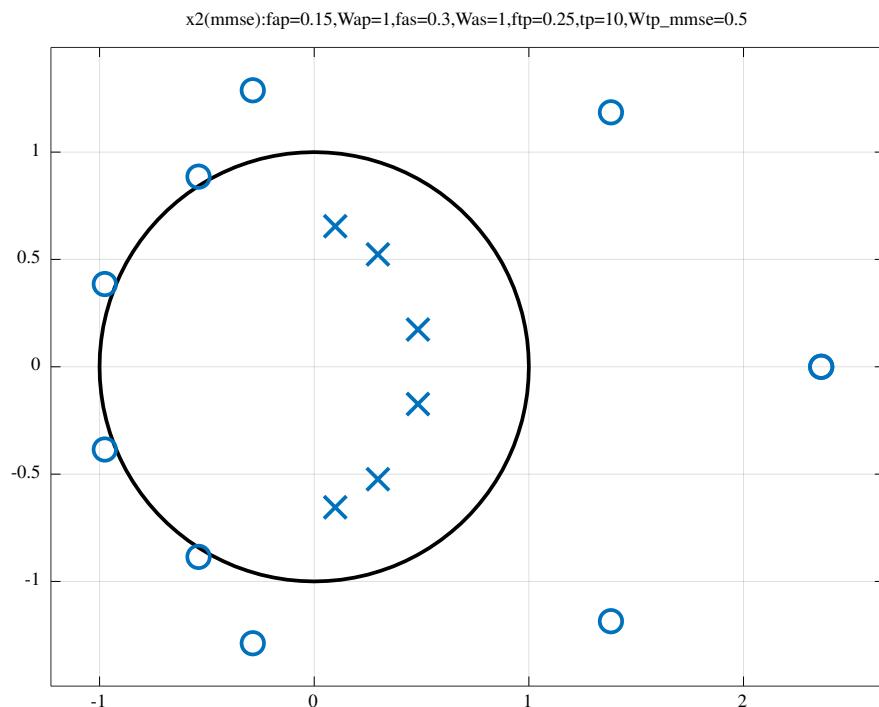

Figure 8.12: Deczky Example 3 MMSE pass 2: Pole-zero plot after optimisation with Wap=1, Wtp=0.5, Was=1

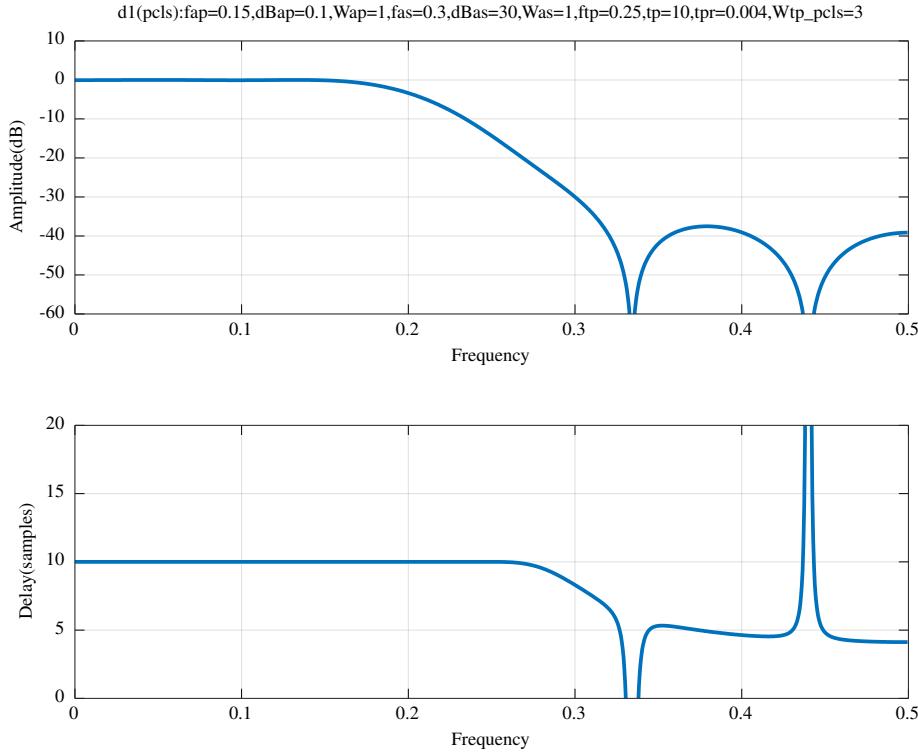

Figure 8.13: Deczky Example 3 PCLS : Optimised response with $dBap=0.1$, $tp=10$, $tpr=0.0035$, $dBas=30$

PCLS optimisation of Deczky's Example 3

The test script *deczky3_sqp_test.m* now switches to PCLS optimisation of the MMSE filter. After some experimentation, the final specification becomes $fap = 0.15$, $dBap = 0.1dB$, $Wap = 1$, $fas = 0.30$, $dBas = 30dB$, $Was = 1$, $ftp = 0.25$, $Wtp = 3$, $tp = 10$ samples group delay and $tpr = 0.0035$ samples of peak-to-peak group delay ripple. The resulting amplitude and delay responses are shown in Figure 8.13 with pass-band detail shown in Figure 8.14. The corresponding pole-zero plot is shown in Figure 8.15. The optimised filter vector is, in the gain, zeros and poles form of Equation 8.2:

```
Ud1=0,Vd1=0,Md1=10,Qd1=6,Rd1=1
d1 = [ 0.0031338874, ...
        0.9963385547, 1.0024785141, 1.3616224104, 1.7727139039, ...
        2.2760748087, ...
        2.0998152221, 2.7645321868, 1.7485665449, 0.7230504889, ...
        0.0089453392, ...
        0.5163645229, 0.5998436933, 0.6435399629, ...
        0.3543133769, 1.0872949784, 1.4295412380 ]';
```

and the corresponding transfer function numerator and denominator polynomials (found with Octave function *x2tf*) are, respectively:

```
N1 = [ 0.0031338874, -0.0120934910, 0.0105541716, -0.0026199457, ...

An alternative implementation of Deczky's Example 3

The test script *deczky3a_sqp_test.m* is an alternative implementation of Deczky's Example 3 with $fap = 0.15$, $dBap = 0.2dB$, $Wap = 1$, $fas = 0.30$, $dBas = 51dB$, $Was = 10$, $ftp = 0.25$, $Wtp = 0.001$, $tp = 9.35$ samples group delay and $tpr = 0.3$ samples of peak-to-peak group delay ripple. The resulting amplitude and delay responses are shown in Figure 8.16 with passband detail shown in Figure 8.17. The corresponding pole-zero plot is shown in Figure 8.18. The PCLS optimised filter vector is, in gain-zero-pole form:

```
Ud1=0,Vd1=0,Md1=10,Qd1=6,Rd1=1
d1 = [ 0.0007638996, ...
        1.0162153265, 1.0584900781, 1.0836456727, 2.0367457018, ...

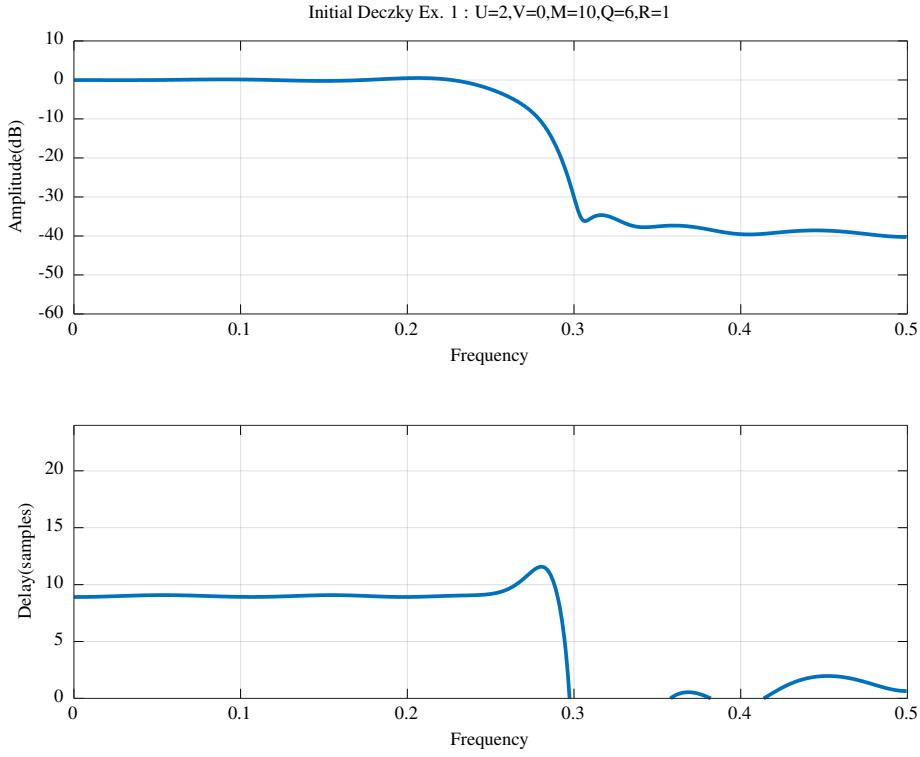

Figure 8.19: Deczky Example 1 : Response for initial coefficients

8.2.4 Deczky's Example 1

The following example IIR filter design specification is similar to *Deczky's Example 1* [3]. The pass-band is $[0.0, 0.25]$ with $1dB$ maximum amplitude ripple, the pass-band delay is 8 samples with 2 sample maximum peak-to-peak ripple and the stop band is $[0.3, 0.5]$ with at least $36dB$ attenuation. The PCLS optimisation in this example includes a constraint on the derivative of the amplitude response in the transition band: $\frac{\partial A(\omega)}{\partial \omega} < 0$. The Octave script *deczky1_sqp_test.m* implements this example. The filter specification defined in that file is:

```

n=400 % Frequency points across the band
tol=0.0002 % Tolerance on relative coefficient update size
ctol=2e-06 % Tolerance on constraints
fap=0.25 % Pass band amplitude response edge
dBap=1 % Pass band amplitude peak-to-peak ripple
Wap=1 % Pass band weight
Wat=0.01 % Transition band weight
ftp=0.25 % Pass band group delay response edge
tp=8 % Nominal filter group delay
tpr=2 % Pass band group delay peak-to-peak ripple
Wtp=0.01 % Pass band group delay weight
fas=0.3 % Stop band amplitude response edge
dBas=36 % Stop band minimum attenuation
Was=1 % Stop band amplitude weight
U=2 % Number of real zeros
V=0 % Number of real poles
M=10 % Number of complex zeros
Q=6 % Number of complex poles
R=1 % Denominator polynomial decimation factor

```

The initial filter design was found with the Octave script *tarczynski_deczky1_test.m*. The initial frequency response is shown in Figure 8.19.

MMSE optimisation of Deczky's Example 1

The frequency response after MMSE optimisation is shown in Figure 8.20 and the pole-zero plot is shown in Figure 8.21.

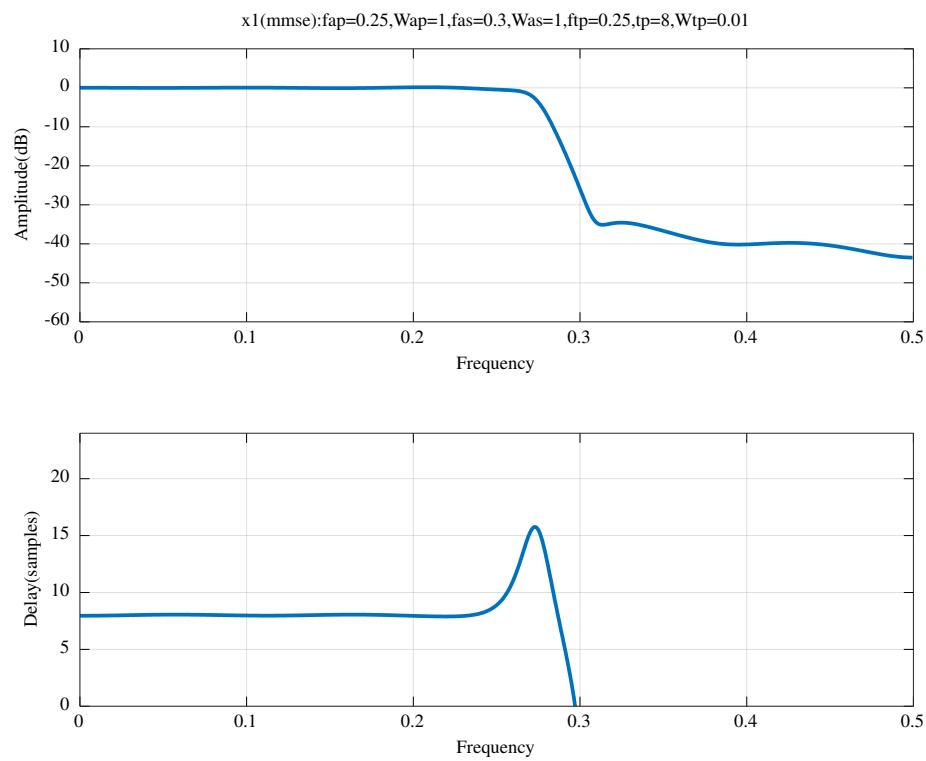

Figure 8.20: Deczky Example 1 : MMSE optimised response with Wap=1, Wtp=0.01, Was=1

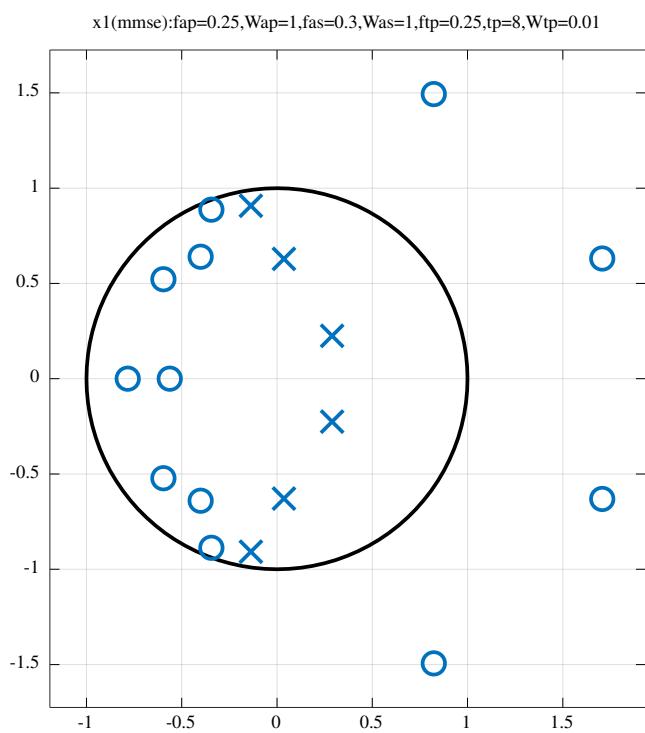

Figure 8.21: Deczky Example 1 : MMSE pole-zero plot after optimisation with Wap=1, Wtp=0.01, Was=1

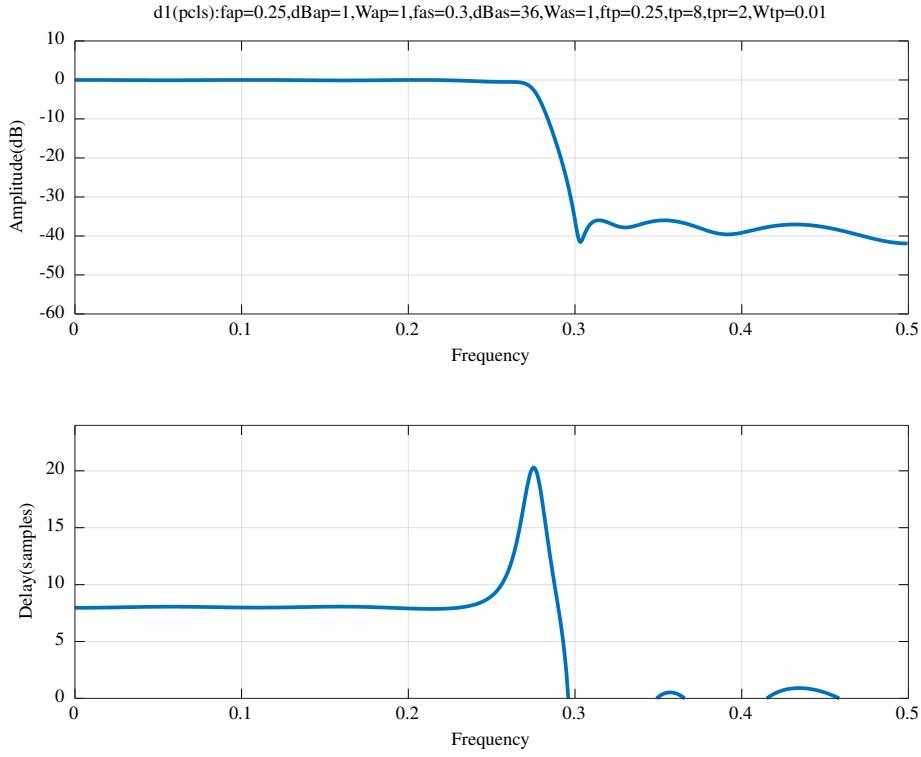

Figure 8.22: Deczky Example 1 : PCLS optimised response with dBap=1, tp=8, tpr=2, dBas=36

PCLS optimisation of Deczky's Example 1

The frequency response after PCLS optimisation is shown in Figure 8.22, the pass-band detail is shown in Figure 8.23 and the pole-zero plot is shown in Figure 8.24. The optimised filter vector is, in gain, zeros and poles form:

```
Ud1=2,Vd1=0,Md1=10,Qd1=6,Rd1=1
d1 = [ 0.0160488878, ...
        -0.7526027943, -0.7526027000, ...
        0.8710840724, 0.9144232423, 0.9846303737, 1.7151056231, ...
        1.8146808556, ...
        2.4464004488, 2.0619109995, 1.9020268555, 1.0668886635, ...
        0.3583214618, ...
        0.2855066081, 0.5991511070, 0.9345793489, ...
        0.7952509378, 1.6749350095, 1.7314450391 ]';
```

and the corresponding transfer function numerator and denominator polynomials are, respectively:

```
N1 = [ 0.0160488878, -0.0113809609, -0.0021753382, 0.0112941532, ...
        0.0142613408, -0.0365810921, -0.0197321726, 0.2034497790, ...
        0.5258530607, 0.6756040323, 0.5216936924, 0.2446900396, ...
        0.0541651450 ]';
```

and

```
D1 = [ 1.0000000000, 0.0237826342, 1.1818545578, -0.2569170045, ...
        0.3306417800, -0.1077295843, 0.0255586212 ]';
```

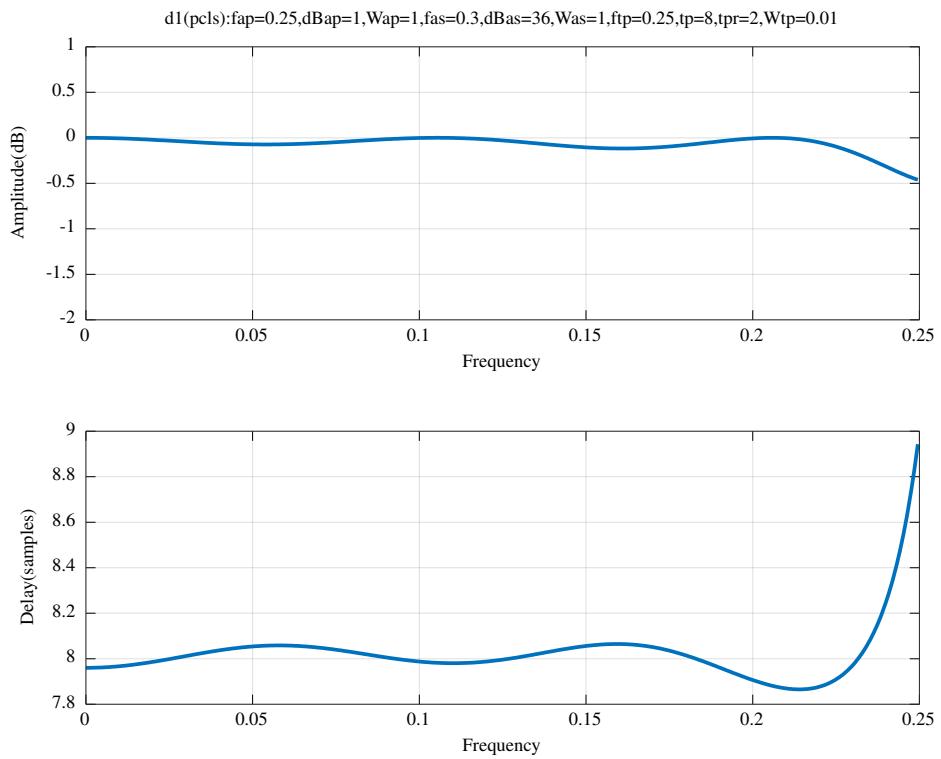

Figure 8.23: Deczky Example 1 : PCLS optimised passband response with dBap=1, tp=8, tpr=2, dBas=36

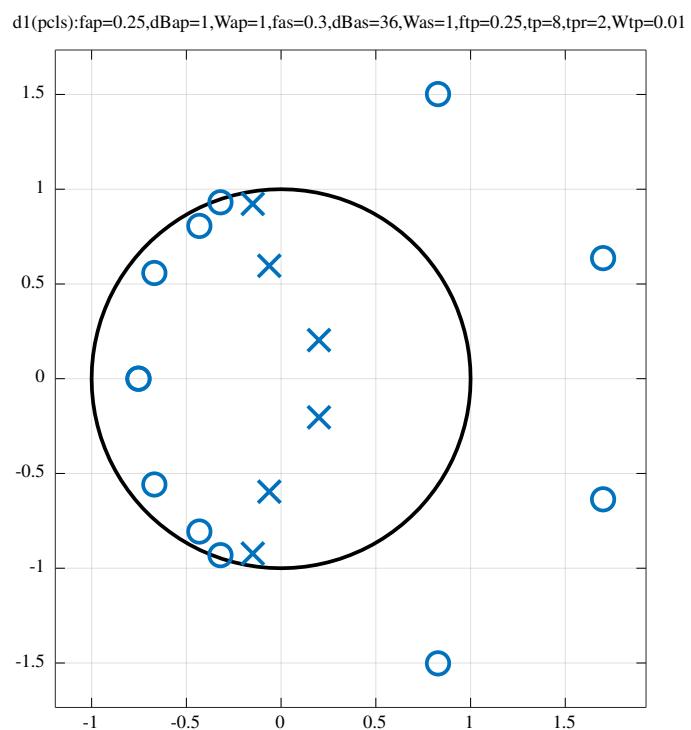

Figure 8.24: Deczky Example 1 : PCLS pole-zero plot after optimisation with dBap=1, tp=8, tpr=2, dBas=36

8.2.5 Low-pass R=2 decimation filter

The second example design is a low-pass $R = 2$ decimation filter with compensation for the zero-order hold amplitude response:

$$\begin{aligned} U &= 0 \\ V &= 0 \\ M &= 10 \\ Q &= 6 \\ R &= 2 \\ A(f) &= \begin{cases} \frac{\pi f}{\sin \pi f} & 0 < f < 0.10 \\ 0 & 0.25 < f < 0.5 \end{cases} \\ T(f) &= 8 \quad 0 < f < 0.125 \end{aligned}$$

The Octave script *decimator_R2_test.m* implements this example. The filter specification is

```
U=0 % Number of real zeros
V=0 % Number of real poles
M=10 % Number of complex zeros
Q=6 % Number of complex poles
R=2 % Denominator polynomial decimation factor
n=1000 % Frequency points across the band
tol_wise=1e-07 % Tolerance on WISE relative coef. update
tol_mmse=1e-05 % Tolerance on MMSE relative coef. update
tol_pcls=0.0004 % Tolerance on PCLS relative coef. update
ctol=1e-06 % Tolerance on constraints
fap=0.1 % Pass band amplitude response edge
dBap=0.2 % Pass band amplitude peak-to-peak ripple
Wap=1 % Pass band weight
ftp=0.125 % Pass band group delay response edge
tp=8 % Nominal filter group delay
tpr=0.008 % Pass band group delay peak-to-peak ripple
Wtp=0.25 % Pass band group delay weight
fas=0.25 % Stop band amplitude response edge
dBas=40 % Stop band minimum attenuation
Was=4 % Stop band amplitude weight
```

The initial filter is found using the *WISE* barrier function implemented in the Octave function *xInitHd* function. That filter design is itself initialised with a “guess”:

```
xi=[ 0.001, ...
[1,1,1,1,1], ...
(7:11)*pi/12, ...
0.7*[1,1,1], ...
(1:3)*pi/8]';
```

In this case the denominator decimation factor is $R = 2$ and each complex pole pair is split into 2 complex pole pairs so that the overall filter has 6 complex conjugate pole pairs. In the above listing, the first line shows the gain, and subsequent lines show, respectively, 0 real zeros, 0 real poles, the zero radiiuses for 5 conjugate pairs of zeros, the zero angles for 5 conjugate pairs of zeros, the pole radiiuses for 3 conjugate quadruples of poles and the pole angles for 3 conjugate quadruples of poles. The resulting initial response is shown in Figure 8.25.

MMSE optimisation of the low-pass R=2 decimator

After some experimentation and iteration, weights $Wap = 1$, $Was = 4$ and $Wtp = 0.25$ give the response shown in Figure 8.26 with the pass-band detail shown in Figure 8.27. The corresponding pole-zero plot is shown in Figure 8.28.

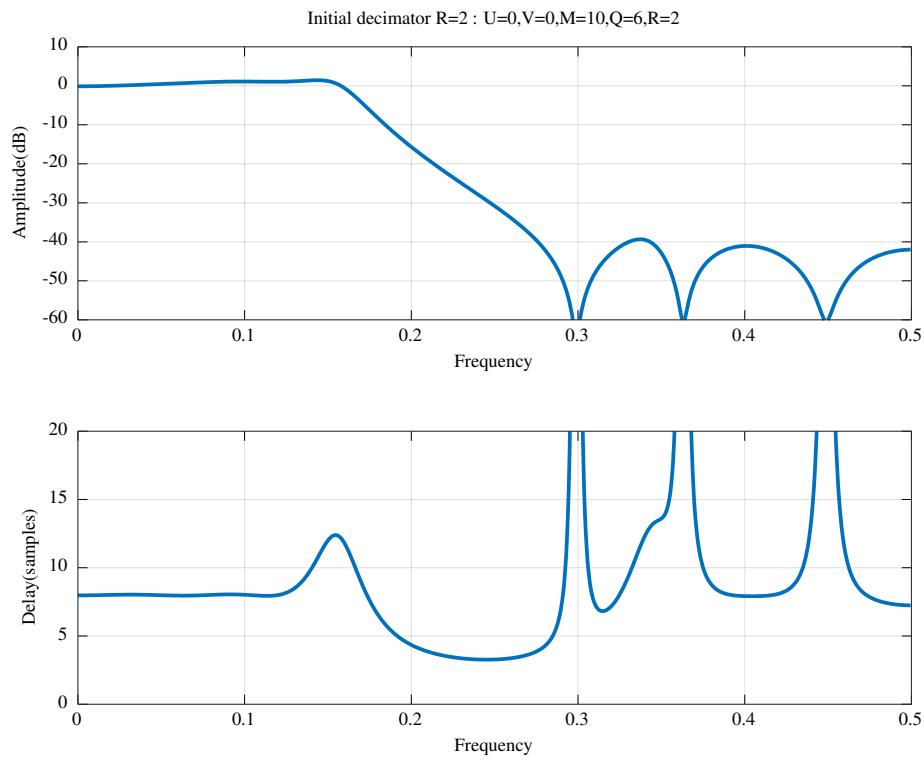

Figure 8.25: Low-pass decimator R=2 : Response for initial coefficients

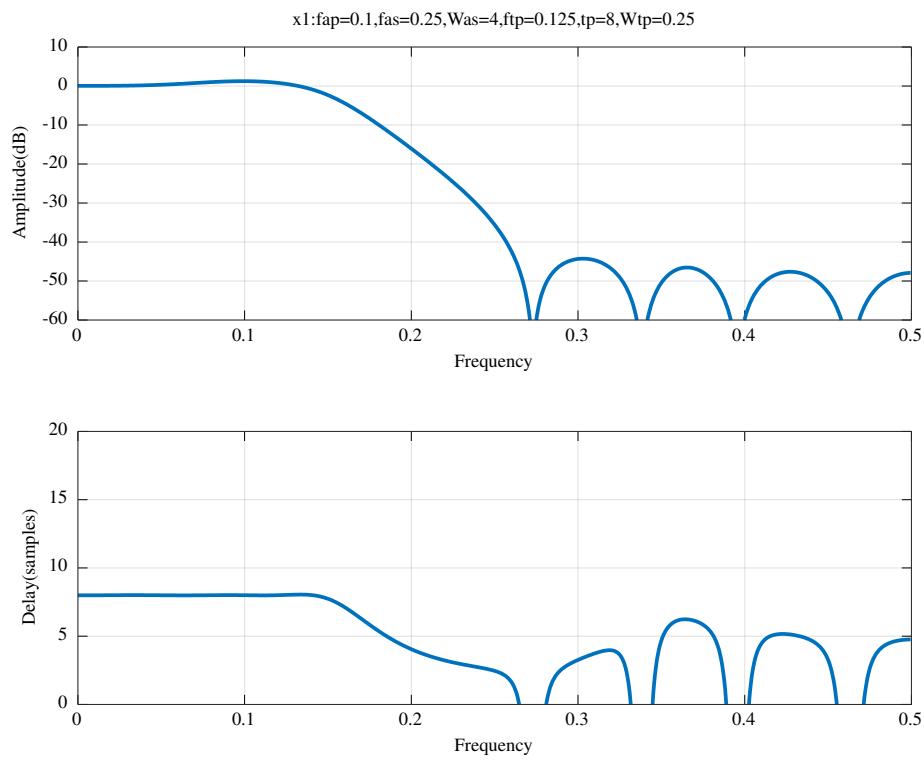

Figure 8.26: Low-pass decimator R=2 MMSE : Optimised response with Wap=1, Was=4, Wtp=0.25

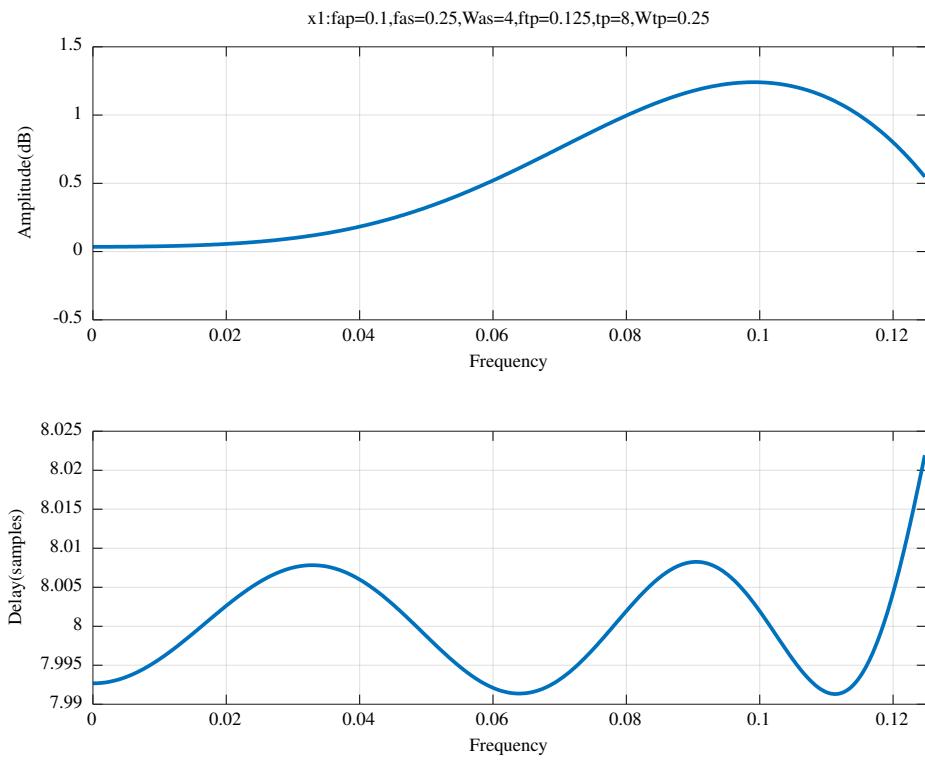

Figure 8.27: Low-pass decimator R=2 MMSE : Optimised passband response with Wap=1, Was=4, Wtp=0.25

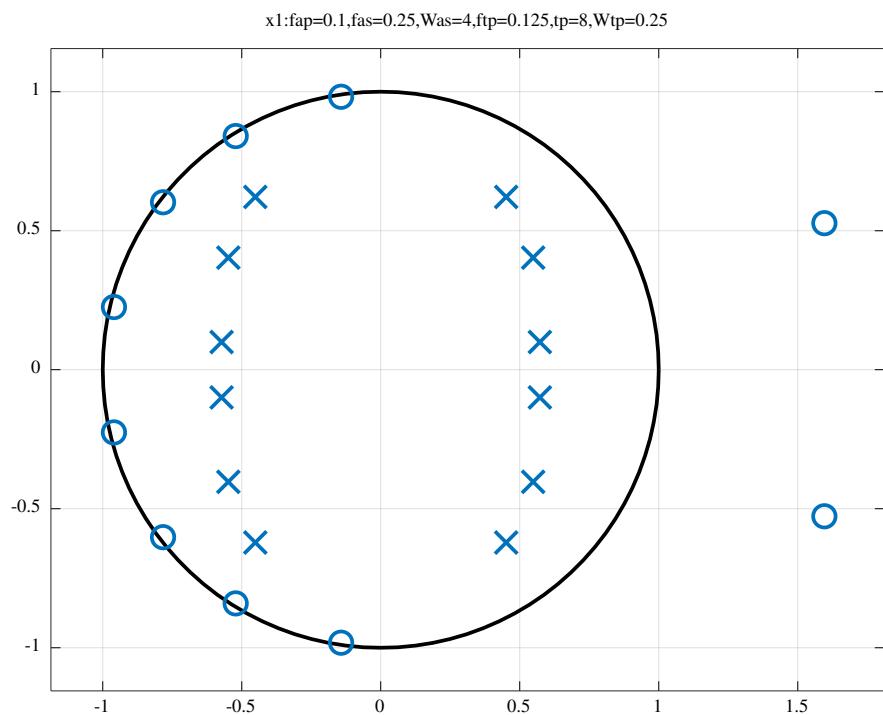

Figure 8.28: Low-pass decimator R=2 MMSE : Pole-zero plot after optimisation with Wap=1, Was=4, Wtp=0.25

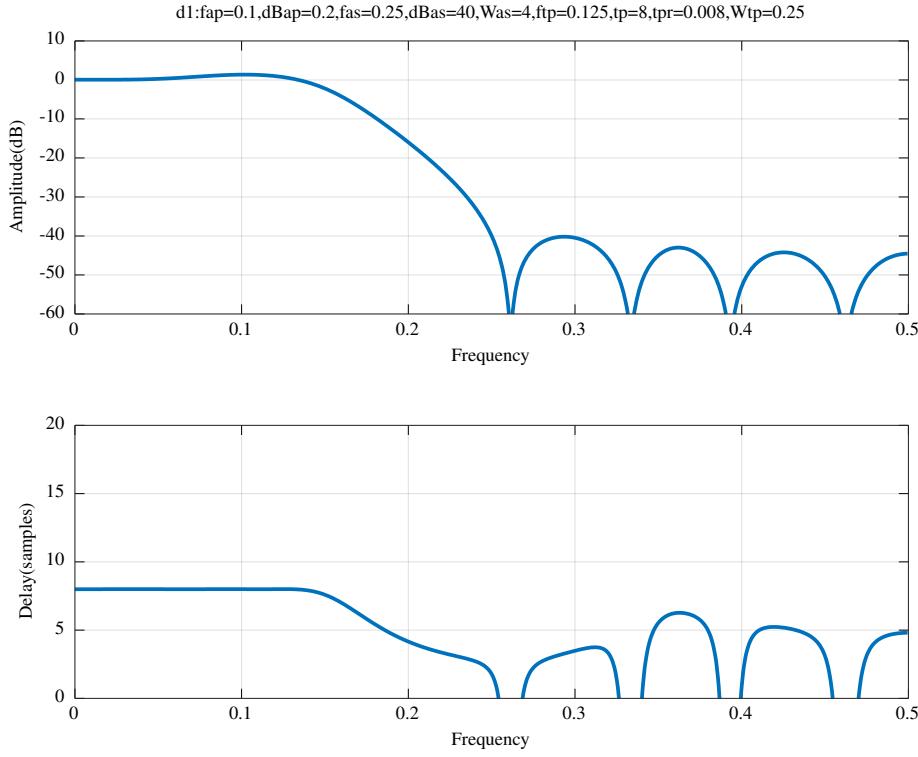

Figure 8.29: Low-pass decimator R=2 PCLS : Optimised response with $Wap=1$, $Was=4$, $Wtp=0.25$, $dBap=0.2$, $dBas=40$, $tpr=0.008$

PCLS optimisation of the low-pass R=2 decimator

Starting with the MMSE filter of Figure 8.26, the weights $Wap = 1$, $Was = 4$ and $Wtp = 0.25$ and the constraints $dBap = 0.2$, $dBas = 40$, $tp = 8$ and $tpr = 0.008$ give the response shown in Figure 8.29 with pass-band detail shown in Figure 8.30. The corresponding pole-zero plot is shown in Figure 8.31. The estimate of the optimised filter vector is, in the gain, zeros and poles form of Equation 8.2:

```
Ud1=0,Vd1=0,Md1=10,Qd1=6,Rd1=2
d1 = [ 0.0161060606, ...
        0.9868864311, 0.9886518261, 0.9893501830, 0.9937668455, ...
        1.6353073081, ...
        2.9047682215, 2.0957108462, 2.4692556321, 1.6422753294, ...
        0.3253655289, ...
        0.2895580115, 0.4476251767, 0.5685648808, ...
        0.1233765834, 1.2773575155, 1.8742906004 ]';
```

and the corresponding transfer function numerator and denominator polynomials (found with Octave function $x2tf$) are, respectively:

```
N1 = [ 0.0161060606, 0.0241685094, -0.0100507974, -0.0688125875, ...
        -0.0735733782, 0.0253325896, 0.1796304283, 0.2782233580, ...
        0.2526071915, 0.1407143436, 0.0396349459 ]';
```

and

```
D1 = [ 1.0000000000, 0.0000000000, -0.4938226426, 0.0000000000, ...
        0.4729884112, 0.0000000000, -0.2591986855, 0.0000000000, ...
        0.1102722084, 0.0000000000, -0.0385348311, 0.0000000000, ...
        0.0054307554 ]';
```

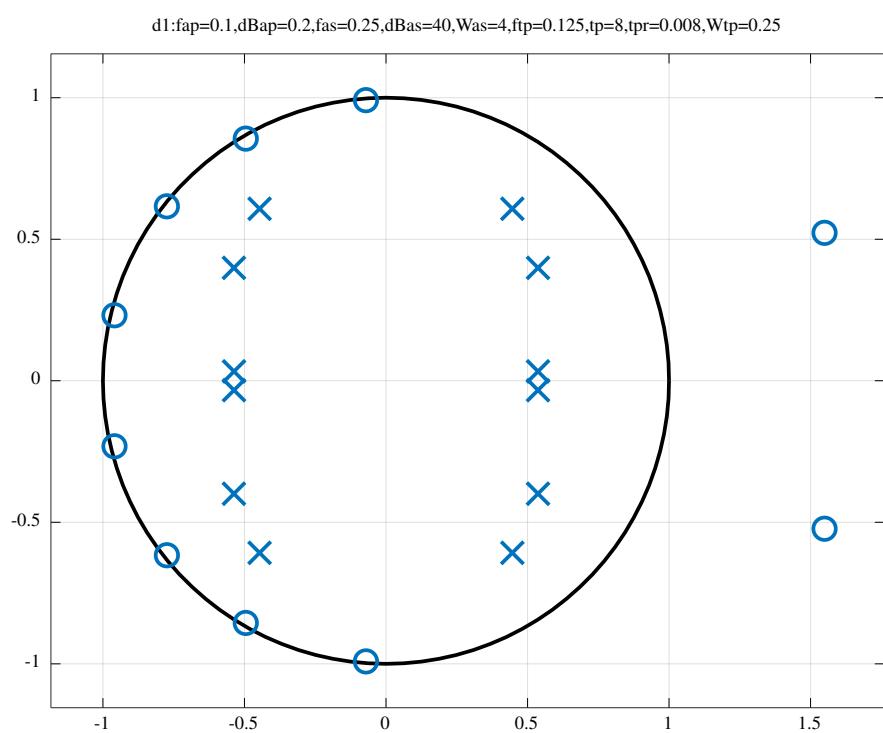

Figure 8.31: Low-pass decimator R=2 PCLS : Optimised pole-zero plot with Wap=1, Was=4, Wtp=0.25, dBap=0.2, dBas=40, tpr=0.008

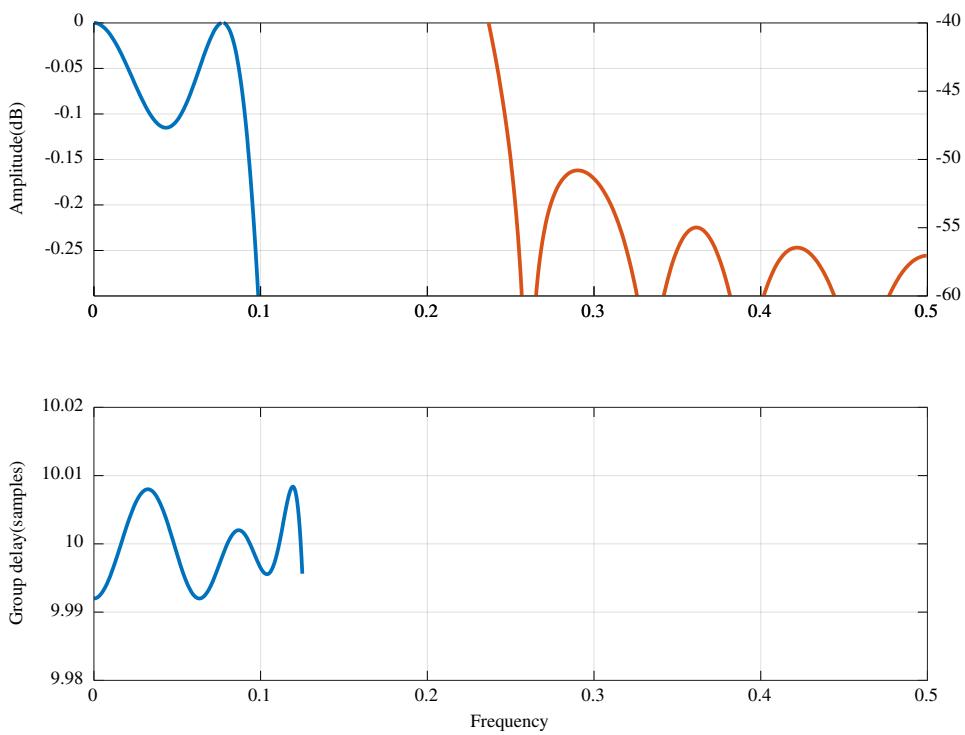

Figure 8.32: Alternative low-pass decimator $R=2$: PCLS optimised response with $W_{ap}=1$, $W_{as}=5$, $W_{tp}=0.1$, $dB_{ap}=0.35$, $dB_{as}=50$, $tp=10$, $tpr=0.016$

An alternative implementation of the low-pass $R=2$ decimator

The Octave script *decimator_R2_alternate_test.m* designs an alternative implementation of an $R = 2$ decimation low-pass filter with a flat pass-band amplitude response. The alternative filter specification is:

```

U=0 % Number of real zeros
V=0 % Number of real poles
M=12 % Number of complex zeros
Q=6 % Number of complex poles
R=2 % Denominator polynomial decimation factor
n=1000 % Frequency points across the band
tol_wise=1e-07 % Tolerance on WISE relative coef. update
tol_mmse=1e-05 % Tolerance on MMSE relative coef. update
tol_pcls=0.0005 % Tolerance on PCLS relative coef. update
ctol=1e-07 % Tolerance on constraints
fap=0.1 % Pass band amplitude response edge
dBap=0.35 % Pass band amplitude peak-to-peak ripple
Wap=1 % Pass band weight
ftp=0.125 % Pass band group delay response edge
tp=10 % Nominal filter group delay
tpr=0.016 % Pass band group delay peak-to-peak ripple
Wtp=0.1 % Pass band group delay weight
fas=0.25 % Stop band amplitude response edge
dBas=50 % Stop band minimum attenuation
Was=5 % Stop band amplitude weight

```

Figure 8.32 shows the response of the resulting filter.

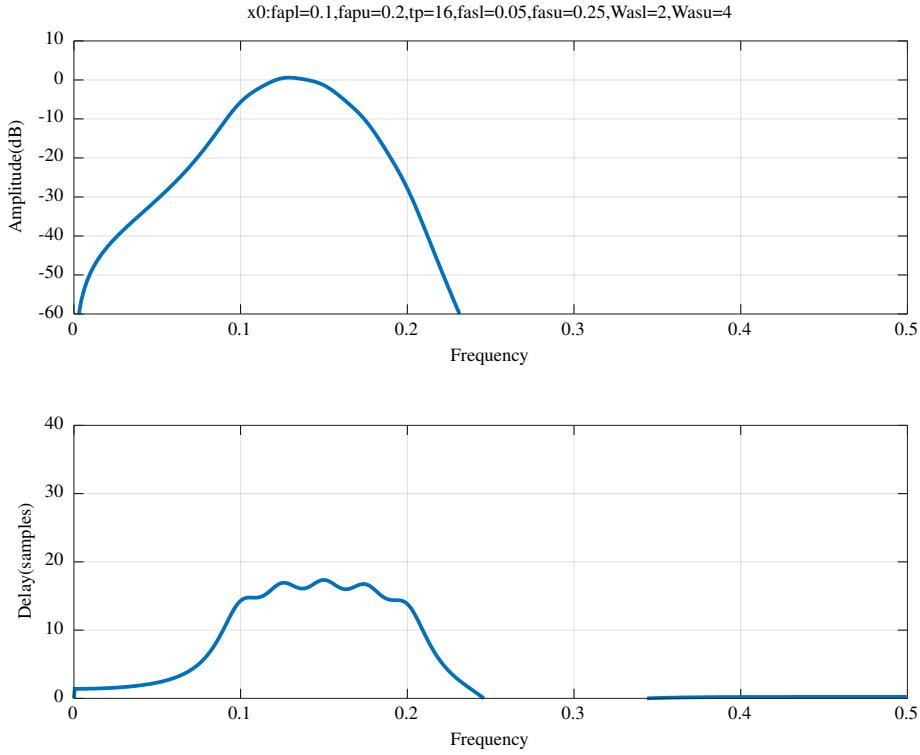

Figure 8.33: IIR band-pass R=2 decimation filter : response of the initial filter

8.2.6 Band-pass R=2 decimation filter

The fourth example design is an $R = 2$ decimation band-pass filter. The amplitude response pass-band edges are at frequencies $0.1f_s$ and $0.2f_s$. The amplitude response stop-band edges are at frequencies $0.05f_s$ and $0.25f_s$. The pass-band group-delay specification is 16 samples with band edges at frequencies $0.09f_s$ and $0.21f_s$. The Octave script *iir_sqp_slb_bandpass_test.m* implements this example. The *sqp* loop is implemented by the Octave function *iir_slb*. The initial filter was “guesstimated” and has a pole-zero specification of $U = 2$, $V = 0$, $M = 18$, $Q = 10$ and $R = 2$:

```
U=2,V=0,M=18,Q=10,R=2
x0=[ 0.00005, ...
1, -1, ...
0.9*ones(1,6), [1 1 1], ...
(11:16)*pi/20, (7:9)*pi/10, ...
0.81*ones(1,5), ...
(4:8)*pi/10 ]';
```

In the above listing, the first line shows the gain, and subsequent lines show, respectively, 2 real zeros, 0 real poles, the zero radiiuses for 9 conjugate pairs of zeros, the zero angles for 9 conjugate pairs of zeros, the pole radiiuses for 5 conjugate pairs of poles and the pole angles for 5 conjugate pairs of poles. In this case the denominator decimation factor is $R = 2$ and each complex pole pair is split into 2 complex pole pairs so that the overall filter has 10 complex conjugate pole pairs. The response of the initial filter is shown in Figure 8.33.

MMSE optimisation of the band-pass R=2 decimator

First the initial filter is passed through *iir_sqp_mmse* with amplitude response pass-band weight $Wap = 1$, amplitude response lower and upper stop-band weights $Wasl = 2$ and $Wasu = 4$, respectively, and group-delay response pass-band weight $Wtp = 1$. The response of the MMSE-optimised filter is shown in Figure 8.34 with pass-band detail shown in Figure 8.35. The corresponding pole-zero plot is shown in Figure 8.36.

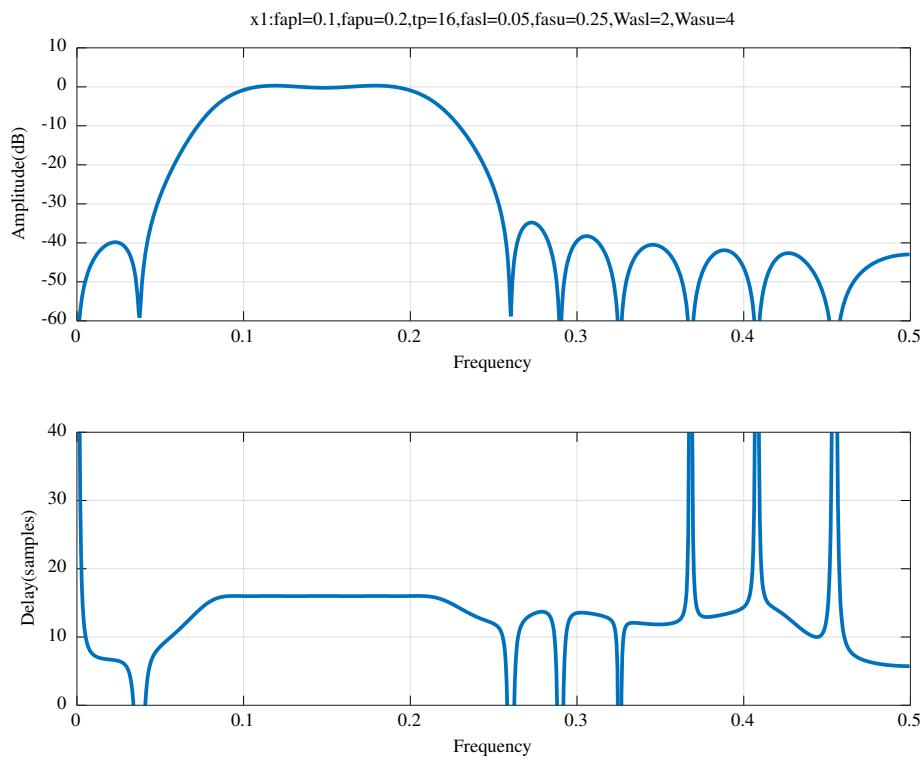

Figure 8.34: IIR band-pass R=2 decimation filter with delay tp=16 samples : response of the filter after MMSE optimisation

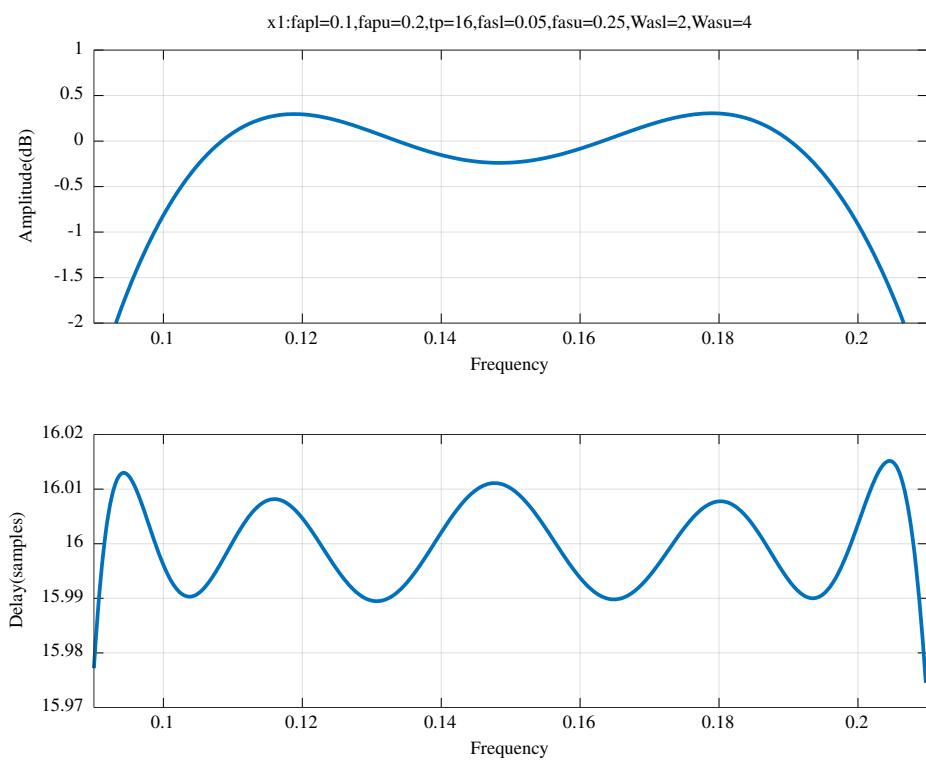

Figure 8.35: IIR band-pass R=2 decimation filter with delay tp=16 samples : passband response of the filter after MMSE optimisation

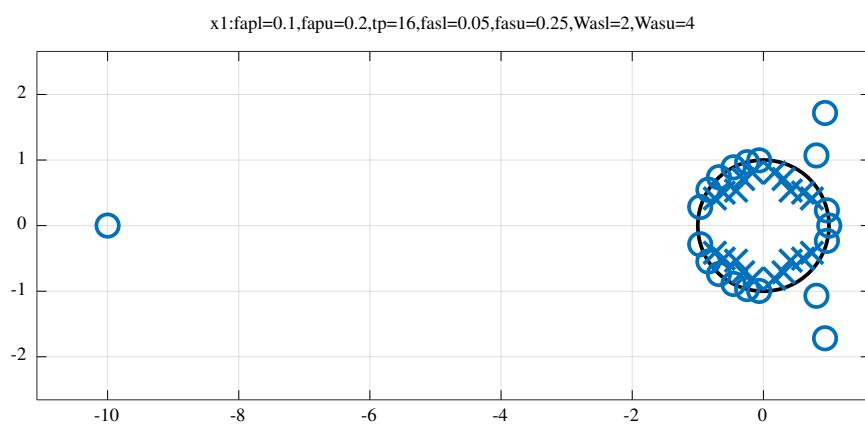

Figure 8.36: IIR band-pass R=2 decimation filter with delay tp=16 samples : pole-zero plot of the filter after MMSE optimisation

PCLS optimisation of the band-pass R=2 decimator

Next, the filter designed in Section 8.2.6 is passed through *iir_slb* for PCLS optimisation with $Wtp = 1$, $tpr = 0.08$ samples, $dBap = 1$ and $dBas = 35$. The response of the resulting filter is shown in Figure 8.37 with pass-band detail shown in Figure 8.38. The corresponding pole-zero plot is shown in Figure 8.39. The estimate of the optimised filter vector is, in the gain, zeros and poles form of Equation 8.2:

```
Ud1=2,Vd1=0,Md1=18,Qd1=10,Rd1=2
d1 = [ 0.0119656597, ...
-0.9514948923, 0.9678046406, ...
0.9817229037, 0.9818077994, 0.9829835592, 0.9835724353, ...
0.9847919915, 0.9926792987, 0.9951005693, 1.3534382786, ...
1.4188004701, ...

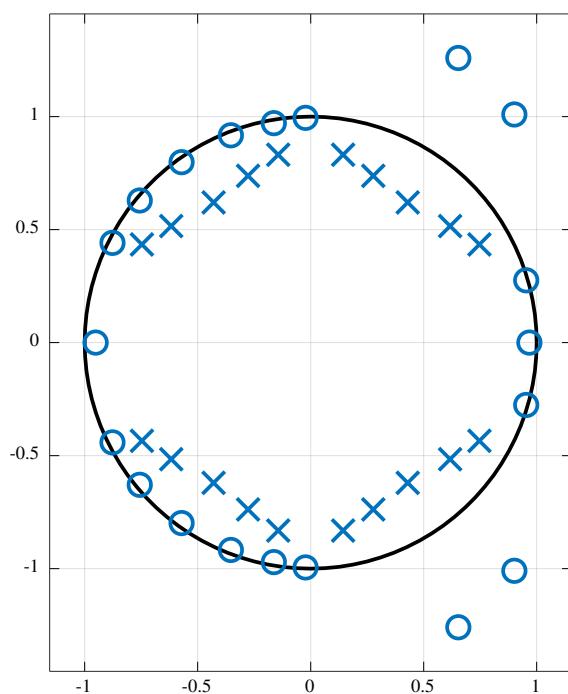

Figure 8.39: IIR band-pass R=2 decimation filter with delay tp=16 samples : pole-zero plot of the filter after PCLS optimisation

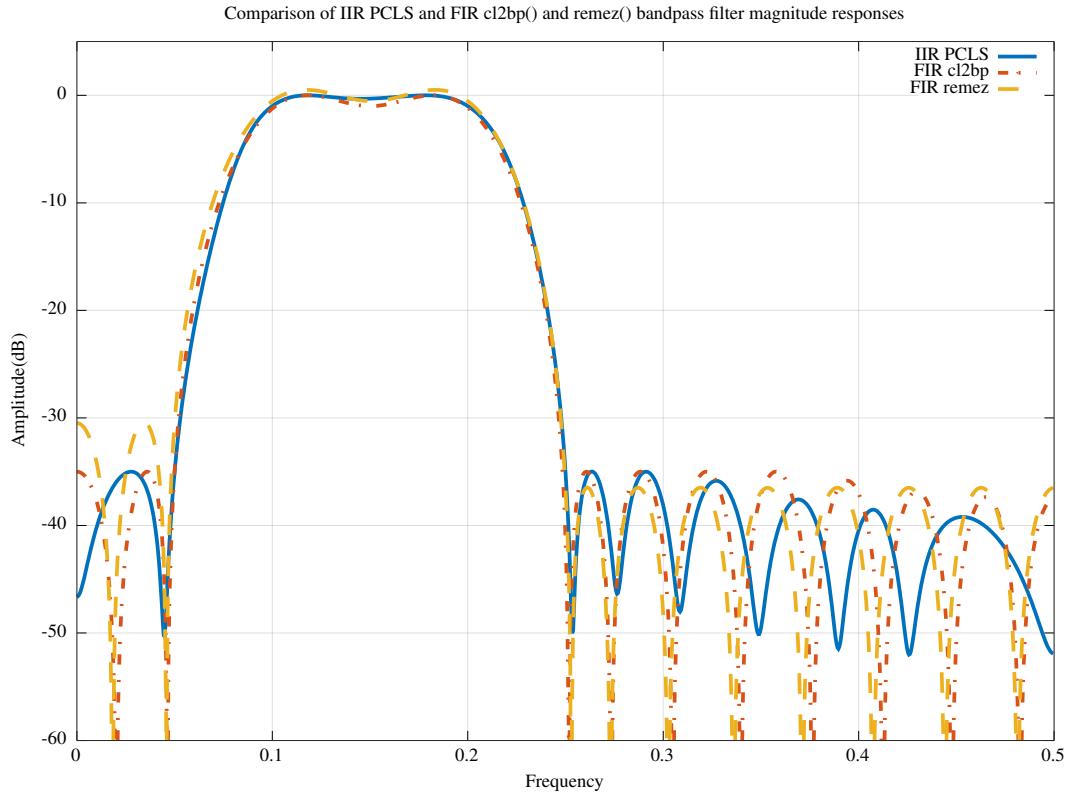

Figure 8.40: Comparison of the magnitude responses of the bandpass PCLS IIR filter and FIR filters designed by *cl2bp* and *remez*

Comparison with FIR band-pass filter designs

For comparison, an FIR filter was designed with the *remez* Octave function:

```
N=1+U+V+M+Q;
brz=remez(N-1,2*[0 fasl fapl fasu 0.5],[0 0 1 1 0 0], ...
           [Was1 Wap Wasu],'bandpass');
```

Similarly, an FIR filter was designed with Selesnick's Octave function, *cl2bp*. The nominal passband has been adjusted to provide a similar response to the *remez* and PCLS IIR filters. The specifications of the *cl2bp* filter design are:

```
wl=fapl*2*pi*0.8;
wu=fapu*2*pi*1.1;
up=10.^([-dBas, 0, -dBas]/20);
lo=[-1,1,-1].*10.^([-dBas, -dBap, -dBas]/20);
Ccl=floor(N/2)

```

The FIR filter designs are linear phase with filter length set to the number of coefficients of the IIR PCLS filter. Hence the group delay of the FIR filters is 15 samples compared to 16 samples for the IIR PCLS filter.

The responses of the FIR filters and the IIR PCLS filter are compared in Figure 8.40.

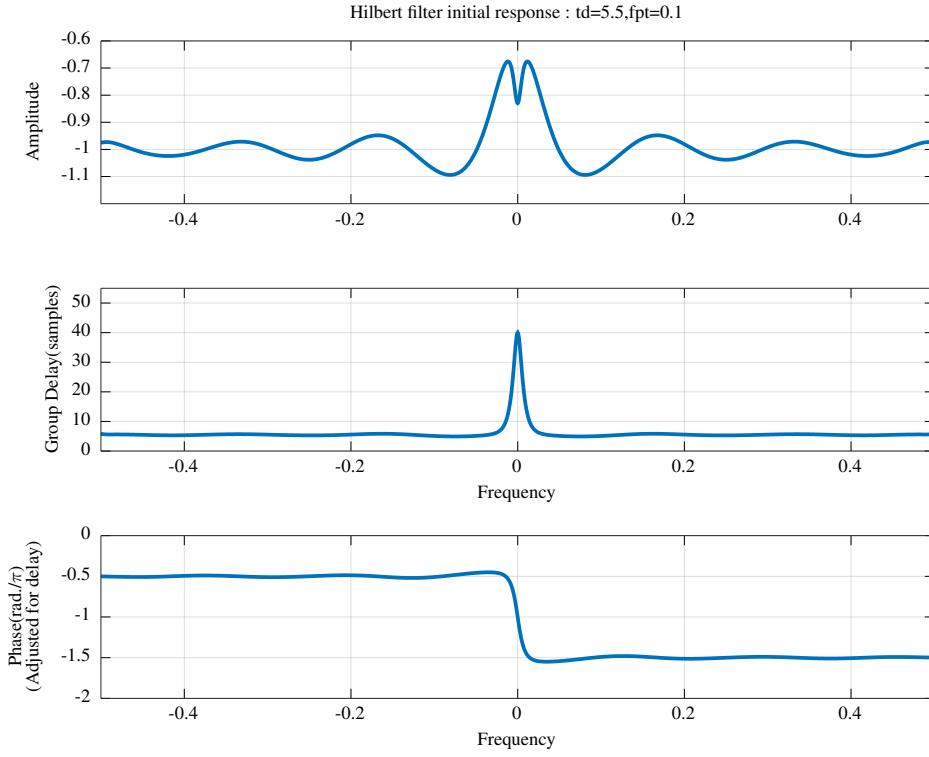

Figure 8.41: Response of the initial Hilbert filter designed by *tarczynski_hilbert_test.m* with $R = 2$ and $t_d = 5.5$

8.2.7 Hilbert transform R=2 decimation filter

A Hilbert transform filter[11, p.118] has the transfer function

$$H_d(\omega) = -i\text{sign}(\omega) e^{-i\omega t_d}$$

The Octave script *iir_sqp_slb_hilbert_test.m* designs a Hilbert transform filter with $U = 7$, $V = 2$, $M = 4$, $Q = 4$, $R = 2$ and the group-delay of the filter is $t_d = \frac{U+M}{2} = 5.5$ samples. An initial filter was designed by the method of Tarczynski et. al. with the Octave script *tarczynski_hilbert_test.m*. The initial filter coefficients are, in gain-pole-zero form:

```
Ux0=7, Vx0=2, Mx0=4, Qx0=4, Rx0=2
x0 = [ -0.0579063991, ...
-1.8392367865, -0.9615145734, -0.6828573729, -0.1324575259, ...
0.4144283665, 0.8764702854, 1.0642620029, ...
-0.2223068711, 0.9249475286, ...
1.6409666558, 1.7962277114, ...
1.0002164452, 2.0743525933, ...
0.2451944963, 0.3860183248, ...
1.6840129288, 0.1456661035 ]';
```

The amplitude, group delay and phase response of the initial filter, as calculated by the Octave functions *iirA*, *iirT* and *iirP* are shown in Figure 8.41. The script defines a phase response “don’t-care” transition band of $f_{pt} = \pm 0.05$ about $\omega = 0$. Similarly, the group delay transition band is $f_{pt} = \pm 0.075$. Note that the *iirA* function can return a negative amplitude if, as in this case, the gain coefficient is negative. I do this so that $\frac{\partial A}{\partial K}$ is well-defined at $K = 0$ (since the absolute value of K is not differentiable at 0). Consequently, the phase returned by the *iirP* function does not include the sign of the gain coefficient. The phase response, relative to π , is shown adjusted for the group-delay by adding ωt_d where ω is the angular frequency vector for which the response is calculated.

MMSE optimisation of the Hilbert transform R=2 decimator

Figure 8.42 shows the response after MMSE optimisation of the initial filter. The relative weights of the amplitude, group delay and phase errors were $W_{ap} = 1$, $W_{tp} = 0.00001$ and $W_{pp} = 0.001$ respectively. The desired PCLS constraints are superimposed on the figure. The *iirP* function does not calculate the Hessian of the phase response. In the previous examples only the diagonal of the Hessian matrix of the error response is used to initialise the SQP loop. In this case the diagonal of the Hessian of the phase response is approximated with the Octave function *iirP_hessP_DiagonalApprox.m*.

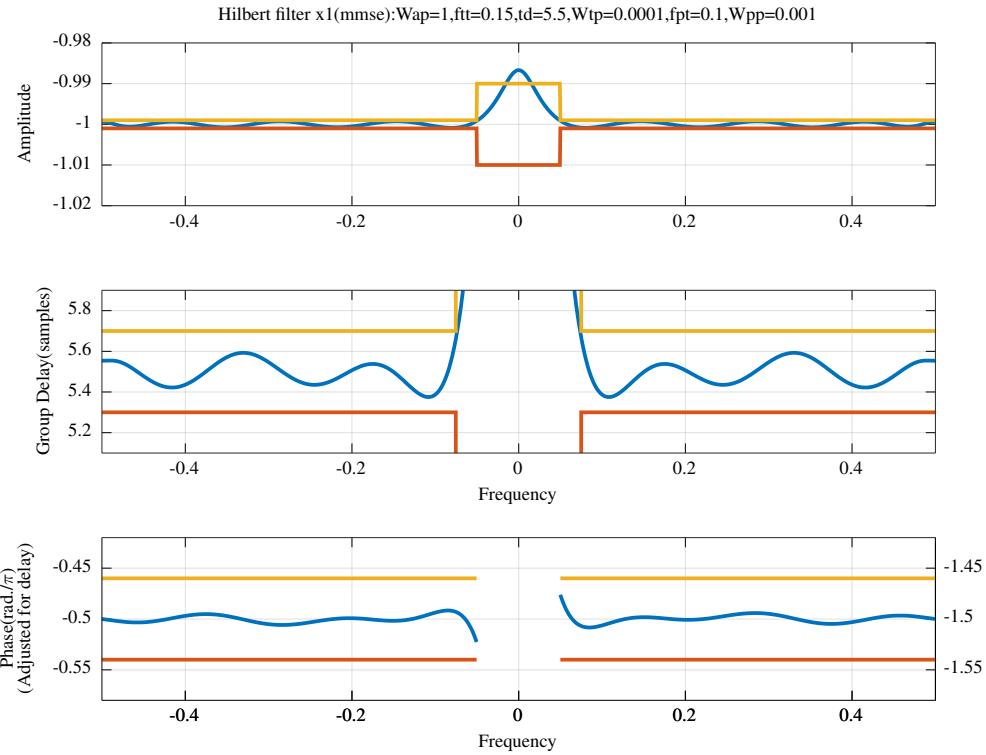

Figure 8.42: Response of the Hilbert filter after MMSE optimisation with $R = 2$, $W_{ap} = 1$, $W_{tp} = 0.00001$ and $W_{pp} = 0.001$

PCLS optimisation of the Hilbert transform R=2 decimator

Figure 8.43 shows the response after PCLS optimisation of the MMSE optimised filter of Figure 8.42. Figure 8.44 shows the pole-zero plot for the PCLS optimised filter. The peak-to-peak amplitude, group delay and phase ripple outside the transition band are $A_r = 0.002$, $t_{dr} = 0.4$ and $p_r = 0.1\frac{\pi}{2}$ respectively. The PCLS optimised filter coefficients are, in gain-pole-zero form

```
Ud1=7,Vd1=2,Md1=4,Qd1=4,Rd1=2
d1 = [ -0.0123415723, ...
       -2.4098917209, -0.8228995524, -0.2738944549, -0.1631693463, ...
       0.3067276080, 0.4596602730, 1.2140262062, ...

```

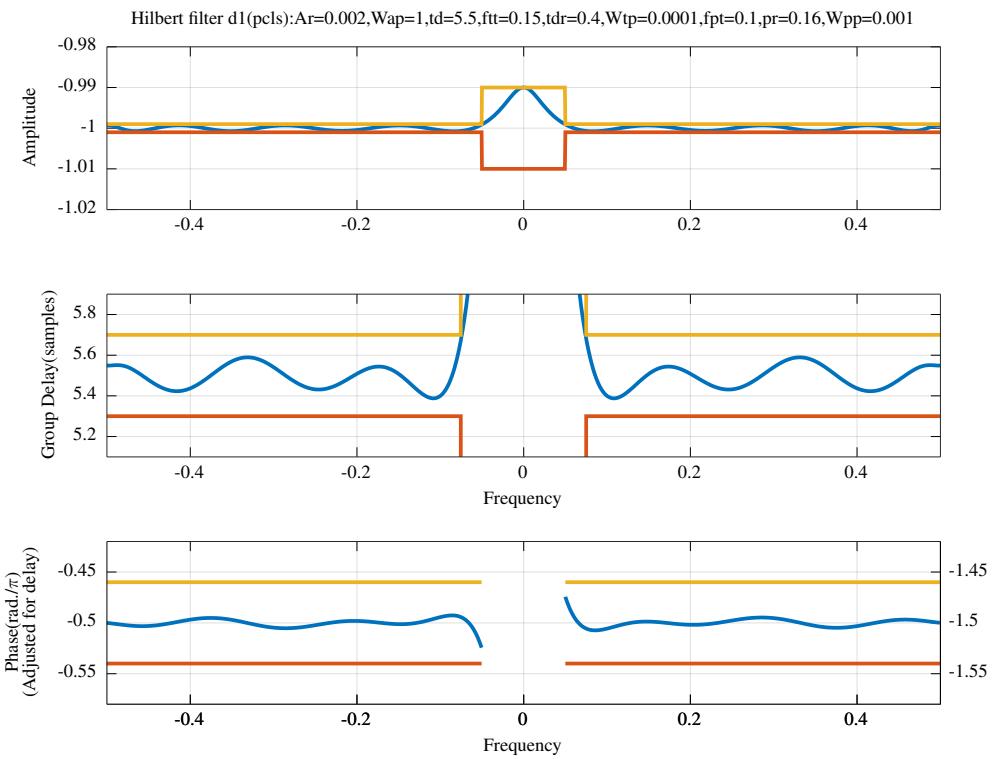

Figure 8.43: Response of the Hilbert filter after PCLS optimisation with $R = 2$, $A_r = 0.002$, $t_{dr} = 0.4$ and $p_r = 0.16\frac{\pi}{2}$

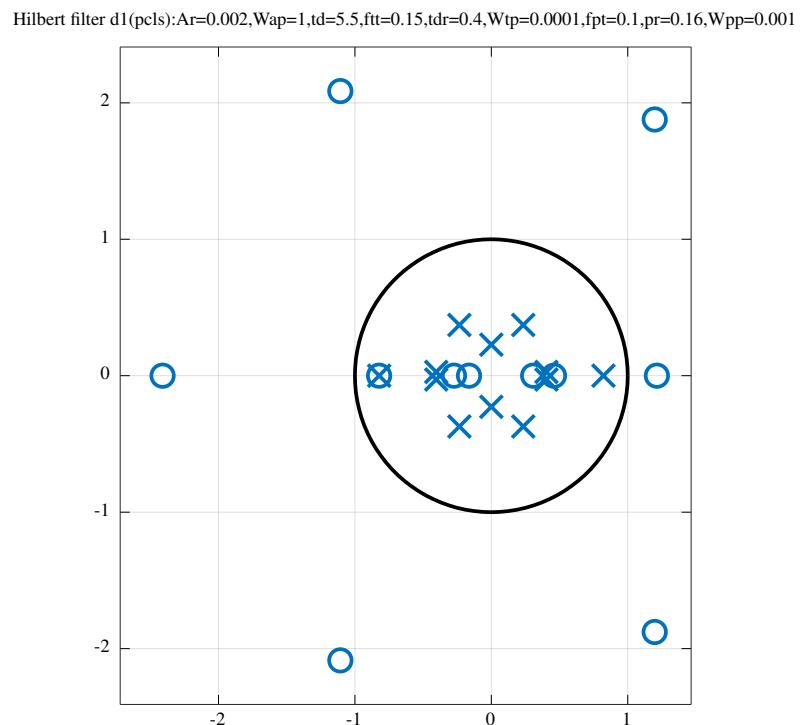

Figure 8.44: Pole-zero plot of the Hilbert filter after PCLS optimisation with $R = 2$, $A_r = 0.002$, $t_{dr} = 0.4$ and $p_r = 0.16\frac{\pi}{2}$

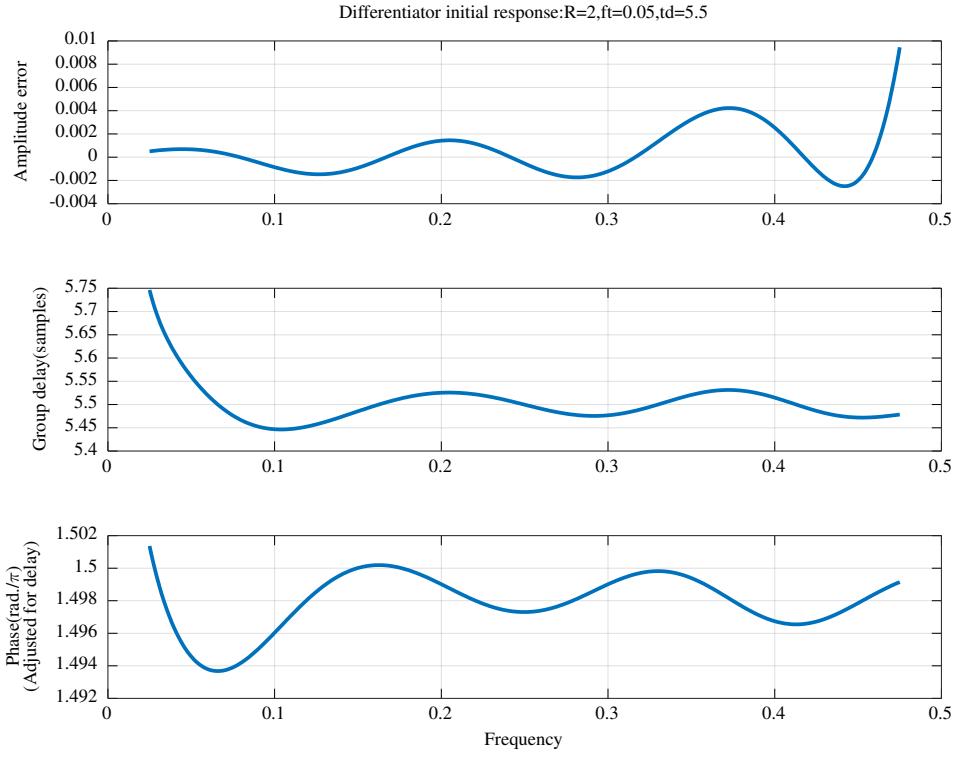

Figure 8.45: Response of the initial $R=2$ differentiator filter calculated by $iirA()$, $iirT()$ and $iirP()$

8.2.8 R=2 differentiator filter

A differentiator filter has transfer function $H_d(\omega) = \frac{i\omega}{\pi} e^{-i\omega t_d}$. The Octave script `iir_sqp_slb_differentiator_test.m` designs a differentiator filter with $U = 4$, $V = 2$, $M = 4$, $Q = 2$, $R = 2$ and the group-delay of the filter is $t_d = 5.5$ samples. An initial filter was designed by the method of Tarczynski *et al* with the Octave script `tarczynski_differentiator_test.m`. That script designs the transfer function polynomials of the filter and it seems to consistently find cancelling pairs of zeros and poles. The script gives a filter with $U = 6$, $V = 4$, $M = 6$, $Q = 2$, $R = 2$ and a group-delay of $t_d = \frac{U+M-1}{2} = 5.5$. After removing the poles and zeros of this filter that almost cancel, the initial filter coefficients used in this example are, in gain-pole-zero form:

```
Ux0=4, Vx0=2, Mx0=4, Qx0=2, Rx0=2
x0 = [ -0.0033301625, ...
        -0.2476976266, 0.3309893840, 1.0036639004, 2.4432889231, ...
        -0.1370501745, 0.2283263247, ...
        2.5725431250, 2.6080098957, ...
        2.3928644449, 1.2330172843, ...
        0.1584621214, ...
        1.5131179592 ]';
```

The initial filter amplitude, group delay and phase responses, as calculated by the Octave functions $iirA$, $iirT$ and $iirP$, are shown in Figure 8.45. The script defines a “don’t-care” transition band of $ft = \pm 0.05$ at $\omega = 0$ and 0.5 . The phase response shown is adjusted for the group-delay by adding $w * td$ where w is the angular frequency vector for which the response is calculated. As for the Hilbert filter example, the gain coefficient is negative, cancelling out the nominal phase of $\frac{3\pi}{2}$.

MMSE optimisation of the R=2 differentiator filter

Figure 8.46 shows the response after MMSE optimisation of the initial filter. The relative weights of the amplitude, group delay and phase error are $W_{ap} = 1$, $W_{tp} = 0.001$ and $W_{pp} = 0.1$ respectively.

PCLS optimisation of the R=2 differentiator filter

Figure 8.47 shows the response after PCLS optimisation of the MMSE optimised filter of Figure 8.46. Figure 8.48 shows the pole-zero plot for the PCLS filter. The peak-to-peak amplitude, group delay and phase ripple outside the transition bands are

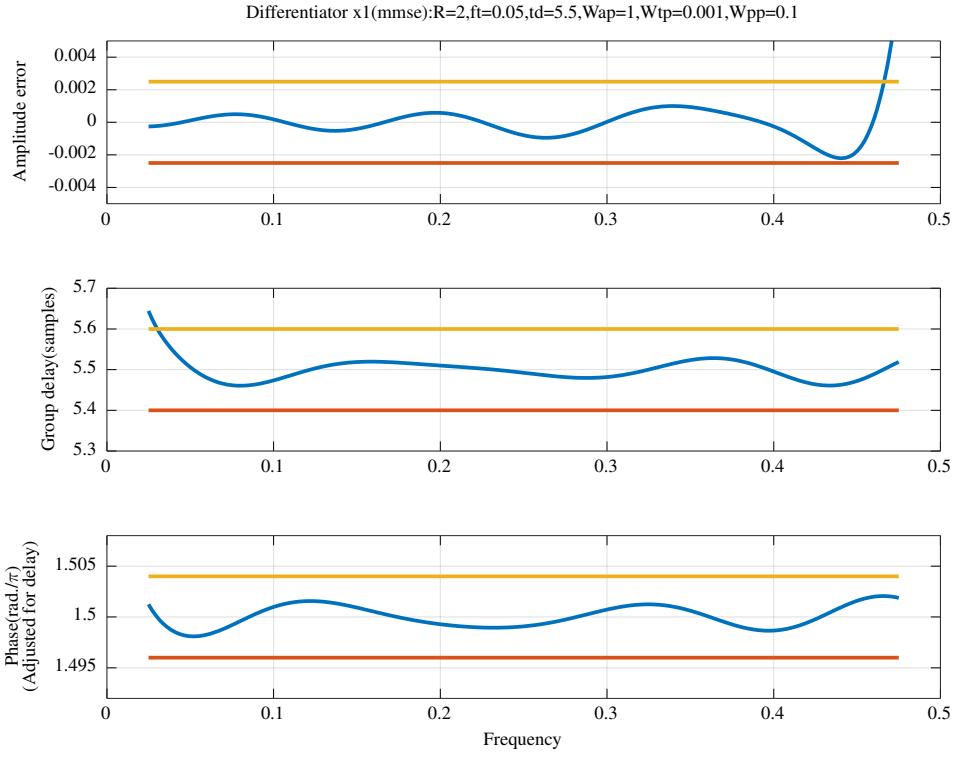

Figure 8.46: Response error of the $R=2$ differentiator filter after MMSE optimisation with $W_{ap} = 1$, $W_{tp} = 0.001$ and $W_{pp} = 0.1$

$A_r = \pm 0.0025$, $t_{dr} = \pm 0.1$ samples and $p_r = \pm 0.004\pi$ respectively. The PCLS optimised filter coefficients are, in gain-pole-zero form:

```
Ud1=4,Vd1=2,Md1=4,Qd1=2,Rd1=2
d1 = [ -0.0016812678, ...
        -0.3003313541, 0.3884097148, 1.0012842019, 3.0522524349, ...
        -0.1970013900, 0.3156558856, ...
        2.8133581352, 3.0077313852, ...
        2.3534422035, 1.1643928787, ...
        0.2340107359, ...
        1.5145819835 ]';
```

and in transfer function form the numerator and denominator polynomials are, respectively

```
N1 = [ -0.0016812678, 0.0042903493, -0.0071263976, 0.0145505533, ...
        -0.0431647393, 0.4023345251, -0.3981831469, -0.0142854191, ...
        0.0429174203 ]';
```

and

```
D1 = [ 1.0000000000, 0.0000000000, -0.1449501609, 0.0000000000, ...
        -0.0043035248, 0.0000000000, -0.0048624550, 0.0000000000, ...
        -0.0034052950 ]';
```

As a check, Figure 8.49 shows the response of the PCLS optimised filter calculated with the Octave *freqz* and *grpdelay* functions. In this case the amplitude response is plotted as a proportion of the frequency.

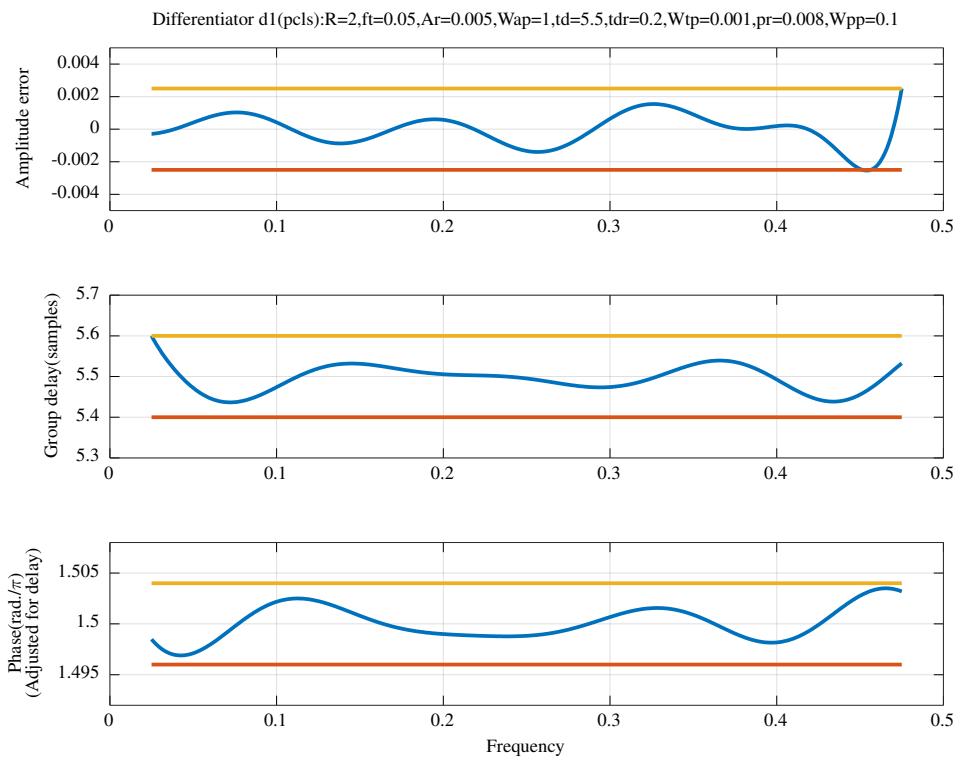

Figure 8.47: Response of the R=2 differentiator filter after PCLS optimisation with $A_r = \pm 0.002$, $t_{dr} = \pm 0.1$ and $p_r = \pm 0.004\pi$

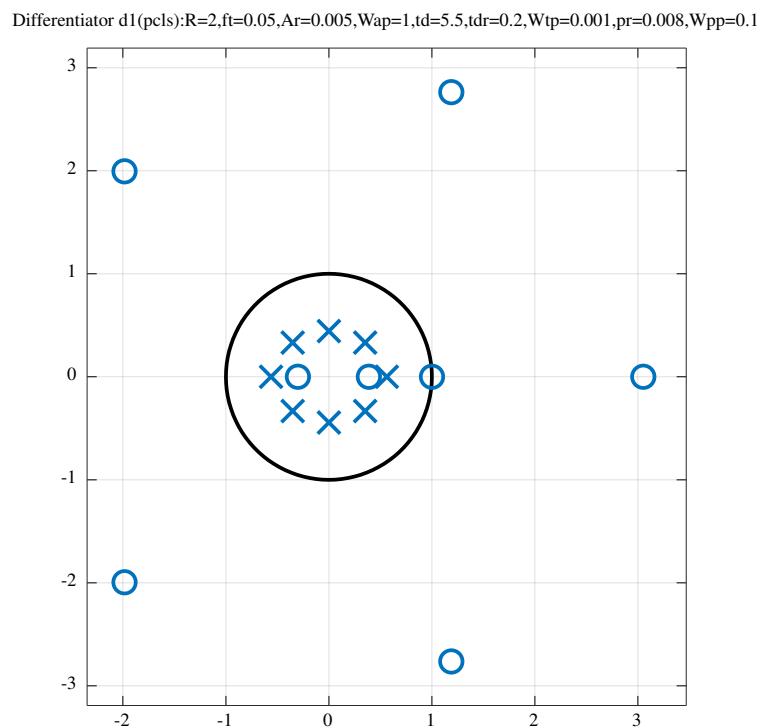

Figure 8.48: Pole-zero plot of the R=2 differentiator filter after PCLS optimisation with $A_r = \pm 0.002$, $t_{dr} = \pm 0.1$, $p_r = \pm 0.004\pi$, $W_{ap} = 1$, $W_{tp} = 0.001$ and $W_{pp} = 0.1$

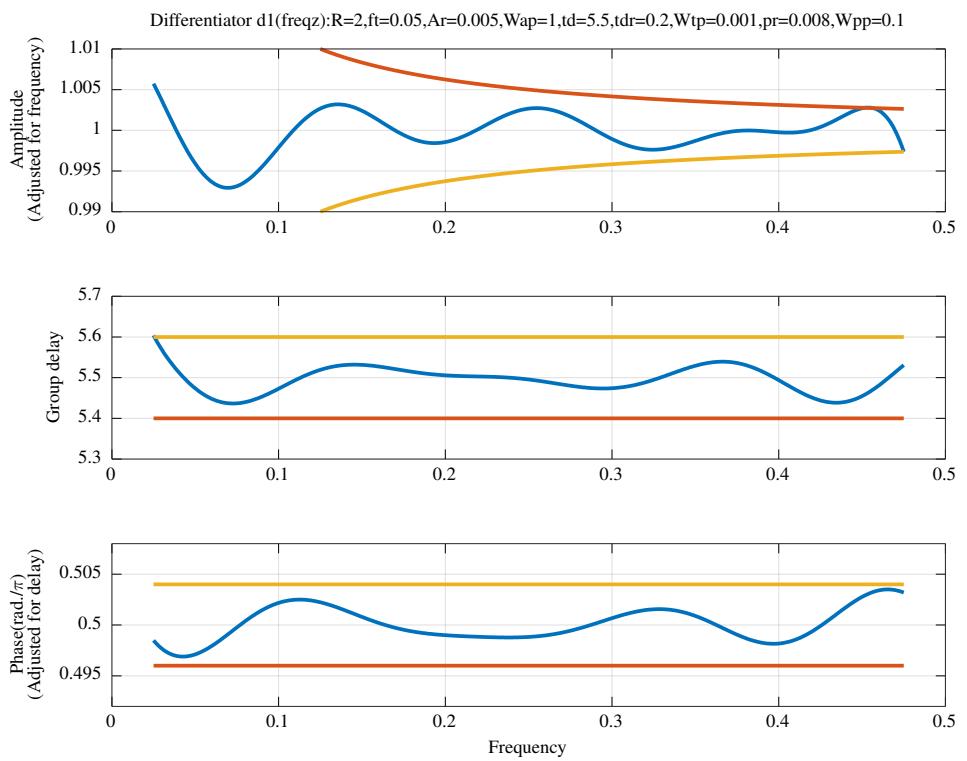

Figure 8.49: Response of the $R=2$ differentiator filter after PCLS optimisation calculated with *freqz* and *grpdelay*. The amplitude response is plotted as a proportion of the frequency.

8.2.9 Pink noise filter

Pink noise has equal noise power per octave. A pink noise filter has transfer function $H_d(\omega) = \frac{K}{\sqrt{\omega}} e^{-i\omega t_d}$ where K is a constant and t_d is the nominal filter group delay. The Octave script *iir_sqp_slb_pink_test.m* designs an 11th order IIR pink noise filter with the specification:

```
n=1000 % Frequency points across the band
tol_mmse=2e-05 % Tolerance on coef. update (MMSE pass)
tol_pccls=2e-05 % Tolerance on coef. update (PCCLS pass)
ctol=2e-05 % Tolerance on constraints
fat=0.005 % Amplitude transition band width
AdBr=0.2 % Relative amplitude peak-to-peak ripple (dB)
Wap=10 % Amplitude weight
fft=0.025 % Group delay transition band width
tp=4.77 % Nominal filter group delay
tpr=0.02 % Filter group delay peak-to-peak ripple
Wtp=1 % Filter group delay weight
U=3 % Number of real zeros
V=1 % Number of real poles
M=8 % Number of complex zeros
Q=10 % Number of complex poles
R=1 % Denominator polynomial decimation factor
```

The script defines a “don’t-care” transition band from $f = 0$ to $fat = 0.005$ for the amplitude response and $fft = 0.02$ for the group delay response. An initial filter was designed by the method of *Tarczynski et al.* in the Octave script *tarczynski_pink_test.m*. The initial filter coefficients are, in gain-pole-zero form:

```
Ux0=3,Vx0=1,Mx0=8,Qx0=10,Rx0=1
x0 = [ 0.0255459662, ...
        -1.5630815475, 0.5547807233, 0.7132875674, ...
        0.8617802369, ...
        0.7788322995, 0.8021238511, 1.5127871497, 1.5922137393, ...
        1.5965134217, 2.6212596629, 0.8496644815, 2.0004450101, ...
        0.4578848116, 0.4739627177, 0.6187484597, 0.7794472969, ...
        0.7985292321, ...
        2.4666020590, 1.2817095605, 0.3724915405, 1.6060455959, ...
        2.6271773316 ]';
```

Figure 8.50 compares the amplitude response of the initial filter to the desired response. Figure 8.51 shows the amplitude response error and group delay of the filter after MMSE and PCCLS optimisation. Figure 8.52 shows the pole-zero plot of the filter.

The PCCLS optimised filter coefficients are, in gain-pole-zero form

```
Ud1=3,Vd1=1,Md1=8,Qd1=10,Rd1=1
d1 = [ 0.0008373550, ...
        -2.7689220720, 0.7584124094, 0.8792520253, ...
        0.961192160, ...
        0.5004489771, 0.9710097792, 3.1179665435, 3.2105286472, ...
        0.0000170108, 0.0297790585, 0.6946295187, 1.8874581075, ...
        0.3346937448, 0.3483906517, 0.5108969144, 0.7585645408, ...
        0.9687500000, ...
        2.4096696932, 1.2408653702, 0.3502475768, 0.0000010091, ...
        0.0248579047 ]';
```

and in transfer function form the numerator and denominator polynomials are, respectively:

```
N1 = [ 0.0008373550, -0.0038537735, 0.0095833256, -0.0185814518, ...
        0.0420624132, 0.1380948761, -0.9211970951, 1.8725192861, ...
        -1.9122153733, 1.0652658514, -0.3090972366, 0.0365849079 ]';
```

and

```

8.2.10 Minimum phase R=2 filter

A minimum phase filter has all the zeros of the transfer function on or within the unit circle in the z -plane $|z| \leq 1$ ^b. The Octave script *iir_sqp_slb_minimum_phase_test.m* designs a minimum phase bandpass filter specified by:

```
n=1000 % Frequency points across the band
tol=0.0005 % Tolerance on relative coefficient update size
ctol=0.0005 % Tolerance on constraints
fap=0.15 % Pass band amplitude response edge
dBap=0.2 % Pass band amplitude peak-to-peak ripple
Wap=1 % Pass band weight
fas=0.2 % Stop band amplitude response edge
dBas=46 % Stop band minimum attenuation
Was=10 % Stop band amplitude weight
U=2 % Number of real zeros
V=1 % Number of real poles
M=8 % Number of complex zeros
Q=4 % Number of complex poles
R=2 % Denominator polynomial decimation factor
```

The initial filter coefficients are, in gain-pole-zero form:

```
x0=[0.002;-1;-1;0.7;ones(4,1);pi*(12:15)'/16;0.7;0.7;2*pi/3;pi/2];
```

The initial filter is optimised with the PCLS algorithm. Figure 8.53 shows the response of the PCLS optimised filter. Figure 8.54 shows the pass-band detail of the response of the PCLS optimised filter. Figure 8.55 shows the pole-zero plot for the PCLS optimised filter. The resulting filter coefficients are, in gain-pole-zero form:

```
Ud1=2,Vd1=1,Md1=8,Qd1=4,Rd1=2
d1 = [ 0.0182425744, ...
        -1.0000000000, -1.0000000000, ...
        0.2633776052, ...
        1.0000000000, 1.0000000000, 1.0000000000, ...
        2.1023174191, 2.3400515153, 1.2857033998, 1.5770643444, ...
        0.5146947869, 0.8607712597, ...
        1.5366166594, 1.9522140914 ]';
```

and in transfer function form the numerator and denominator polynomials are, respectively

```
N1 = [ 0.0182425744, 0.0703239148, 0.1603608998, 0.2697788036, ...
        0.3607727251, 0.3985469619, 0.3607727251, 0.2697788036, ...
        0.1603608998, 0.0703239148, 0.0182425744 ]';
```

and

```
D1 = [ 1.0000000000, 0.0000000000, 0.3422663994, 0.0000000000, ...
        0.8237824252, 0.0000000000, -0.1152814141, 0.0000000000, ...
        0.1584330847, 0.0000000000, -0.0516956380 ]';
```

^bIf the inverse filter is required then the zeros must be within the unit circle, $|z| \leq \rho < 1$.

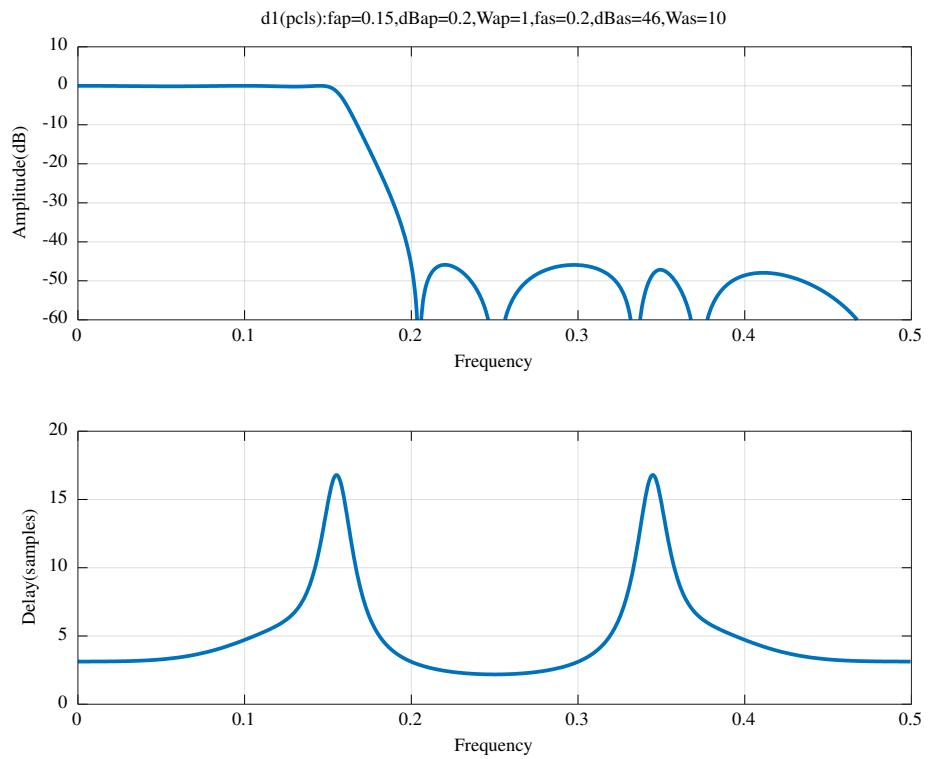

Figure 8.53: Response of the R=2 minimum phase filter after PCLS optimisation

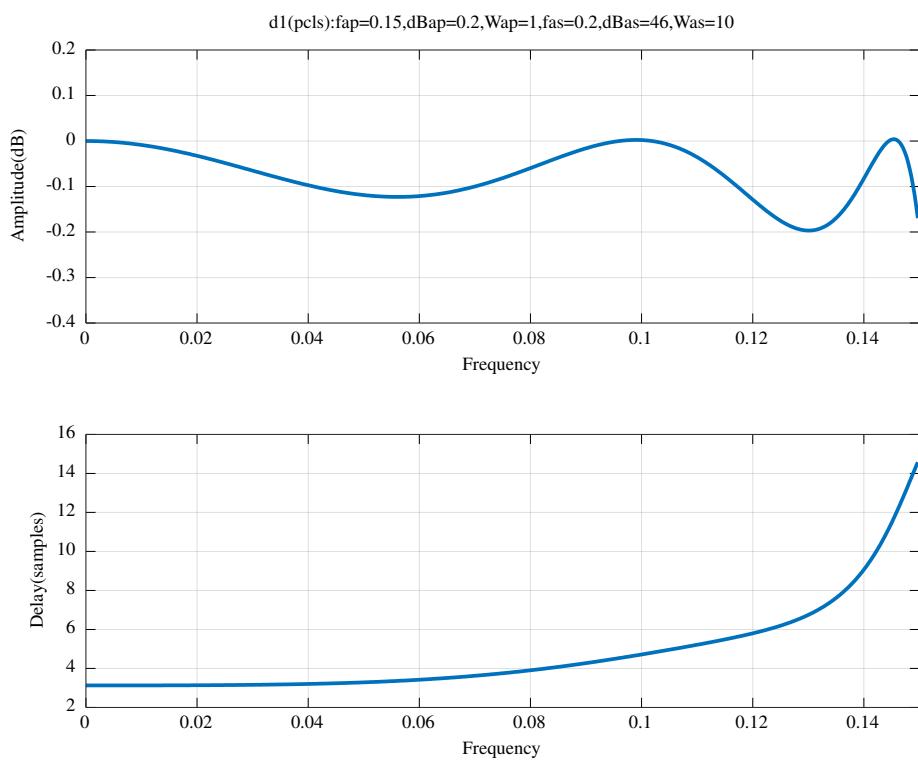

Figure 8.54: Passband response of the R=2 minimum phase filter after PCLS optimisation

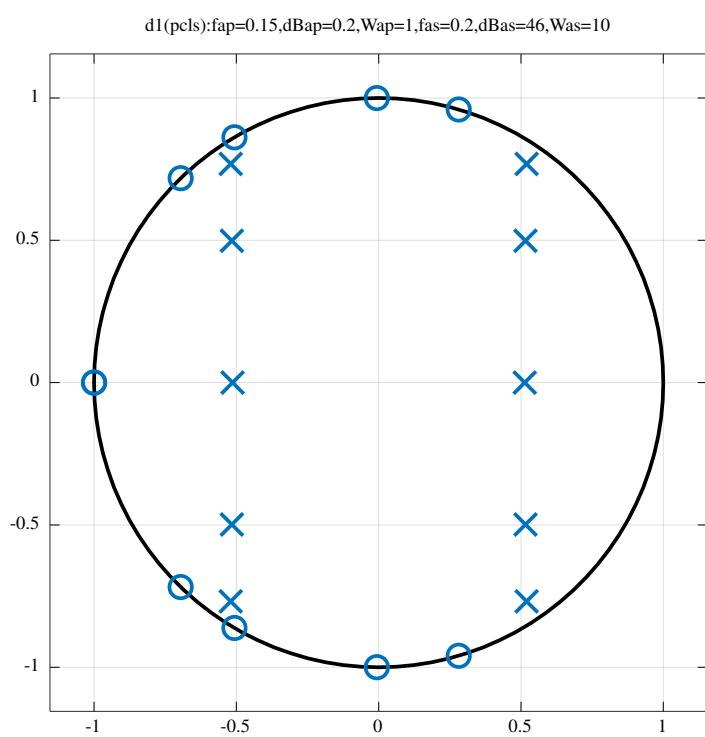

Figure 8.55: Pole-zero plot of the R=2 minimum phase filter after PCLS optimisation

8.2.11 Minimum phase FIR bandpass filter

The Octave script *iir_sqp_slb_fir_bandpass_test.m* designs a minimum phase FIR bandpass filter specified by:

```
U=2,V=0,M=28,Q=0,R=1
fapl=0.1,fapu=0.2,dBap=1,Wap=1
fasl=0.05,fasu=0.25,dBas=36,Wasl=5,Wasu=2
```

The initial filter coefficients are, in gain-pole-zero form:

```
x0=[ 0.005, -0.7, 0.7, 0.7*ones(1,14), pi*[(1:3)/80, (13:23)/24] ]';
```

The zero radiiuses are constrained by $|z| < \frac{31}{32}$. The initial filter is first MMSE optimised and then optimised with the PCLS algorithm. The radiiuses of the zeros of the filter are constrained to $|z| \leq 1$. Figure 8.56 shows the response of the PCLS optimised filter. Figure 8.57 shows the pass-band detail of the response of the PCLS optimised filter. Figure 8.58 shows the pole-zero plot for the PCLS optimised filter. The coefficients of the PCLS optimised minimum phase FIR bandpass filter are, in gain-pole-zero form:

```
Ud1=2,Vd1=0,Md1=28,Qd1=0,Rd1=1
d1 = [ 0.0092548488, ...
        0.9687500000, 0.9687500000, ...
        0.8523023882, 0.8532498033, 0.9298627252, 0.9298871422, ...
        0.9299520918, 0.9302224244, 0.9351184602, 0.9687500000, ...
        0.9687500000, 0.9687500000, 0.9687500000, 0.9687500000, ...
        0.9687500000, 0.9687500000, ...

Alternatively, given an FIR filter of order N , $H(z)$, with the desired magnitude response, $|H(e^{j\omega})| \leq 1$, a more accurate complementary minimum-phase FIR spectral factor of $1 - z^{-N} H(z^{-1}) H(z) = 1 - |H(z)|^2$ can be derived from the real cepstrum (see for example, *Mian and Nainer* [41]) or directly by *Orchard's* Newton-Raphson solution [49]. See Appendix L.1.

Chapter 9

IIR filter design using Second Order Cone Programming

9.1 Second Order Cone Programming

Following *Alizadeh* and *Goldfarb* [35], Second Order Cone Programming (SOCP) is a class of convex optimisation problems in which a linear function is minimised subject to a set of conic constraints

$$\begin{aligned} & \text{minimise} \quad \mathbf{f}^T \mathbf{x} \\ & \text{subject to} \quad \|A_i \mathbf{x} + b_i\| \leq c_i^T \mathbf{x} + h_i \quad i = 1, \dots, N \end{aligned}$$

where $\|\mathbf{u}\| = \sqrt{\mathbf{u}^T \mathbf{u}}$ is the Euclidean norm of the vector \mathbf{u} , $\mathbf{x} \in \mathbb{R}^{p \times 1}$, $\mathbf{f} \in \mathbb{R}^{p \times 1}$, $A_i \in \mathbb{R}^{(p-1) \times p}$, $b_i \in \mathbb{R}^{(p-1) \times 1}$, $c_i \in \mathbb{R}^{p \times 1}$ and $h_i \in \mathbb{R}$. Each constraint is equivalent to:

$$\begin{bmatrix} c_i^T \\ A_i \end{bmatrix} \mathbf{x} + \begin{bmatrix} h_i \\ b_i \end{bmatrix} \in \mathcal{C}_i$$

where \mathcal{C}_i is a cone in \mathbb{R}^p

$$\mathcal{C}_i = \left\{ \begin{bmatrix} t \\ u \end{bmatrix} : u \in \mathbb{R}^{(p-1) \times 1}, t \geq 0, \|u\| \leq t \right\}$$

9.2 Design of IIR filters with SOCP

Equation 2 defined the mini-max optimisation problem for the filter. Rewrite this in terms of an upper bound, ϵ , as

$$\begin{aligned} & \text{minimise} \quad \epsilon \\ & \text{subject to} \quad \|W(\omega_i) [H(\mathbf{x}, \omega_i) - H_d(\omega_i)]\| \leq \epsilon \quad \text{for } \omega_i \in \Omega \\ & \quad H(\mathbf{x}) \text{ is stable} \end{aligned}$$

where \mathbf{x} is the vector of coefficients, ϵ is an auxilliary optimisation variable, $W(\omega)$ is a weighting factor, $H(\mathbf{x}, \omega)$ is the frequency response with coefficients \mathbf{x} and $H_d(\omega)$ is the desired frequency response. $H(\mathbf{x}, \omega)$ and $H_d(\omega)$ usually have complex values in the pass band. The optimisation problem may be formulated so that $H(\mathbf{x}, \omega)$ and $H_d(\omega)$ are complex scalars or vectors of complex values. In the latter case the norm is assumed to be summed over a range of frequencies.

If $\nabla_{\mathbf{x}} H(\mathbf{x}_k, \omega)$ is known and the step-size, $\|\mathbf{x} - \mathbf{x}_k\|$, is small, then a useful *first-order* approximation to $H(\mathbf{x}, \omega)$ is:

$$H(\mathbf{x}, \omega) \approx H(\mathbf{x}_k, \omega) + \nabla_{\mathbf{x}} H(\mathbf{x}_k, \omega)^T (\mathbf{x} - \mathbf{x}_k)$$

so that

$$\begin{aligned} W(\omega) |H(\mathbf{x}, \omega) - H_d(\omega)| & \approx W(\omega) \left| \nabla_{\mathbf{x}} H(\mathbf{x}_k, \omega)^T (\mathbf{x} - \mathbf{x}_k) + H(\mathbf{x}_k, \omega) - H_d(\omega) \right| \\ & = W(\omega) \left| \nabla_{\mathbf{x}} H(\mathbf{x}_k, \omega)^T (\mathbf{x} - \mathbf{x}_k) + \mathbf{e}_k \right| \end{aligned}$$

where $e_k = H(\mathbf{x}_k, \omega) - H_d(\omega)$.

Similarly, a *second-order* approximation to $H(\mathbf{x}, \omega)$ is:

$$H(\mathbf{x}, \omega) \approx H(\mathbf{x}_k, \omega) + \nabla_x H(\mathbf{x}_k, \omega)^T (\mathbf{x} - \mathbf{x}_k) + \frac{1}{2} (\mathbf{x} - \mathbf{x}_k)^T \nabla_{xx}^2 H(\mathbf{x}_k, \omega) (\mathbf{x} - \mathbf{x}_k)$$

Unfortunately the IIR filter Hessian matrix, $\nabla_{xx}^2 H(\mathbf{x}_k, \omega)$, is unlikely to be positive definite.

Lu and Hinamoto [160] add linear constraints on the maximum filter response in the transition band, Ω_t :

$$\|\nabla_x H(\mathbf{x}_k, \omega_t)^T (\mathbf{x} - \mathbf{x}_k) + H(\mathbf{x}_k, \omega_t)\| \leq \gamma \quad \text{for } \omega_t \in \Omega_t$$

Similar linear constraints can be added to control the peaks of the response in the pass and stop bands.

The linearised SOCP optimisation problem is

$$\begin{aligned} & \text{minimise} \quad \epsilon \\ & \text{subject to} \quad \|W(\omega_i) [\nabla_x H(\mathbf{x}_k, \omega_i)^T (\mathbf{x} - \mathbf{x}_k) + e_k]\| \leq \epsilon \quad \text{for } \omega_i \in \Omega \\ & \quad \|\nabla_x H(\mathbf{x}_k, \omega_t)^T (\mathbf{x} - \mathbf{x}_k) + H(\mathbf{x}_k, \omega_t)\| \leq \gamma \quad \text{for } \omega_t \in \Omega_t \\ & \quad \|\mathbf{x} - \mathbf{x}_k\| \leq \beta \\ & \quad H(\mathbf{x}) \text{ is stable} \end{aligned}$$

There are three sets of second-order cone constraints (for the desired response, the transition band response and for the coefficient step size) and one set of linear constraints (for filter stability). The optimisation is repeated until the step size, $(\mathbf{x} - \mathbf{x}_k)$, is satisfactory or the iteration limit is exceeded. Typically, ϵ minimises the weighted sum of, for example, the amplitude and delay errors, \mathcal{E}_A and \mathcal{E}_T . Separately minimising the amplitude and delay errors implies the minimisation of two auxilliary variables ϵ_A and ϵ_T .

The complex frequency response can be written in terms of amplitude and phase as

$$\begin{aligned} H(\mathbf{x}_k, \omega_i) &= H_a(\mathbf{x}_k, \omega_i) e^{iH_p(\mathbf{x}_k, \omega_i)} \\ &= H_a(\mathbf{x}_k, \omega_i) [\cos H_p(\mathbf{x}_k, \omega_i) + i \sin H_p(\mathbf{x}_k, \omega_i)] \end{aligned}$$

so that, at each ω_i , the gradient of the complex frequency response is

$$\begin{aligned} \nabla_x H(\mathbf{x}_k, \omega_i) &= [\cos H_p(\mathbf{x}_k, \omega_i) \nabla_x H_a(\mathbf{x}_k, \omega_i) - H_a(\mathbf{x}_k, \omega_i) \sin H_p(\mathbf{x}_k, \omega_i) \nabla_x H_p(\mathbf{x}_k, \omega_i)] \dots \\ &\quad + i [\sin H_p(\mathbf{x}_k, \omega_i) \nabla_x H_a(\mathbf{x}_k, \omega_i) + H_a(\mathbf{x}_k, \omega_i) \cos H_p(\mathbf{x}_k, \omega_i) \nabla_x H_p(\mathbf{x}_k, \omega_i)] \end{aligned}$$

The squared magnitude of the response is used if there is no design constraint on the phase of the filter response (for example in the stop band). In this case

$$\begin{aligned} |H(\mathbf{x}_k, \omega_i)|^2 &= H(\mathbf{x}_k, \omega_i) H(\mathbf{x}_k, \omega_i)^\dagger \\ \nabla_x |H(\mathbf{x}_k, \omega_i)|^2 &= (\nabla_x H(\mathbf{x}_k, \omega_i)) H(\mathbf{x}_k, \omega_i)^\dagger + H(\mathbf{x}_k, \omega_i) (\nabla_x H(\mathbf{x}_k, \omega_i))^\dagger \\ &= 2\Re \nabla_x H(\mathbf{x}_k, \omega_i) \Re H(\mathbf{x}_k, \omega_i) + 2\Im \nabla_x H(\mathbf{x}_k, \omega_i) \Im H(\mathbf{x}_k, \omega_i) \end{aligned}$$

where \dagger represents the element-wise complex conjugate. The squared-magnitude response can be used in linear constraints on the upper and lower peaks of the pass-band and stop-band magnitude responses

$$\begin{aligned} |H(\mathbf{x}_k, \omega_i)|^2 + (\mathbf{x} - \mathbf{x}_k)^T \nabla_x |H(\mathbf{x}_k, \omega_i)|^2 &\geq H_{d,l}^2(\omega_i) \\ |H(\mathbf{x}_k, \omega_i)|^2 + (\mathbf{x} - \mathbf{x}_k)^T \nabla_x |H(\mathbf{x}_k, \omega_i)|^2 &\leq H_{d,u}^2(\omega_i) \end{aligned}$$

where $H_{d,l}^2(\omega)$ and $H_{d,u}^2(\omega)$ are the lower and upper constraints on the squared-magnitude response. A similar linear constraint on the phase response uses

$$\begin{aligned} \phi_H(\mathbf{x}_k, \omega_i) &= \arctan \frac{\Im H(\mathbf{x}_k, \omega_i)}{\Re H(\mathbf{x}_k, \omega_i)} \\ \nabla_x \phi_H(\mathbf{x}_k, \omega_i) &= \frac{\Re H(\mathbf{x}_k, \omega_i) \Im \nabla_x H(\mathbf{x}_k, \omega_i) - \Im H(\mathbf{x}_k, \omega_i) \Re \nabla_x H(\mathbf{x}_k, \omega_i)}{|H(\mathbf{x}_k, \omega_i)|^2} \end{aligned}$$

9.3 Using the *SeDuMi* SOCP solver

In the following I use the *SeDuMi* (*Self-Dual-Minimisation*) SOCP solver originally written by *Jos Sturm* [149]. The *Colophon* shows construction of a *patch* file that makes *SeDuMi v1.3* compatible with Octave.

Lu [166, Section III] provides an example of expressing an optimisation problem in the form accepted by SeDuMi. In Lu's notation the problem is

$$\text{minimise} \quad \mathbf{b}^T \mathbf{x} \quad (9.1a)$$

$$\text{subject to} \quad \| \mathbf{A}_i^T \mathbf{x} + \mathbf{c}_i \| \leq \mathbf{b}_i^T \mathbf{x} + d_i \quad \text{for } i = 1, \dots, q \quad (9.1b)$$

$$\mathbf{D}^T \mathbf{x} + \mathbf{f} \geq \mathbf{0} \quad (9.1c)$$

where $\mathbf{x} \in \mathbb{R}^{m \times 1}$, $\mathbf{D} \in \mathbb{R}^{m \times p}$, $\mathbf{f} \in \mathbb{R}^{p \times 1}$, $\mathbf{b} \in \mathbb{R}^{m \times 1}$, $\mathbf{A}_i \in \mathbb{R}^{m \times (n_i - 1)}$ ^a, $\mathbf{b}_i \in \mathbb{R}^{m \times 1}$, $\mathbf{c}_i \in \mathbb{R}^{(n_i - 1) \times 1}$ and $d_i \in \mathbb{R}$ for $1 \leq i \leq q$. The problem is cast into SeDuMi format by defining

$$\begin{aligned} \mathbf{A}_t &= \begin{bmatrix} -\mathbf{D} & \mathbf{A}_t^{(1)} \dots \mathbf{A}_t^{(q)} \end{bmatrix} \\ \mathbf{A}_t^{(i)} &= -[\mathbf{b}_i \quad \mathbf{A}_i] \\ \mathbf{b}_i &= -\mathbf{b} = [-1 \quad 0 \quad \dots \quad 0]^T \\ \mathbf{c}_t &= [\mathbf{f}; \quad \mathbf{c}_t^{(1)}; \quad \dots \quad \mathbf{c}_t^{(q)}] \\ \mathbf{c}_t^{(i)} &= [d_i; \quad \mathbf{c}_i] \end{aligned} \quad (9.2)$$

The Octave commands to solve the SOCP problem with SeDuMi are

```
K.p = p;
K.q = q;
[xs,ys,info] = sedumi(At,bt,ct,K);
info
x = ys;
```

where p is the number of linear constraints in Equation 9.1c and q is a vector giving the dimensions of the q sets of conic constraints in Equation 9.1b, $\mathbf{q} = [n_1 \quad n_2 \quad \dots \quad n_q]$.

^a $n_i - 1$ to allow for d_i in the column vector $\mathbf{c}_t^{(i)}$

9.4 An example of SOCP design of an IIR filter expressed in *gain-zero-pole* format with *SeDuMi*

The Octave script *deczky3_socp_test.m* implements the design of Deczky's Example 3, used previously in Section 8.2.3, with MMSE optimisation of the weighted response error by the *SeDuMi* SOCP solver. As in Part 8, the coefficients of this example filter are expressed in *gain-zero-pole* form and the amplitude and group-delay are calculated with the *iirA* and *iirT* functions. Similarly, filter stability is ensured by linear constraints on the upper and lower values of the coefficients.

As for the filter design in Section 8.2.3, the *deczky3_socp_test.m* script has two phases. First, starting with the "IPSZ-1" coefficients the sum of the coefficient step-size and MMSE error is minimised in the the Octave function *iir_socp_mmse.m*. Linesearch along the minimal direction is not required. The minimisation variables are

$$\mathbf{x} = \begin{bmatrix} \epsilon \\ \beta \\ \delta \end{bmatrix}$$

where ϵ is the MMSE error, δ is the step direction from coefficient vector \mathbf{x}_k , and β is the constraint on the coefficient step-size, $\|\delta\| \leq \beta$.

In a similar fashion to the MMSE error used in Part 8, the MMSE frequency response constraint can be expressed as a weighted sum of pass-band amplitude response, A , stop-band amplitude response, S , and group-delay response, T . In this example I do not attempt to control the transition band amplitude response. In *SeDuMi* format

$$\begin{aligned} \mathbf{A}_i^T &= \begin{bmatrix} \mathbf{0} & W_a(\omega_s) \nabla_x A(\mathbf{x}_k, \omega_a) \\ \mathbf{0} & W_t(\omega_t) \nabla_x T(\mathbf{x}_k, \omega_t) \\ \mathbf{0} & W_s(\omega_s) \nabla_x S(\mathbf{x}_k, \omega_s) \end{bmatrix} \\ \mathbf{b}_i^T &= [1 \ 0 \ \mathbf{0}] \\ \mathbf{c}_i &= \begin{bmatrix} W_a(\omega_a) [A(\mathbf{x}_k, \omega_a) - A_d(\omega_a)] \\ W_t(\omega_t) [T(\mathbf{x}_k, \omega_t) - T_d(\omega_t)] \\ W_s(\omega_s) [S(\mathbf{x}_k, \omega_s) - S_d(\omega_s)] \end{bmatrix} \\ d_i &= 0 \end{aligned}$$

where $\omega_a \in \Omega_a$, $\omega_t \in \Omega_t$ and $\omega_s \in \Omega_s$ are the pass band amplitude, and pass band group delay and stop band amplitude response grid frequencies and $A_d(\omega_a)$, $T_d(\omega_t)$ and $S_d(\omega_s)$ are the desired pass band amplitude, pass band delay and stop band amplitude responses, respectively.

The gain-zero-pole coefficients have upper and lower constraints, \mathbf{x}_u and \mathbf{x}_l respectively, ensuring stability with

$$\begin{aligned} -(\mathbf{x} - \mathbf{x}_k) - (\mathbf{x}_k - \mathbf{x}_u) &\geq 0 \\ (\mathbf{x} - \mathbf{x}_k) - (\mathbf{x}_l - \mathbf{x}_k) &\geq 0 \end{aligned}$$

The stability constraint is a linear constraint on the coefficients

$$\begin{aligned} \mathbf{D}^T &= \begin{bmatrix} \mathbf{0} & -\mathbf{I} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} \\ \mathbf{f} &= \begin{bmatrix} -(\mathbf{x}_k - \mathbf{x}_u) \\ -(\mathbf{x}_l - \mathbf{x}_k) \end{bmatrix} \end{aligned}$$

During the second, PCLS, phase, the Octave function, *iir_slb.m* minimises the sum of the coefficient step-size and the MMSE error subject to linear constraints on the pass-band amplitude response, stop-band amplitude response and group-delay response. For example, the pass-band amplitude response upper and lower constraints are

$$\begin{aligned} A_{du}(\mathbf{x}_k, \omega_{au}) - \left[A(\mathbf{x}_k, \omega_{au}) + \nabla_x A(\mathbf{x}_k, \omega_{au})^T \delta \right] &\geq 0 \\ -A_{dl}(\mathbf{x}_k, \omega_{al}) + \left[A(\mathbf{x}_k, \omega_{al}) + \nabla_x A(\mathbf{x}_k, \omega_{al})^T \delta \right] &\geq 0 \end{aligned}$$

where $\omega_{au} \in \Omega_{au}$ and $\omega_{al} \in \Omega_{al}$ are the upper and lower pass-band amplitude response constraint frequencies. These constraints are added to the *SeDuMi* problem as linear constraints. The constraint frequencies are determined by the PCLS peak-exchange algorithm of Selesnick *et al.* shown in Algorithm 8.1.

The *deczky3_socp_test.m* script has somewhat tighter constraints on the pass-band group-delay ripple than the SQP design of *deczky3_sqp_test.m* shown in Section 8.2.3. The filter specification is

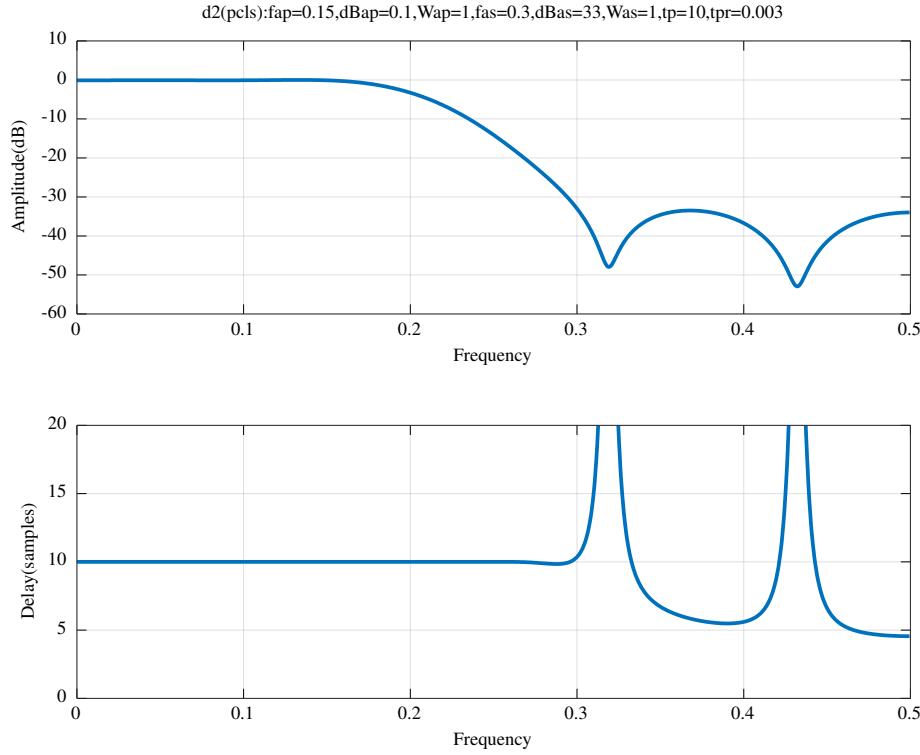

Figure 9.1: Deczky Example 3 PCLS : Response after SOCP optimisation

```

n=500 % Frequency points across the band

For comparison, the *deczky3a_socp_test.m* script has looser constraints on the pass-band group-delay ripple and increases the required stop-band attenuation:

```
n=500 % Frequency points across the band
tol=2e-05 % Tolerance on relative coefficient update size
ctol=2e-05 % Tolerance on constraints
fap=0.15 % Pass band amplitude response edge
dBap=0.2 % Pass band amplitude peak-to-peak ripple
Wap=1 % Pass band weight
ftp=0.25 % Pass band group delay response edge
tp=10 % Nominal filter group delay
tpr=0.5 % Pass band group delay peak-to-peak ripple
Wtp=0.1 % Pass band group delay weight
fas=0.3 % Stop band amplitude response edge
dBas=50 % Stop band minimum attenuation
Was=2 % Stop band amplitude weight
U=0 % Number of real zeros
V=0 % Number of real poles
M=10 % Number of complex zeros
Q=6 % Number of complex poles
R=1 % Denominator polynomial decimation factor
```

The result of the PCLS SOCP pass in *deczky3a_socp_test.m* is shown in Figure 9.4 with pass-band details shown in Figure 9.5 and pole-zero plot shown in Figure 9.6. The estimate of the SOCP PCLS optimised filter vector is, in the gain, zeros and poles form of Equation 8.2:

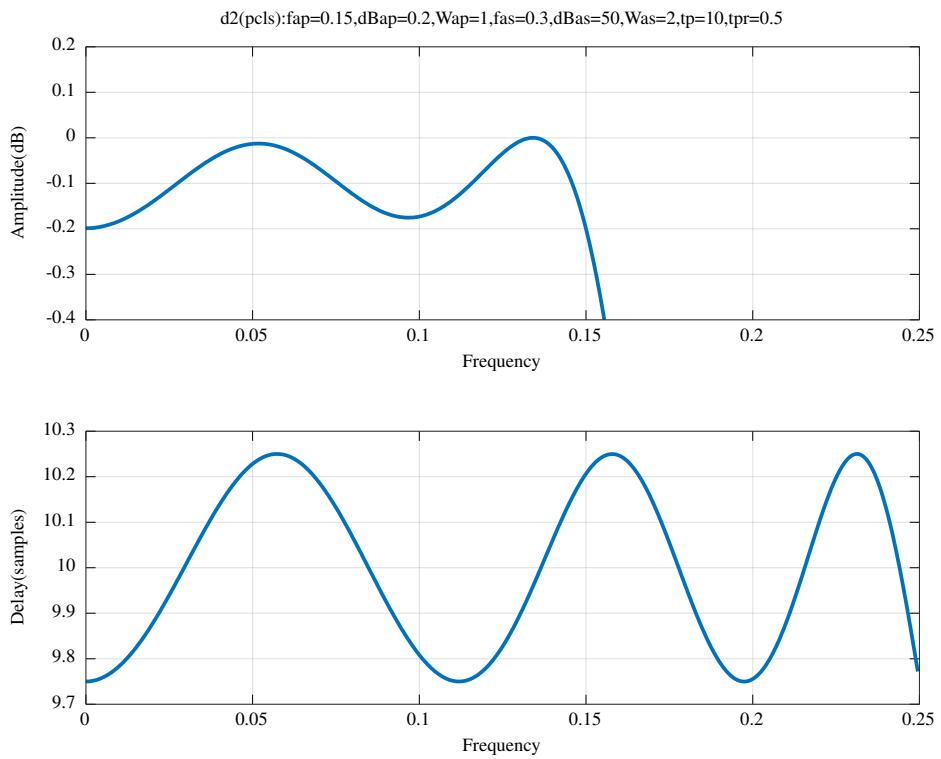

Figure 9.5: Deczky Example 3 PCLS : Passband response after SOCP optimisation, alternative specification

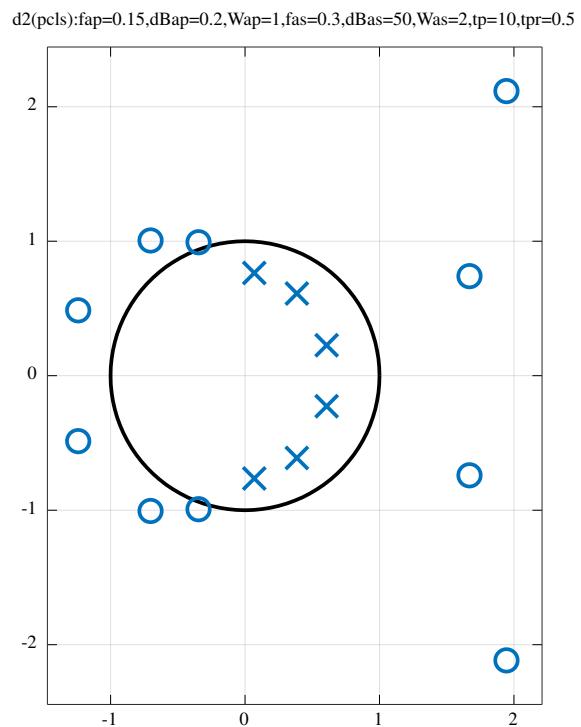

Figure 9.6: Deczky Example 3 PCLS : Pole-zero plot after SOCP optimisation, alternative specification

```

Ud2=0,Vd2=0,Md2=10,Qd2=6,Rd2=1
d2 = [ 0.0007124751, ...

In Section 8.1.1, I expressed the filter design problem as a *sequential quadratic programming*, or SQP, problem:

$$\text{minimise } q(\mathbf{x}) = \frac{1}{2} \mathbf{x}^T \mathbf{Q} \mathbf{x} + \mathbf{a}^T \mathbf{x} + \beta$$

where \mathbf{Q} is positive definite and symmetric and linear constraints are neglected for clarity. This SQP optimisation problem can be converted to an SOCP problem by rearranging $q(\mathbf{x})$:

$$q(\mathbf{x}) = \frac{1}{2} \|\mathbf{Q}^{\frac{1}{2}} \mathbf{x} + \mathbf{Q}^{-\frac{1}{2}} \mathbf{a}\|^2 + \beta - \frac{1}{2} \mathbf{a}^T \mathbf{Q}^{-1} \mathbf{a}$$

See Alizadeh and Goldfarb [35, Section 2.1] or Antoniou and Lu [2, Section 14.7.2].

The Octave script *deczky3_socp_bfgs_test.m* implements the design of Deczky's Example 3, with the SeDuMi SOCP solver, as in Section 9.4, but with MMSE optimisation of the weighted response error, $\mathcal{E}(\mathbf{x})$, represented as $\|\mathbf{Q}^{\frac{1}{2}} \mathbf{x} + \mathbf{Q}^{-\frac{1}{2}} \nabla_x \mathcal{E}(\mathbf{x})\|$, where \mathbf{Q} is initialised with the diagonal of $\nabla_{xx}^2 \mathcal{E}(\mathbf{x})$ and updated with the BFGS Hessian matrix update algorithm shown in Appendix I.7.1.

The filter specification is

```

U=0 % Number of real zeros
V=0 % Number of real poles
M=10 % Number of complex zeros
Q=6 % Number of complex poles
R=1 % Denominator polynomial decimation factor
n=1000 % Frequency points across the band
tol=1e-06 % Tolerance on relative coefficient update size
ctol=1e-06 % Tolerance on constraints
fap=0.15 % Pass band amplitude response edge
dBap=0.1 % Pass band amplitude peak-to-peak ripple
Wap=1 % Pass band weight
ftp=0.25 % Pass band group delay response edge
tp=10 % Nominal filter group delay
tpr=0.08 % Pass band group delay peak-to-peak ripple
Wtp=0.2 % Pass band group delay weight
fas=0.3 % Stop band amplitude response edge
dBas=40 % Stop band minimum attenuation
Was=10 % Stop band amplitude weight

```

The result of the PCLS SOCP pass in *deczky3_socp_bfgs_test.m* is shown in Figure 9.7 with pass-band details shown in Figure 9.8 and pole-zero plot shown in Figure 9.9.

The estimate of the SOCP PCLS optimised filter vector is, in the gain, zeros and poles form of Equation 8.2:

```

Ud2=0,Vd2=0,Md2=10,Qd2=6,Rd2=1
d2 = [ 0.0028603104, ...
        1.1153479872, 1.1326276735, 1.1339470220, 1.8249200653, ...
        2.1304862990, ...
        2.7293066380, 2.0494174526, 1.8375913334, 0.7412308707, ...

9.5 Comparison of FIR and IIR low-pass filters having approximately flat pass-band group delay with symmetric FIR filters

The Octave script *compare_fir_iir_socp_slb_lowpass_test.m* compares the performance of FIR and IIR implementations of a low-pass filter having 31 coefficients and a pass-band group delay of approximately 10 samples designed by the *SeDuMi* solver with symmetric FIR low-pass filters having 21 and 31 coefficients designed by the Octave *remez* function. The low-pass filter pass-band and stop-band edges are 0.15 and 0.2, respectively, and the allowed pass-band ripple is 3dB. The IIR filter specification is:

```

U=3 % Number of real zeros
V=1 % Number of real poles
M=12 % Number of complex zeros
Q=14 % Number of complex poles
R=1 % Denominator polynomial decimation factor
n=1000 % Frequency points across the band
tol=0.0001 % Tolerance on relative coefficient update size
ctol=1e-06 % Tolerance on constraints
rho=0.992188 % Constraint on pole radius
fap=0.15 % Pass band amplitude response edge
dBap=3 % Pass band amplitude peak-to-peak ripple
Wap=1 % Pass band amplitude weight
Wat=0.001 % Transition band amplitude weight
ftp=0.155 % Pass band group-delay response edge
td=10 % Pass band group-delay
tdr=0.2 % Pass band amplitude peak-to-peak ripple
Wtp=0.01 % Pass band group-delay weight
Wtt=0.001 % Transition band group-delay weight
fas=0.2 % Stop band amplitude response edge
dBas=45 % Stop band minimum attenuation
Was=20 % Stop band amplitude weight

```

The *gain-zero-pole* FIR filter specification is:

```

U=2 % Number of real zeros
V=0 % Number of real poles
M=28 % Number of complex zeros
Q=0 % Number of complex poles
R=1 % Denominator polynomial decimation factor
n=1000 % Frequency points across the band
tol=0.0001 % Tolerance on relative coefficient update size
ctol=1e-06 % Tolerance on constraints
fap=0.15 % Pass band amplitude response edge
dBap=3 % Pass band amplitude peak-to-peak ripple
Wap=1 % Pass band amplitude weight
ftp=0.15 % Pass band group-delay response edge
td=10 % Pass band group-delay
tdr=0.6 % Pass band amplitude peak-to-peak ripple
Wtp=0.01 % Pass band group-delay weight
fas=0.2 % Stop band amplitude response edge
dBas=40 % Stop band minimum attenuation
Was=50 % Stop band amplitude weight

```

The symmetric FIR filters were designed with:

```
d10=remez(20,[0 0.15 0.2 0.5]*2,[1 1 0 0],[1 7]);
```

and

```
d15=remez(30,[0 0.15 0.2 0.5]*2,[1 1 0 0],[1 50]);
```

Figure 9.10 compares the amplitude responses of the four filters and Figure 9.11 compares the delay responses (the flat delay of 15 samples of the order 30 symmetric FIR filter is not shown).

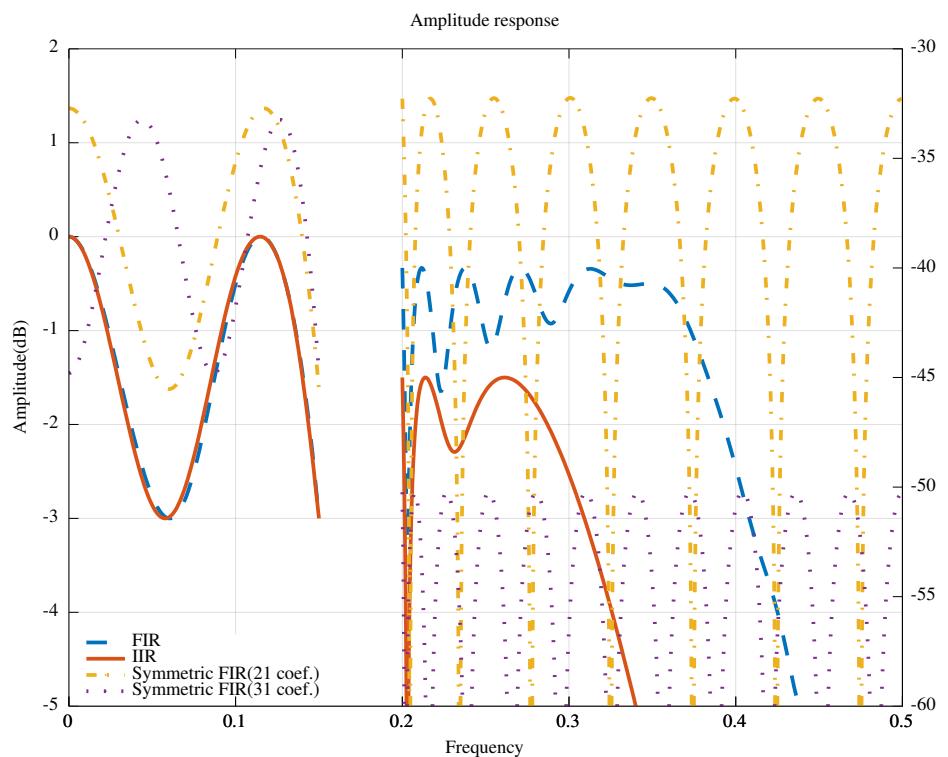

Figure 9.10: Comparison of FIR and IIR low-pass filters : Amplitude responses

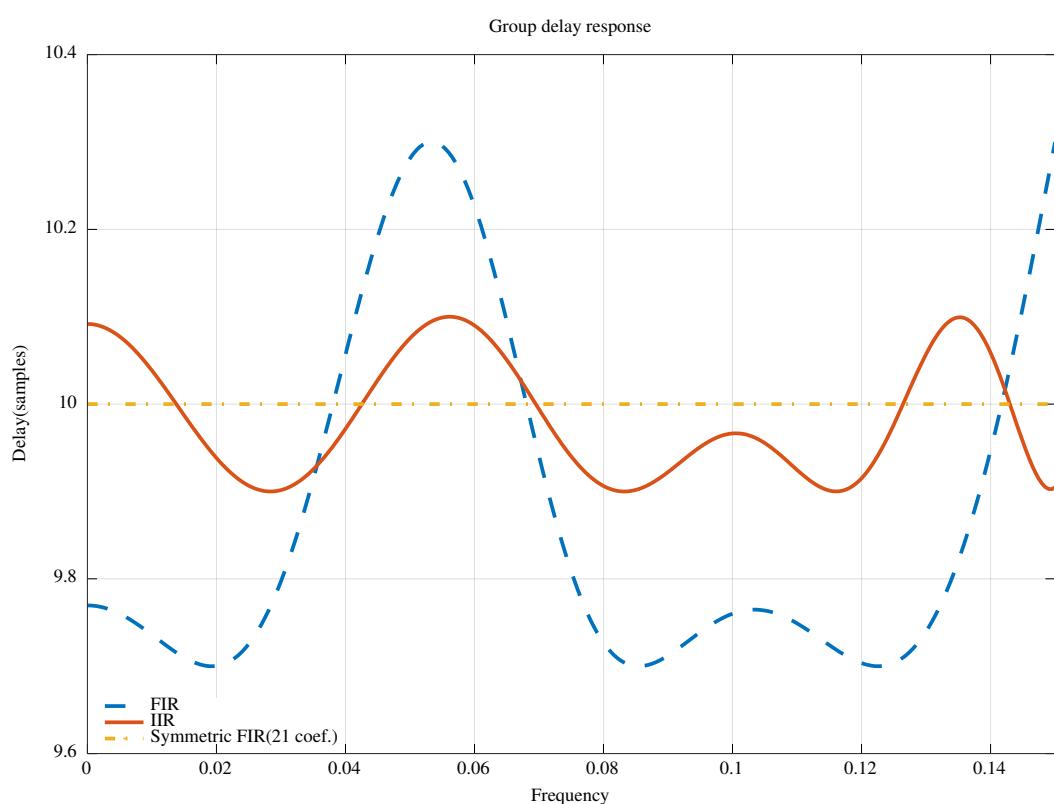

Figure 9.11: Comparison of FIR and IIR low-pass filters : Group delay responses

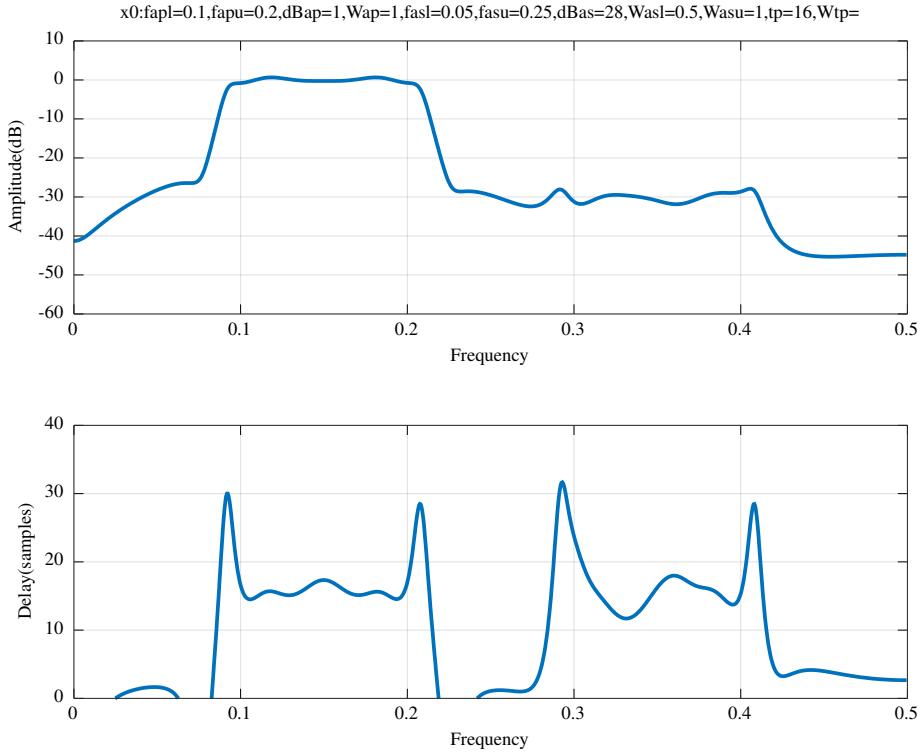

Figure 9.12: IIR band-pass R=2 decimation filter : response of the initial filter calculated with the WISE method of Tarczynski *et al.*

9.6 SOCP MMSE design of a bandpass R=2 filter expressed in gain-zero-pole format with SeDuMi

The Octave script *iir_socp_slb_bandpass_test.m* uses the *SeDuMi* SOCP solver to design an $R = 2$ bandpass filter similar to that designed with the SQP solver in Section 8.2.6. After some experimentation, the filter specification is:

```

n=500 % Frequency points across the band
tol=0.0001 % Tolerance on relative coefficient update size
ctol=0.0001 % Tolerance on constraints
fasl=0.05 % Stop band amplitude response lower edge
fapl=0.1 % Pass band amplitude response lower edge
fapu=0.2 % Pass band amplitude response upper edge
fasu=0.25 % Stop band amplitude response upper edge
dBap=1 % Pass band amplitude peak-to-peak ripple
dBas=28 % Stop band amplitude peak-to-peak ripple
Wasl=0.5 % Lower stop band weight
Wap=1 % Pass band weight
Wasu=1 % Upper stop band weight
ftpl=0.09 % Pass band group delay response lower edge
ftpup=0.21 % Pass band group delay response upper edge
tp=16 % Nominal filter group delay
tpr=0.04 % Pass band group delay peak-to-peak ripple
Wtp=1 % Pass band group delay weight
U=2 % Number of real zeros
V=0 % Number of real poles
M=18 % Number of complex zeros
Q=10 % Number of complex poles
R=2 % Denominator polynomial decimation factor

```

The *SeDuMi* solver seems to require the initial filter to be a closer approximation than that required by the SQP solver. In this case, the initial filter is calculated by the Octave function *tarczynski_bandpass_test.m*. The response of the initial filter is shown in Figure 9.12. After PCLS SOCP optimisation, the response of the resulting filter is shown in Figure 9.13 with pass-band detail shown in Figure 9.14. The corresponding pole-zero plot is shown in Figure 9.15. The estimate of the optimised filter vector is, in the gain, zeros and poles form of Equation 8.2:

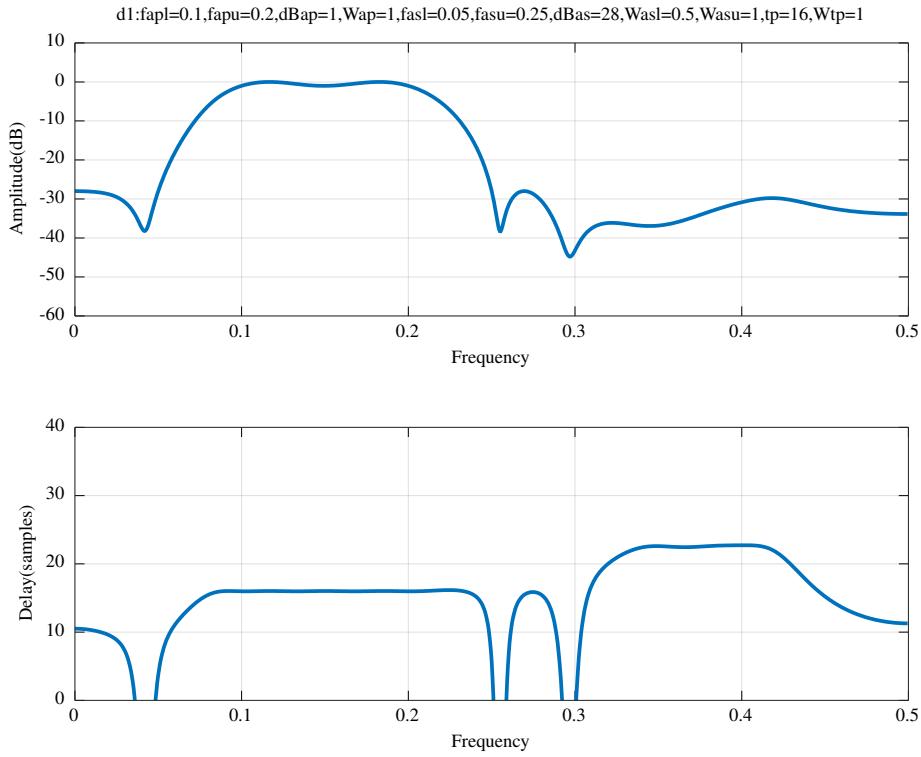

Figure 9.13: IIR band-pass R=2 decimation filter with delay tp=16 samples : response of the filter after PCLS SOCP optimisation

```

Chapter 10

IIR filter design with a pre-defined structure

In this chapter I describe the design of IIR filters with a predefined structure.

10.1 Design of an IIR filter composed of second-order sections

In this section I consider the MMSE design of an IIR filter consisting of a cascade of second-order sections (with one first-order section if the transfer function polynomial order is odd). The stability of the IIR filter is ensured by a linear constraint on the coefficients of the denominator second-order sections. (See *Lu and Hinamoto* [159]).

10.1.1 Linear constraints on the stability of second-order filter sections

A digital filter is stable if its poles (the zeros of the denominator polynomial of the filter transfer function) lie within the unit circle in the z -plane, $|z| < 1$. Suppose the filter denominator polynomial is decomposed into one first order section, $z + d_0$, and second order sections of the form $z^2 + d_1 z + d_2$. The pole location of the first order section is constrained by

$$\begin{aligned} d_0 &> -1 \\ -d_0 &> -1 \end{aligned}$$

If the roots of the second order polynomial lie within the unit circle $|z| < 1$ then

$$\left| \frac{-d_1 \pm \sqrt{d_1^2 - 4d_2}}{2} \right| < 1$$

If the roots are complex then $d_1^2 \leq 4d_2$ and

$$\frac{d_1^2 + 4d_2 - d_1^2}{4} < 1$$

so $-d_2 > -1$.

If the roots are real then $d_1^2 \geq 4d_2$ and

$$\begin{aligned} \left| \frac{-d_1 \pm \sqrt{d_1^2 - 4d_2}}{2} \right| &< 1 \\ \pm \sqrt{d_1^2 - 4d_2} &< 2 \pm d_1 \end{aligned}$$

Squaring both sides

$$\pm d_1 + d_2 > -1$$

If a margin $0 < \tau \ll 1$ is applied to the first and second order sections then:

$$d_0 > -1 + \tau$$

$$\begin{aligned} -d_0 &> -1 + \tau \\ d_1 + d_2 &> -1 + \tau \\ -d_1 + d_2 &> -1 + \tau \\ -d_2 &> -1 + \tau \end{aligned}$$

Suppose the denominator polynomial has odd order $2L + 1$. Define the coefficients of the corresponding first and second order sections and the stability constraint matrixes as

$$\begin{aligned} \mathbf{d} &= \begin{bmatrix} d_0 \\ \mathbf{d}_1 \\ \vdots \\ \mathbf{d}_L \end{bmatrix} & \text{where } \mathbf{d}_i = \begin{bmatrix} d_{i1} \\ d_{i2} \end{bmatrix} \\ \mathbf{C} &= \begin{bmatrix} c_1 & & & \mathbf{0} \\ & c_2 & & \\ & & \ddots & \\ \mathbf{0} & & & c_2 \end{bmatrix} & \text{where } c_1 = \begin{bmatrix} 1 \\ -1 \end{bmatrix} \text{ and } c_2 = \begin{bmatrix} 1 & 1 \\ -1 & 1 \\ 0 & 1 \end{bmatrix} \\ \mathbf{e} &= \begin{bmatrix} e_1 \\ e_2 \\ \vdots \\ e_2 \end{bmatrix} & \text{where } e_1 = \begin{bmatrix} 1 \\ 1 \end{bmatrix} \text{ and } e_2 = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} \end{aligned}$$

The stability constraint on the filter denominator polynomial is

$$\mathbf{C}\mathbf{d} + (1 - \tau)\mathbf{e} \geq \mathbf{0}$$

Suppose the coefficient vector, \mathbf{d} , is perturbed by $\boldsymbol{\delta}$. Then the stability constraint becomes

$$\mathbf{C}\boldsymbol{\delta} + \mathbf{h} \geq \mathbf{0}$$

where $\mathbf{h} = \mathbf{C}\mathbf{d} + (1 - \tau)\mathbf{e}$.

10.1.2 Linear constraints on limit-cycle oscillations in second-order filter sections

Section 3.2 states that second-order section limit-cycle oscillations can be suppressed by adding the constraint:

$$|d_1| + |d_2| \leq 1$$

so that, in addition to the stability constraints shown in the previous section:

$$\begin{aligned} d_1 - d_2 &> -1 + \tau \\ -d_1 - d_2 &> -1 + \tau \end{aligned}$$

and

$$\begin{aligned} e_2 &= \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} \\ c_2 &= \begin{bmatrix} 1 & 1 \\ -1 & 1 \\ 1 & -1 \\ -1 & -1 \\ 0 & 1 \end{bmatrix} \end{aligned}$$

10.1.3 Design of an IIR filter composed of second order sections with *SeDuMi*

For the IIR filter transfer function

$$H(z) = \frac{a(z)}{d(z)}$$

where

$$a(z) = \sum_{i=0}^n a_i z^{-i}$$

and $d(z)$ is a polynomial of order r expressed as a product of second order sections (with one first order section if r is odd)

$$d(z) = \begin{cases} (1 + d_0 z^{-1}) \prod_{i=1}^{\frac{r-1}{2}} (1 + d_{i1} z^{-1} + d_{i2} z^{-2}), & \text{if } r \text{ odd} \\ \prod_{i=1}^{\frac{r}{2}} (1 + d_{i1} z^{-1} + d_{i2} z^{-2}), & \text{if } r \text{ even} \end{cases}$$

Define the two filter coefficient vectors as

$$\mathbf{a} = [a_0 \ a_1 \ \dots \ a_n]^T$$

and

$$\begin{aligned} \mathbf{d} &= \begin{bmatrix} d_0 \\ d_1 \\ \vdots \\ d_L \end{bmatrix} \\ \mathbf{d}_i &= \begin{bmatrix} d_{i1} \\ d_{i2} \end{bmatrix}, \quad \text{for } 1 \leq i \leq L \\ L &= \begin{cases} \frac{r-1}{2}, & \text{if } r \text{ odd} \\ \frac{r}{2}, & \text{if } r \text{ even} \end{cases} \end{aligned}$$

The frequency response of the filter is

$$H(\omega) = \frac{\mathbf{a}^T \mathbf{v}(\omega)}{d(\omega)}$$

where

$$\begin{aligned} \mathbf{v}(\omega) &= \mathbf{c}(\omega) - i\mathbf{s}(\omega) \\ \mathbf{c}(\omega) &= [1 \ \dots \ \cos n\omega]^T \\ \mathbf{s}(\omega) &= [0 \ \dots \ -\sin n\omega]^T \\ v_1(\omega) &= \cos \omega - i \sin \omega \\ \mathbf{v}_2(\omega) &= \begin{bmatrix} \cos \omega \\ \cos 2\omega \end{bmatrix} - i \begin{bmatrix} \sin \omega \\ \sin 2\omega \end{bmatrix} \end{aligned}$$

and

$$d(\omega) = \begin{cases} [1 + d_0 v_1(\omega)] \prod_{i=1}^L [1 + \mathbf{d}_i^T \mathbf{v}_2(\omega)], & \text{if } r \text{ odd} \\ \prod_{i=1}^L [1 + \mathbf{d}_i^T \mathbf{v}_2(\omega)], & \text{if } r \text{ even} \end{cases}$$

The gradients of $H(\omega)$ with respect to the coefficients are

$$\begin{aligned} \frac{\partial H(\omega)}{\partial \mathbf{a}} &= \frac{\mathbf{v}(\omega)}{d(\omega)} \\ \frac{\partial H(\omega)}{\partial d_0} &= -H(\omega) \frac{v_1(\omega)}{1 + d_0 v_1(\omega)} \\ \frac{\partial H(\omega)}{\partial \mathbf{d}_i} &= -H(\omega) \frac{\mathbf{v}_2(\omega)}{1 + \mathbf{d}_i^T \mathbf{v}_2(\omega)} \quad \text{for } 1 \leq i \leq L \end{aligned}$$

In this case we optimise the complex frequency response (gain and delay). For each of the response frequencies the format for solution by *SeDuMi* is

$$\begin{aligned}\mathbf{A}_i^T &= W(\omega_i) \begin{bmatrix} 0 & \Re \nabla_x H(\omega_i)^T \\ 0 & \Im \nabla_x H(\omega_i)^T \end{bmatrix} \\ \mathbf{b}_i^T &= [1 \ 0] \\ \mathbf{c}_i &= W(\omega_i) \begin{bmatrix} 0 & \Re[H(\omega_i) - H_d(\omega_i)] \\ 0 & \Im[H(\omega_i) - H_d(\omega_i)] \end{bmatrix} \\ d_i &= 0\end{aligned}$$

where x represents the vector of coefficients and the desired low pass filter frequency response is

$$H_d(\omega) = \begin{cases} e^{-i\omega t_d} & \text{if } 0 \leq \omega \leq \omega_{pass} \\ 10^{-\frac{dBstop}{20}} & \text{if } \omega_{pass} < \omega \end{cases}$$

The Octave script *lowpass2ndOrderCascade_socp_test.m* calls the Octave function *lowpass2ndOrderCascade_socp* to implement MMSE SOCP design of a low pass filter similar to that of Deczky's Example 3:

```
tol=1e-06 % Tolerance on coefficient update vector
mn=10 % Numerator order (mn+1 coefficients)
mr=6 % Denominator order (mr coefficients)
tau=0.1 % Second order section stability parameter
n=400 % Number of frequency points
td=10 % Pass band group delay
fpass= 0.15 % Pass band edge
Wpass=1 % Pass band weight
fstop= 0.3 % Stop band edge
Wstop=100 % Stop band weight
dBstop=80 % Stop band attenuation
```

The filter coefficients are initialised with the “IPZS-1” set. The script does not enforce the limit-cycle constraints. After SOCP MMSE optimisation, the numerator and denominator polynomials are respectively:

```
a = [ -0.0021092647, 0.0004069327, 0.0076883393, 0.0051931734, ...

The overall frequency response of the MMSE SOCP design is shown in Figure 10.1 with pass-band details shown in Figure 10.2 and pole-zero plot shown in Figure 10.3.

Additionally, the Octave function *lowpass2ndOrderCascade_socp.m* optimises only the squared-magnitude response and ignores the group delay response. The resulting overall magnitude and delay responses are shown in Figure 10.4, the passband responses are shown in Figure 10.5 and the pole-zero plot is shown in Figure 10.6.

10.1.4 Some notes on the design of an IIR filter composed of second order sections with *SeDuMi*

Some notes on SOCP optimisation of a filter composed of a cascade of second order sections with *SeDuMi*:

- when running SeDuMi under Octave with the default options, SeDuMi sometimes fails due to numerical problems. This indicates that the optimisation problem is not feasible with the current constraints.
- a better response is obtained by using a single constraint on the summed response error (MMSE) rather than a large number of separate frequency response constraints.
- the response is sensitive to the stop band weight.
- the passband response is improved if the desired stop band amplitude response is set to a small non-zero value.
- I did not find a useful filter when attempting to optimise the complex response in the pass band simultaneously with the squared-magnitude response in the stop band.
- a second order section may have complex conjugate roots or two real roots. In the gain-zero-pole format the total number of real and complex conjugate roots is specified in advance.

10.2 Design of an IIR filter as the sum of two all-pass filters

In this section I consider the design of a low-pass IIR filter that is the sum of two parallel all-pass filters, $A(z)$ and $B(z)$

$$H(z) = \frac{A(z) + B(z)}{2} \quad (10.1)$$

Vaidyanathan *et al.* [116] demonstrate that the “classical” odd-order lowpass digital filter approximations can be implemented as the sum of two allpass filters. The resulting filters have low sensitivity to coefficient quantisation.

10.2.1 Design of an IIR filter as the sum of two all-pass filters each composed of second-order sections

Following Lu and Hinamoto [159], the transfer functions of the $A(z)$ and $B(z)$ filters are expressed as the product of second-order sections. As shown in Section 10.1.1, the second-order filter sections permit a simple linear stability constraint on the coefficients of each section.

Assume that the order of $H(z)$ is odd and that that

$$\begin{aligned} a(z) &= (1 + a_0 z^{-1}) \prod_{k=1}^{\frac{m-1}{2}} 1 + a_{k1} z^{-1} + a_{k2} z^{-2} \\ A(z) &= z^{-m} \frac{a(z^{-1})}{a(z)} \end{aligned}$$

and

$$\begin{aligned} b(z) &= \prod_{k=1}^{\frac{n}{2}} 1 + b_{k1} z^{-1} + b_{k2} z^{-2} \\ B(z) &= z^{-n} \frac{b(z^{-1})}{b(z)} \end{aligned}$$

Here the coefficients a_{k1} etc. are real, m is odd, n is even and the order of H is $p = n + m$. In the following, references to $A(z)$ apply to $B(z)$ as appropriate. The frequency response of $A(z)$ is:

$$\begin{aligned} A(\omega) &= e^{-im\omega} \frac{a(-\omega)}{a(\omega)} \\ a(\omega) &= (1 + a_0 v_1) \prod_{k=1}^{\frac{m-1}{2}} 1 + \mathbf{v}_2 \mathbf{a}_k \end{aligned}$$

where $\mathbf{a}_k = \begin{bmatrix} a_{k1} \\ a_{k2} \end{bmatrix}$, $v_1 = \cos \omega - i \sin \omega$, $\mathbf{v}_2 = [\cos \omega \cos 2\omega] - i [\sin \omega \sin 2\omega]$ and $A(\omega)$ is understood to mean $A(e^{i\omega})$.

The gradients of $A(z)$ with respect to its coefficients a_0 , a_{k1} and a_{k2} are

$$\begin{aligned} \frac{\partial A(z)}{\partial a_0} &= A(z) \frac{z - z^{-1}}{1 + a_0^2 + a_0(z + z^{-1})} \\ \frac{\partial A(z)}{\partial a_{k1}} &= A(z) \frac{(z - z^{-1})(1 - a_{k2})}{1 + a_{k1}^2 + a_{k2}^2 + a_{k1}(1 + a_{k2})(z + z^{-1}) + a_{k2}(z^2 + z^{-2})} \\ \frac{\partial A(z)}{\partial a_{k2}} &= A(z) \frac{(z - z^{-1})(a_{k1} + z + z^{-1})}{1 + a_{k1}^2 + a_{k2}^2 + a_{k1}(1 + a_{k2})(z + z^{-1}) + a_{k2}(z^2 + z^{-2})} \end{aligned}$$

The Octave function `allpass2ndOrderCascade.m` returns the complex frequency response and gradient of an allpass filter consisting of a cascade of 2nd-order allpass sections (with a single additional first order section if the filter order is odd).

Similarly to Section 9.4, the parallel allpass filter design problem can be expressed in SOCP form as

$$\text{minimise } \epsilon, \beta$$

subject to

$$\|W(\omega_i) \begin{bmatrix} \Re \nabla H(\mathbf{a}_k, \mathbf{b}_k, \omega_i)^T \\ \Im \nabla H(\mathbf{a}_k, \mathbf{b}_k, \omega_i)^T \end{bmatrix} \boldsymbol{\delta} + W(\omega_i) \begin{bmatrix} \Re H(\mathbf{a}_k, \mathbf{b}_k, \omega_i) - \Re H_d(\omega_i) \\ \Im H(\mathbf{a}_k, \mathbf{b}_k, \omega_i) - \Im H_d(\omega_i) \end{bmatrix}\| \leq \epsilon$$

$$\|\boldsymbol{\delta}\| \leq \beta$$

$$C\boldsymbol{\delta} + \mathbf{h} \geq \mathbf{0}$$

where

$$\boldsymbol{\delta} = \begin{bmatrix} \mathbf{a} - \mathbf{a}_k \\ \mathbf{b} - \mathbf{b}_k \end{bmatrix}$$

$$H(\mathbf{a}_k, \mathbf{b}_k, \omega_i) = 0.5 [A(\mathbf{a}_k, \omega_i) + B(\mathbf{b}_k, \omega_i)]$$

$$\nabla H(\mathbf{a}_k, \mathbf{b}_k, \omega_i) = 0.5 [\nabla_a A(\mathbf{a}_k, \omega_i) + \nabla_b B(\mathbf{b}_k, \omega_i)]$$

A quadratic constraint on the squared-magnitude response at the stop-band frequencies is

$$\|\nabla H^2(\mathbf{a}_k, \mathbf{b}_k, \omega_i)^T \boldsymbol{\delta} + H^2(\mathbf{a}_k, \mathbf{b}_k, \omega_i)\| \leq |H_d(\omega_i)|^2$$

where

$$H^2(\mathbf{a}_k, \mathbf{b}_k, \omega_i) = \|H(\mathbf{a}_k, \mathbf{b}_k, \omega_i)\|^2$$

$$= 0.25 [\Re A(\mathbf{a}_k, \omega_i) + \Re B(\mathbf{b}_k, \omega_i)]^2 + 0.25 [\Im A(\mathbf{a}_k, \omega_i) + \Im B(\mathbf{b}_k, \omega_i)]^2$$

$$\nabla H^2(\mathbf{a}_k, \mathbf{b}_k, \omega_i) = 0.5 [\Re A(\mathbf{a}_k, \omega_i) + \Re B(\mathbf{b}_k, \omega_i)] [\Re \nabla_a A(\mathbf{a}_k, \omega_i) + \Re \nabla_b B(\mathbf{b}_k, \omega_i)] + \dots$$

$$0.5 [\Im A(\mathbf{a}_k, \omega_i) + \Im B(\mathbf{b}_k, \omega_i)] [\Im \nabla_a A(\mathbf{a}_k, \omega_i) + \Im \nabla_b B(\mathbf{b}_k, \omega_i)]$$

Design of an IIR filter as the sum of two 2nd order cascade all-pass filters with MMSE optimisation of the complex response

The Octave script *allpass2ndOrderCascade_socp_test.m* calls the Octave function *allpass2ndOrderCascade_socp* to design a low-pass filter composed of two parallel all-pass filters with MMSE optimisation of the complex response of the filter. The filter specification is similar to Deczky's Example 3. The desired low pass filter frequency response is:

$$H_d(\omega) = \begin{cases} e^{-i\omega t_d} & \text{if } 0 \leq \omega \leq \omega_{pass} \\ 0 & \text{if } \omega_{pass} < \omega \end{cases}$$

and the filter specification is

```
tol=1e-06 % Tolerance on coefficient update vector
ma=11 % Order of filter A
mb=12 % Order of filter B
tau=0.001 % Second order section stability parameter
n=1000 % Number of frequency points
resp=complex % Flat passband group delay or squared-magnitude
fp= 0.15 % Pass band edge
td=11.5 % Pass band nominal group delay
Wp=2 % Pass band weight
fs= 0.2 % Stop band edge
Ws=20 % Stop band weight
```

The initial allpass filters were designed by the Octave script *tarczynski_allpass2ndOrderCascade_test.m* with *flat_delay = true*. The initial response is shown in Figure 10.7.

After optimisation with the *SeDuMi* SOCP solver the response is shown in Figure 10.8 with passband detail shown in Figure 10.9 and pole-zero plot shown in Figure 10.10. The second-order section coefficients are

```
a1 = [ -0.5030245427, 0.5356269479, 0.4548414034, 0.3489059354, ...

```

Design of an IIR filter as the sum of two 2nd order cascade all-pass filters with MMSE optimisation of the squared-magnitude response

The Octave script *allpass2ndOrderCascade_socp_sqmag_test.m* calls the Octave function *allpass2ndOrderCascade_socp* to design a low-pass filter composed of two parallel all-pass filters with MMSE optimisation of the squared-magnitude response of the filter. The filter specification is

```
tol=1e-08 % Tolerance on coefficient update vector
ma=5 % Order of filter A
mb=6 % Order of filter B
tau=0.001 % Second order section stability parameter
n=1000 % Number of frequency points
resp=sqmag % Flat passband group delay or squared-magnitude
fp= 0.15 % Pass band edge
Wp=1 % Pass band weight
fs= 0.17 % Stop band edge
Ws=1000 % Stop band weight
```

The initial allpass filters were designed by the Octave script *tarczynski_allpass2ndOrderCascade_test.m* with *flat_delay = false*. The initial response is shown in Figure 10.11.

After optimisation with the *SeDuMi* SOCP solver the response is shown in Figure 10.12 and the pole-zero plot is shown in Figure 10.13. The second-order section coefficients are

```
a1 = [ -0.6213602510, -1.1447331694, 0.8971339377, -1.2186074024, ...
        0.6264446514 ]';
```

and

```
b1 = [ -1.1417688731, 0.9698861081, -1.1753899632, 0.7861255542, ...
        -1.2421568387, 0.4598952357 ]';
```

The corresponding allpass filter denominator polynomials are

```
Da1 = [ 1.0000000000, -2.9847008227, 4.3870447938, -3.6238425210, ...
        1.6868942467, -0.3492074167 ]';
```

and

```
Db1 = [ 1.0000000000, -3.5593156749, 6.4362052665, -6.9514641734, ...
        4.7182030766, -1.8841531366, 0.3506481592 ]';
```

For comparison, Figures 10.14 and 10.15 show the response and pole-zero plot of an elliptic filter designed with a similar specification:

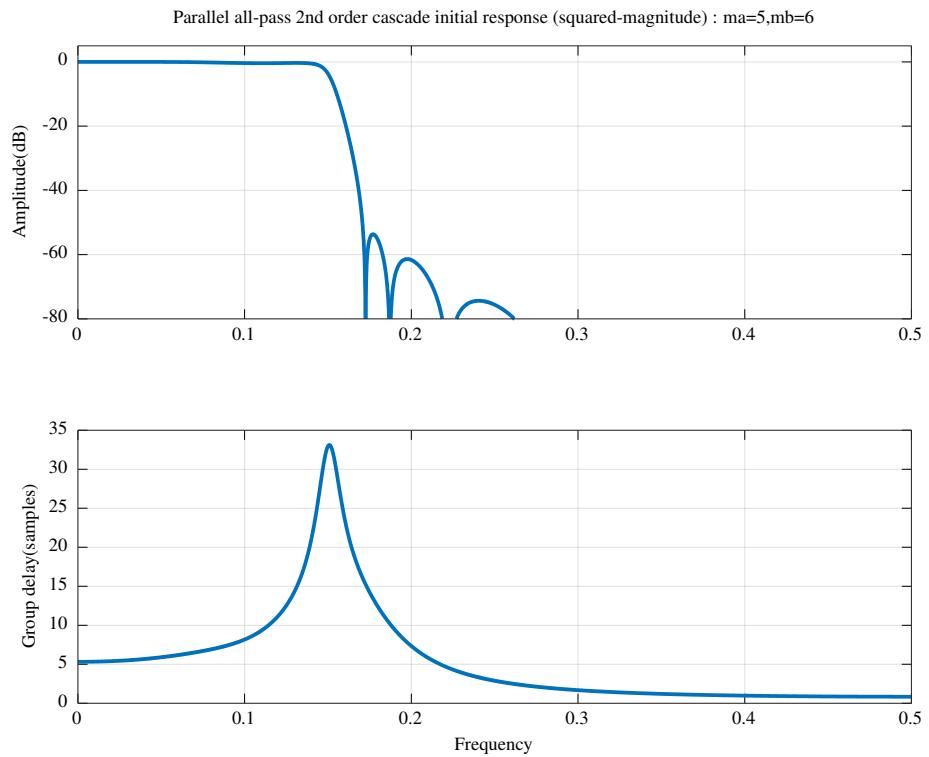

Figure 10.11: Parallel 2nd order allpass cascade filters (squared magnitude) : Initial response found with the WISE barrier function

10.2.2 Design of an IIR filter as the sum of an all-pass filter composed of second-order sections and a delay

The Octave script *allpass2ndOrderCascadeDelay_socp_test.m* designs a lowpass filter consisting of an allpass filter in parallel with a pure delay. The allpass filter is composed of a cascade of second-order sections, as described in Section 10.2.1. The filter specification is:

```
n=500 % Number of frequency points
tol=1e-06 % Tolerance on coefficient update vector
tau=0.05 % Second order section stability parameter
ma=11 % Order of allpass filter
D=10 % Parallel delay in samples
td=10 % Nominal filter group delay in samples
fap= 0.15 % Pass band edge
Wap=1 % Pass band weight
fas= 0.2 % Stop band edge
Was=10 % Stop band weight (complex response)
Was_sqm=200 % Stop band weight (squared-magnitude)
```

This script produces two designs. The first attempts to optimise the filter for flat group-delay in the passband and the second ignores the phase response and optimises the weighted squared-magnitude response. The relative weights in each case are shown in the specification. The initial allpass filter was designed by the Octave script *tarczynski_allpass_phase_shift_test.m* to have a phase shift of 0 radians in the pass band and π radians in the stop band. The phase response of the initial allpass filter is shown in Figure 10.16. The phase has been adjusted by ωD , where D is the number of samples in the pure delay branch.

The allpass filter polynomial found for the optimised delay case is:

```
Da1 = [ 1.0000000000, -0.4940632912, 0.3737009599, 0.1807528325, ...
0.0198375902, -0.0547182791, -0.0506744694, -0.0144919076, ...
0.0113201529, 0.0138227843, 0.0045376389, -0.0041454492 ]';
```

with the overall filter response shown in Figure 10.17.

The allpass filter polynomial found for the optimised squared-magnitude case is:

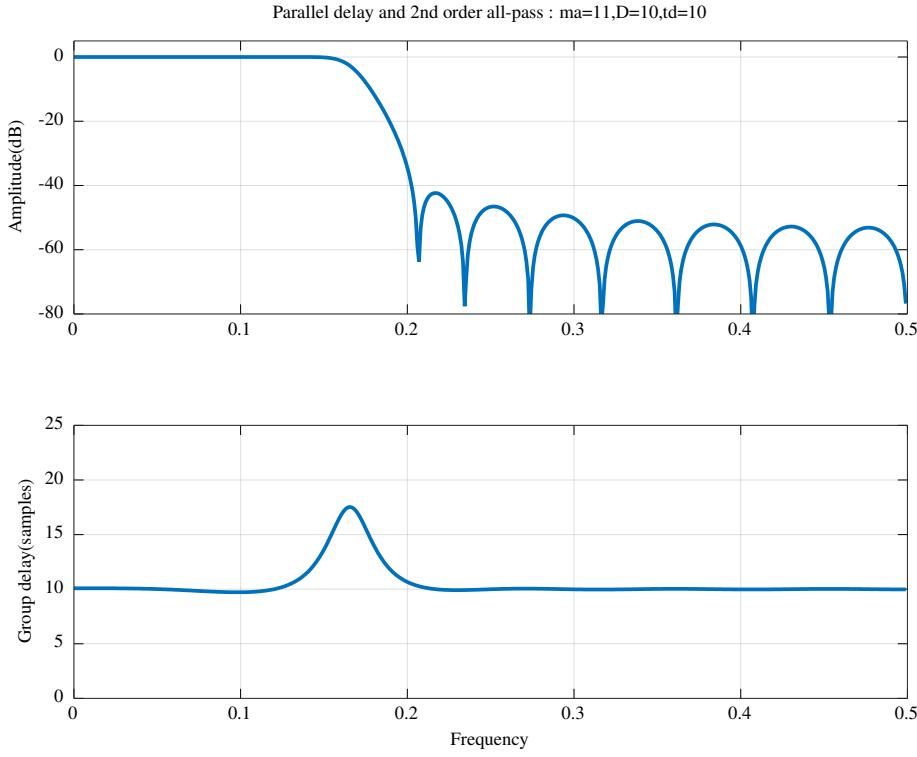

Figure 10.17: Parallel all-pass 2nd order cascade filter and delay : Overall response optimised for flat pass band group delay

```
Dalsqm = [ 1.0000000000, -0.5292155430, 0.3637414504, 0.1968593379, ...
0.0368342339, -0.0661347518, -0.0989859314, -0.0823773869, ...
-0.0478345377, -0.0194755183, -0.0051849904, -0.0007373687 ]';
```

with the overall filter response shown in Figure 10.18. At the filter band edges the change in phase of the allpass branch produces a corresponding transient in the group delay response.

10.2.3 Design of an IIR filter as the sum of two all-pass filters each represented in pole-zero form

Rewriting Equation 10.1 in terms of the phase responses of the component all-pass filters gives

$$H(z) = \frac{e^{i\phi_1(z)} + e^{i\phi_2(z)}}{2}$$

where $\phi_1(z) = \phi_{A_1}(z)$ and $\phi_2(z) = \phi_{A_2}(z)$. The squared magnitude response and phase of the frequency response, $H(\omega)$, are:

$$\begin{aligned} |H(\omega)|^2 &= \frac{1 + \cos(\phi_1(\omega) - \phi_2(\omega))}{2} \\ \phi_H(\omega) &= \frac{\phi_1(\omega) + \phi_2(\omega)}{2} \end{aligned}$$

The group delay response is

$$T(\omega) = -\frac{1}{2} \left[\frac{\partial \phi_1(\omega)}{\partial \omega} + \frac{\partial \phi_2(\omega)}{\partial \omega} \right]$$

The partial derivatives of the squared-magnitude, phase and group delay with respect to the real and complex conjugate pole radiiuses of filters A_1 and A_2 (for convenience all represented here by r), are:

$$\begin{aligned} \frac{\partial |H(\omega)|^2}{\partial r} &= -\frac{1}{2} \sin(\phi_1(\omega) - \phi_2(\omega)) \left\{ \frac{\partial \phi_1(\omega)}{\partial r} - \frac{\partial \phi_2(\omega)}{\partial r} \right\} \\ \frac{\partial \phi_H(\omega)}{\partial r} &= \frac{1}{2} \left\{ \frac{\partial \phi_1(\omega)}{\partial r} + \frac{\partial \phi_2(\omega)}{\partial r} \right\} \end{aligned}$$

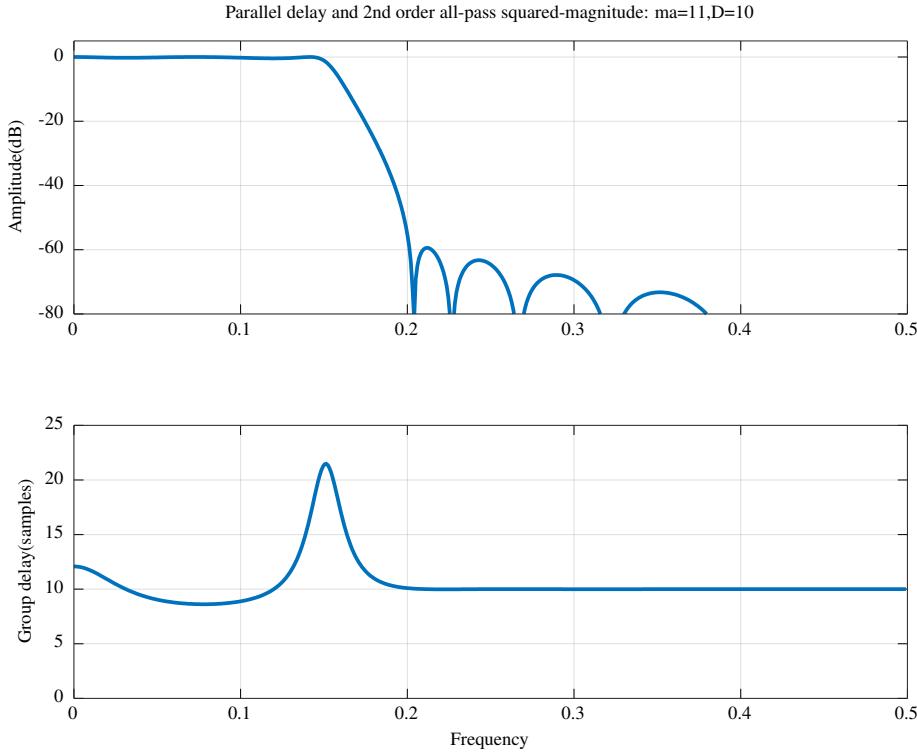

Figure 10.18: Parallel all-pass 2nd order cascade filter and delay : Overall response optimised for squared-magnitude

$$\frac{\partial T(\omega)}{\partial r} = -\frac{1}{2} \left\{ \frac{\partial^2 \phi_1(\omega)}{\partial r \partial \omega} + \frac{\partial^2 \phi_2(\omega)}{\partial r \partial \omega} \right\}$$

The partial derivatives with respect to the filter pole angles, θ , are similar. Appendix G.1 derives the phase response of an all-pass filter and the partial derivatives of the phase response with respect to the real and complex conjugate pole locations. The Octave function *allpassP* calculates the phase response and partial derivatives of the phase response of an all-pass IIR filter. The Octave function *allpassT* calculates the group delay response and partial derivatives of the group delay response of an all-pass IIR filter. The Octave function *parallel_allpassAsq* calls *allpassP* to calculate the squared-magnitude and partial derivatives of the squared magnitude response of the parallel combination of two allpass IIR filters and is exercised by the test script *parallel_allpassAsq_test.m*. Similarly, the Octave function *parallel_allpassP* calls *allpassP* to calculate the phase and partial derivatives of the phase response of the parallel combination of two all-pass IIR filters and is exercised by the test script *parallel_allpassP_test.m*. Finally, the Octave function *parallel_allpassT* calls *allpassT* to calculate the group delay and partial derivatives of the group delay response of the parallel combination of two all-pass IIR filters and is exercised by the test script *parallel_allpassT_test.m*.

Design of an IIR filter as the sum of two all-pass filters each represented in pole-zero form with no constraints on the group delay

The Octave script *parallel_allpass_socp_slb_test.m* calls the Octave function *parallel_allpass_slb* to perform the PCLS design of a low-pass filter composed of two parallel all-pass filters in terms of the all-pass filter pole locations. This script does not constrain the group delay of the filter. The PCLS algorithm of Selesnick, Lang and Burrus was reviewed in Section 8.1.2. At each iteration of the PCLS optimisation the Octave function *parallel_allpass_socp_mmse* optimises the filter response subject to the current constraints. The filter specification is

```

polyphase=0 % Use polyphase combination
tol=0.0001 % Tolerance on coefficient update vector
ctol=1e-10 % Tolerance on constraints
n=2000 % Frequency points across the band
ma=5 % Allpass model filter A denominator order
K=10 % Scale factor
Va=1 % Allpass model filter A no. of real poles
Qa=4 % Allpass model filter A no. of complex poles
Ra=1 % Allpass model filter A decimation
mb=6 % Allpass model filter B denominator order

```

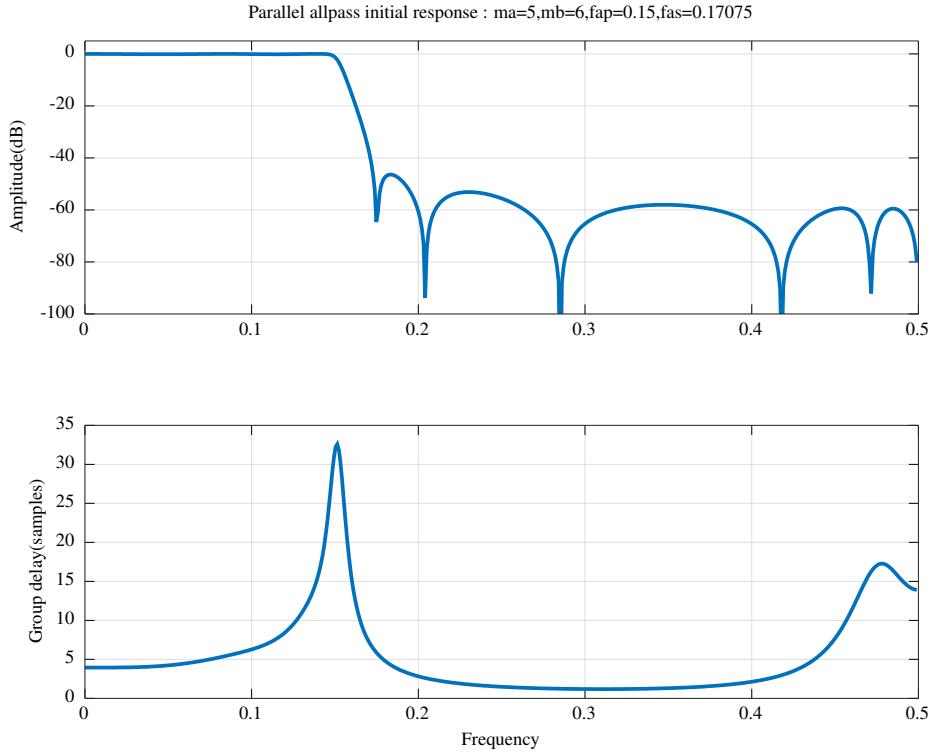

Figure 10.19: Parallel all-pass filters : Initial response found with the WISE barrier function

```
Vb=0 % Allpass model filter B no. of real poles
Qb=6 % Allpass model filter B no. of complex poles
Rb=1 % Allpass model filter B decimation
fap=0.15 % Pass band amplitude response edge
dBap=0.020000 % Pass band amplitude response ripple
Wap=1 % Pass band amplitude response weight
fas=0.17075 % Stop band amplitude response edge
dBas=84.020000 % Stop band amplitude response ripple
Was_mmse=500000 % Stop band amplitude response weight (MMSE)
Was_pcls=1e-06 % Stop band amplitude response weight (PCLS)
rho=0.999000 % Constraint on allpass pole radius
```

Compare this filter with the elliptic filter shown in Figure 10.14. The response of that filter is slightly wider than the specification. The response of the filter shown here is intended to match that slight extra width in the transition band.

The initial parallel all-pass filters were designed by the Octave script *tarczynski_parallel_allpass_test.m* (with *flat_delay = false*), using the *WISE* method described in Section 8.1.5. The response of the initial filter is shown in Figure 10.19. The pole-zero plot of the initial filter is shown in Figure 10.20.

The script first runs an MMSE pass on the initial filter. The squared-amplitude error weighting function increases linearly near the band edges. The resulting MMSE optimised response is shown in Figure 10.21.

The PCLS pass does not attempt to minimise the stop-band response minimum mean-squared squared-amplitude error. Instead the stop-band squared-amplitude response is controlled by the PCLS constraints. In this case, the desired stop-band attenuation is more than 80dB and the filter response is scaled to make the stop-band squared-amplitude greater than the machine precision. The default SeDuMi *pars.eps* is of the same order as the desired stop-band attenuation and must be reduced to avoid the PCLS algorithm cycling between solutions. The denominator polynomials of the two all-pass filters are:

```
Da1 = [ 1.0000000000, -2.9591405190, 4.3510159397, -3.6072165779, ...

```

The overall numerator polynomial is symmetric to within the precision of the calculations and has pairs of reciprocal zeros that do not lie on the unit circle. This should be compared with the pole-zero plot resulting when the delay is not constrained, Figure 10.23, and the pole-zero plot for the elliptic filter example, Figure 10.15.

Design of an IIR filter as the difference of two all-pass filters each represented in pole-zero form with constraints on the group delay

If the filter of Equation 10.1 is rewritten as the difference of two all-pass filters:

$$H(z) = \frac{e^{i\phi_1(z)} - e^{i\phi_2(z)}}{2}$$

then the squared magnitude response and phase of the frequency response, $H(\omega)$, are, with simple trigonometry

$$\begin{aligned} |H(\omega)|^2 &= \frac{1 - \cos(\phi_1(\omega) - \phi_2(\omega))}{2} \\ \phi_H(\omega) &= \frac{\phi_1(\omega) + \phi_2(\omega)}{2} + \frac{\pi}{2} \end{aligned}$$

Clearly, the group delay response is unchanged:

$$T(\omega) = -\frac{1}{2} \left[\frac{\partial \phi_1(\omega)}{\partial \omega} + \frac{\partial \phi_2(\omega)}{\partial \omega} \right]$$

The Octave script *parallel_allpass_socp_slb_bandpass_test.m* uses the SeDuMi SOCP solver to design a band-pass filter consisting of the difference of two all-pass filters. The script calls the Octave function *parallel_allpass_slb* to perform the PCLS design of the filter in terms of the all-pass filter pole locations with constraints on the filter group-delay. The PCLS algorithm of Selesnick, Lang and Burrus was reviewed in Section 8.1.2. At each iteration of the PCLS optimisation the Octave function *parallel_allpass_socp_mmse* optimises the filter response subject to the current constraints. The filter specification is

```

```

The final filter response is shown in Figure 10.35 and Figure 10.36.

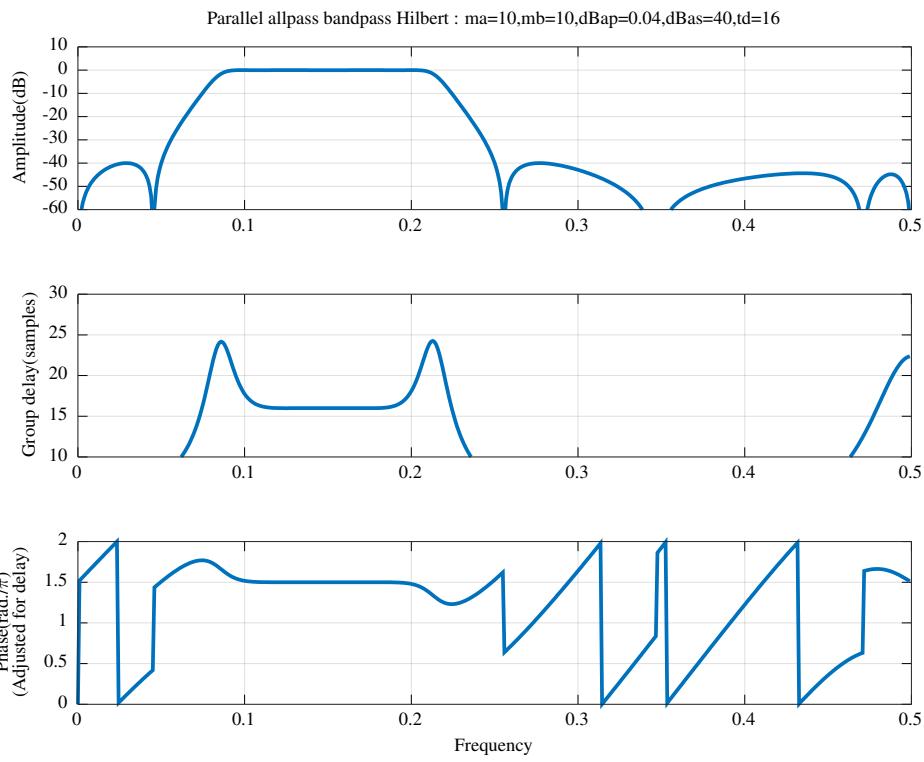

Figure 10.35: Band-pass Hilbert filter implemented as the difference of two all-pass filters : Response after PCLS SOCP optimisation

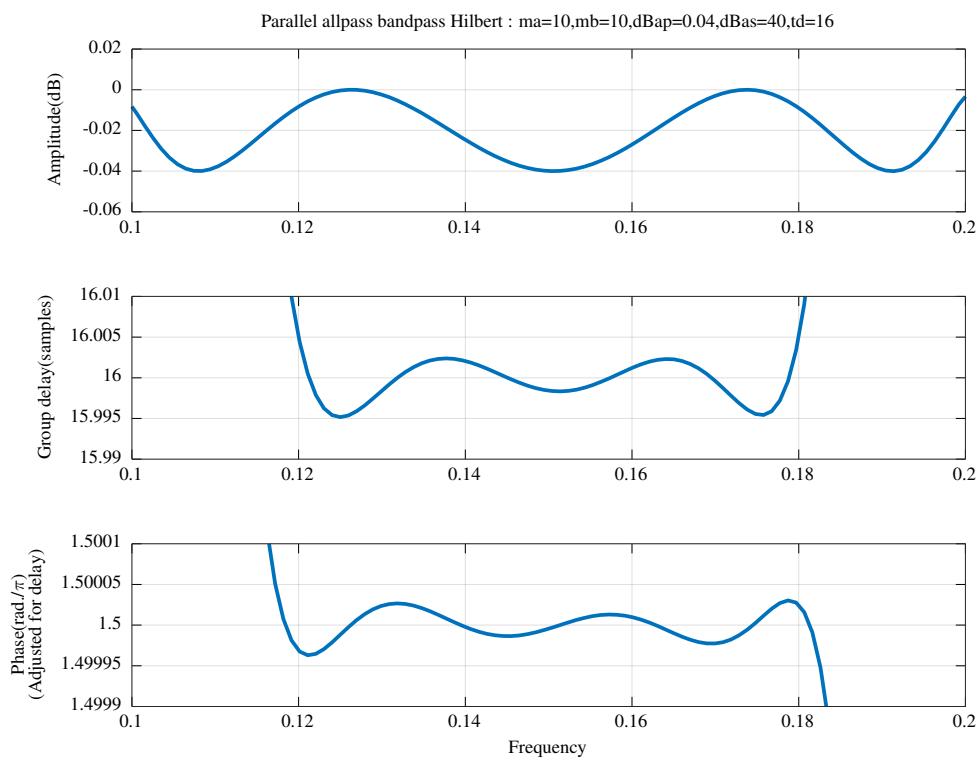

Figure 10.36: Band-pass Hilbert filter implemented as the difference of two all-pass filters : Pass-band response after PCLS SOCP optimisation

10.2.4 Design of an IIR filter as the sum of a delay and an all-pass filter represented in pole-zero form

Kunold [55] suggests realisation of a low-pass filter with flat pass-band delay by the parallel combination of a wave-digital lattice filter and a pure delay. The parallel fixed delay means that the all-pass filter phase change during the pass-band to stop-band transition of the overall amplitude response must result in a large peak in the group delay response over that transition band.

Design of an IIR filter as the sum of a delay and an all-pass filter represented in pole-zero form using SOCP

The Octave script *parallel_allpass_delay_socp_slb_test.m* uses the SeDuMi SOCP solver to design a low-pass filter consisting of an all-pass filter in parallel with a delay. The script calls the Octave function *parallel_allpass_delay_slb* to perform the PCLS design of the filter in terms of the all-pass filter pole locations. The PCLS algorithm of *Selesnick, Lang and Burrus* was reviewed in Section 8.1.2. At each iteration of the PCLS optimisation the Octave function *parallel_allpass_delay_socp_mmse* optimises the filter response subject to the current constraints. The filter specification is

```
tol=1e-05 % Tolerance on coefficient update vector
ctol=1e-08 % Tolerance on constraints
n=1000 % Frequency points across the band
m=12 % Allpass filter denominator order
V=0 % Allpass filter no. of real poles
Q=12 % Allpass filter no. of complex poles
R=1 % Allpass filter decimation
DD=11 % Parallel delay
fap=0.15 % Pass band amplitude response edge
dBap=0.500000 % Pass band amplitude response ripple
Wap=1 % Pass band amplitude response weight
fas=0.2 % Stop band amplitude response edge
dBas=66.000000 % Stop band amplitude response ripple
Was=100000 % Stop band amplitude response weight
rho=0.992188 % Constraint on allpass pole radius
```

There are no group delay constraints.

The initial allpass filter was designed by the Octave script *tarczynski_parallel_allpass_delay_test.m* using the *WISE* method described in Section 8.1.5. The response of the initial filter is shown in Figure 10.37 and the pole-zero plot of the initial filter is shown in Figure 10.38.

The final filter response is shown in Figure 10.39 with pass-band and stop-band details shown in Figure 10.40. The pole-zero plot of the all-pass branch of the filter is shown in Figure 10.41. The denominator polynomial of the final all-pass filter is

```
Da1 = [ 1.0000000000, -0.5307296401, 0.3599059935, 0.1921419524, ...
        0.0371422479, -0.0535791305, -0.0707542780, -0.0412439222, ...
        -0.0028810669, 0.0193707089, 0.0214887626, 0.0129398879, ...
        0.0044752288 ]';
```

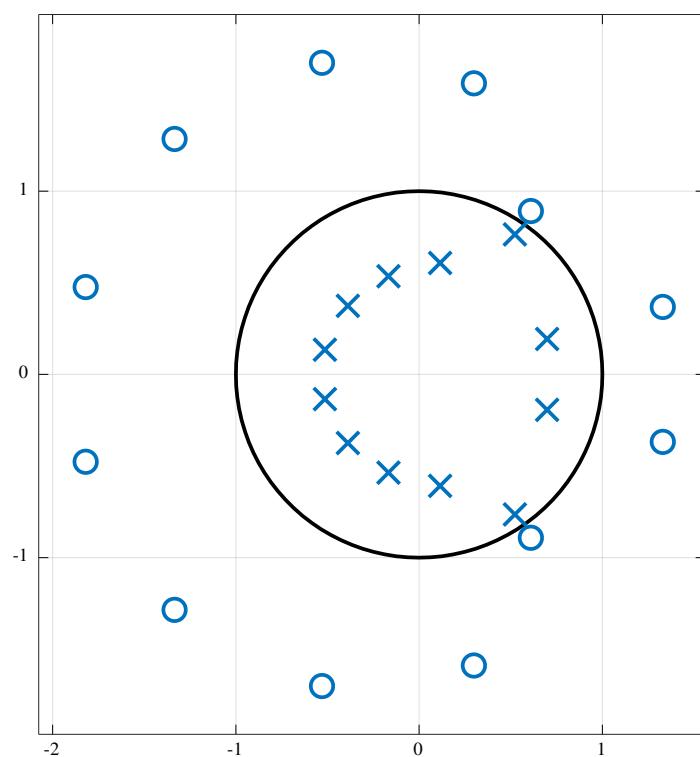

Figure 10.41: Parallel delay and all-pass filter : Pole-zero plot of the all-pass filter branch after PCLS SOCP optimisation

Design of an IIR filter as the sum of a delay and an all-pass filter represented in pole-zero form using SQP

The Octave script *parallel_allpass_delay_sqp_slb_test.m* repeats the design example of Section 10.2.4 with the SQP solver. The script calls the Octave function *parallel_allpass_delay_slb* to perform the PCLS design of the filter in terms of the all-pass filter pole locations. At each iteration of the PCLS optimisation the Octave function *parallel_allpass_delay_sqp_mmse* optimises the filter response subject to the current constraints. The filter specification is

```
tol=1e-05 % Tolerance on coefficient update vector
ctol=3e-07 % Tolerance on constraints
n=1000 % Frequency points across the band
m=12 % Allpass filter denominator order
V=0 % Allpass filter no. of real poles
Q=12 % Allpass filter no. of complex poles
R=1 % Allpass filter decimation
DD=11 % Parallel delay
fap=0.15 % Pass band amplitude response edge
dBap=0.050000 % Pass band amplitude response ripple
Wap=1 % Pass band amplitude response weight

10.2.5 Design of an IIR filter as the polyphase decomposition into two all-pass filters each represented in pole-zero form

The IIR filter of Equation 10.1 can be represented in “polyphase” form [92, 93] as

$$H(z) = \frac{1}{R} \sum_{k=0}^{R-1} z^{-k} A_k(z^R) \quad (10.2)$$

Where the A_k are all-pass filters. In the following I consider an example with $R = 2$, in other words, a half-band decimation filter suitable for use in an efficient half-band filter-bank. The Octave functions *parallel_allpassP* and *parallel_allpassAsq* support the calculation of the phase and squared magnitude response, respectively, of the polyphase combination of two all-pass filters with $R = 2$.

Design of an IIR filter as the polyphase decomposition into two all-pass filters each represented in pole-zero form with no constraints on the group delay

The Octave script *polyphase_allpass_socp_slb_test.m* calls the Octave function *parallel_allpass_slb* to design a low-pass filter composed of the polyphase combination of two parallel all-pass filters in terms of the allpass filter pole locations. The response of the filter is optimised with the PCLS algorithm described in Section 8.1.2. The filter specification is:

```

polyphase=1 % Use polyphase combination
tol=0.0001 % Tolerance on coefficient update vector
ctol=1e-09 % Tolerance on constraints
n=500 % Frequency points across the band
ma=11 % Allpass model filter A denominator order
K=100 % Scale factor

```

As in Section 10.2.3, the script does not optimise for a flat filter group delay.

The initial parallel all-pass filters were designed by the Octave script *tarczynski_polyphase_allpass_test.m* using the *WISE* method described in Section 8.1.5. In this case the script has *flat_delay = false*. The response of the initial filter is shown in Figure 10.45. After PCLS optimisation with the *SeDuMi* SOCP solver the response is shown in Figure 10.46 and Figure 10.47. The denominator polynomials of the two all-pass filters are

```

Da1 = [ 1.0000000000, 0.0000000000, 1.5814571203, 0.0000000000, ...

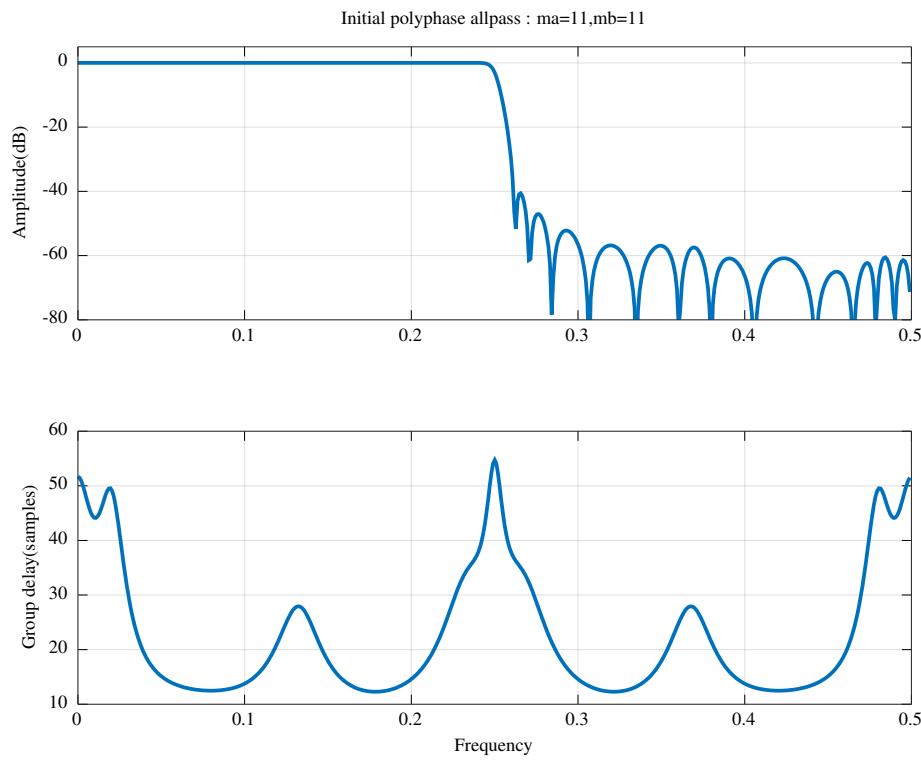

Figure 10.45: Polyphase combination of allpass filters : Initial response found with the WISE barrier function

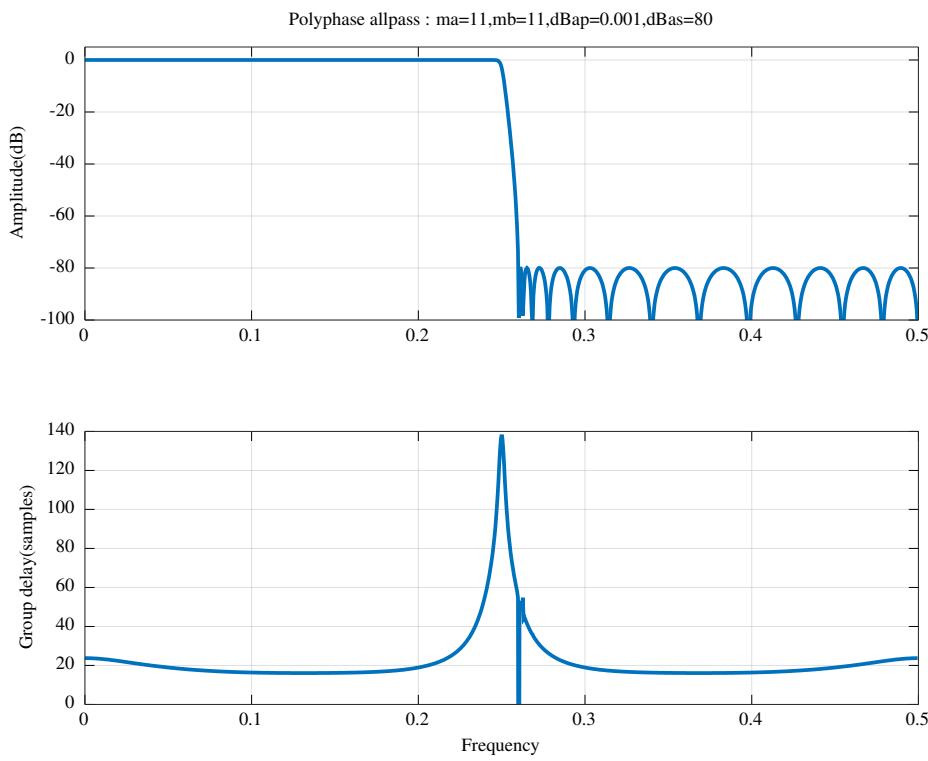

Figure 10.46: Polyphase combination of two allpass filters : Response after PCLS SOCP optimisation

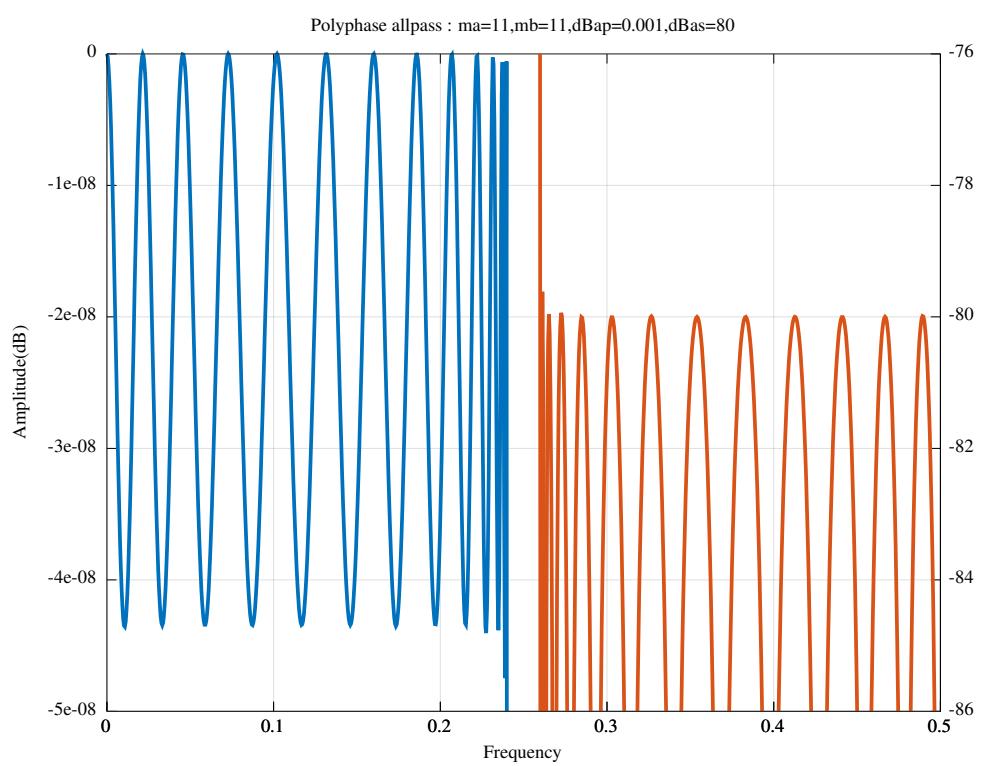

Figure 10.47: Polyphase combination of two allpass filters : Detail of response after PCLS SOCP optimisation

Design of an IIR filter as the polyphase decomposition into two all-pass filters each represented in pole-zero form with constraints on the group delay

The Octave script *polyphase_allpass_socp_slb_flat_delay_test.m* calls the Octave function *parallel_allpass_slb* to design a low-pass filter composed of the polyphase combination of two parallel all-pass filters in terms of the all-pass filter pole locations. The response of the filter is optimised with the PCLS algorithm described in Section 8.1.2. The filter specification is:

```

polyphase=1 % Use polyphase combination
tol=0.0001 % Tolerance on coefficient update vector
ctol=1e-07 % Tolerance on constraints
n=500 % Frequency points across the band
ma=11 % Allpass model filter A denominator order
Va=1 % Allpass model filter A no. of real poles
Qa=10 % Allpass model filter A no. of complex poles
Ra=2 % Allpass model filter A decimation
mb=11 % Allpass model filter B denominator order
Vb=1 % Allpass model filter B no. of real poles
Qb=10 % Allpass model filter B no. of complex poles
Rb=2 % Allpass model filter B decimation
fap=0.22 % Pass band amplitude response edge
dBap=0.000005 % Pass band amplitude response ripple
Wap=0 % Pass band amplitude response weight
fas=0.28 % Stop band amplitude response edge
dBas=62.000000 % Stop band amplitude response ripple
Was=500 % Stop band amplitude response weight
ftp=0.22 % Pass band group delay response edge
td=22.02 % Pass band nominal group delay
tdr=0.08 % Pass band nominal group delay ripple
Wtp=1 % Pass band group delay response weight
rho=0.968750 % Constraint on allpass pole radius

```

In this case the script does optimise for a flat filter group delay across the pass band. The nominal pass-band group delay was found by trial-and-error.

The initial parallel allpass filters were designed by the Octave script *tarczynski_polyphase_allpass_test.m* using the WISE method described in Section 8.1.5. In this case the script has *flat_delay = true*. The response of the initial filter is shown in Figure 10.48. After PCLS optimisation with the *SeDuMi* SOCP solver the response is shown in Figure 10.49. The pass band response is shown in Figure 10.50. The denominator polynomials of the two all-pass filters are

```

Da1 = [ 1.0000000000, 0.0000000000, -0.0212682116, -0.0000000000, ...

10.3 Design of an IIR Schur lattice filter

There is a large literature describing adaptive IIR lattice filters. For example, *Regalia* [108] describes adaptive IIR lattice filter algorithms with $\mathcal{O}(N)$ complexity. The lattice structure has the advantage that the allpass “reflection” coefficients, k_i , have a simple filter stability criterion: $|k_i| < 1$ (see, for example, *Vaidyanathan and Mitra* [114]). This section describes the PCLS design of the squared magnitude, phase and group delay responses of one-multiplier and normalised scaled IIR Schur lattice filters by SOCP and SQP optimisation of the lattice coefficients. The calculation of the Schur lattice filter squared-magnitude, phase and group delay responses and gradients is calculated in three steps:

1. calculate the state variable representation of the lattice filter and the gradients of the state variable matrixes with respect to each of the lattice coefficients
2. calculate the lattice filter complex frequency response and gradients
3. calculate the lattice filter squared magnitude, phase and group delay responses and gradients

Chapter 5 reviews the Schur decomposition of an IIR transfer function into an IIR tapped-lattice structure. Algorithm 5.4 shows the factorisation of the state variable description of the *one-multiplier* lattice filter. Algorithm 5.6 shows the factorisation of the state variable description of the *normalised-scaled* lattice filter. Section 1.9.4 reviews the sensitivities of the complex transfer function with respect to the state variable coefficients. Appendix H shows the gradients of the squared-magnitude, phase and group delay responses with respect to the components of the state variable matrixes. The state-transition matrix, A , generated by Algorithm 5.4 or Algorithm 5.6 is lower Hessenberg. The matrix resolvent, $(zI - A)^{-1}$ is calculated by direct matrix inversion rather than *Leverrier*’s algorithm (see Algorithm 1.6). Xu Zhong [170] gives an algorithm that calculates the inverse of a lower Hessenberg matrix. That algorithm is implemented in Octave as the function *zhong_inverse.m* and, for a matrix with complex elements, in the *oct-file* *complex_zhong_inverse.cc*. The Octave function *Abcd2H*, exercised by the Octave script *Abcd2H_test.m*, calculates the response of a state variable filter and the gradients of the complex response with respect to frequency and with respect to the components of the state variable matrixes. The Octave function *Abcd2H* assumes that the components of the state variable matrixes are first order combinations of the lattice coefficients. In other words, *Abcd2H* does not support gradients with respect to the square-roots of the k and c lattice coefficients derived in Section 5. The results of this section are intended to be used in the following Part III to optimise the choice of fixed-point lattice coefficients. The k and c lattice coefficients of an “exact” transfer function can be calculated from a transfer function optimised in the *gain-pole-zero* form.

10.3.1 Design of an IIR one-multiplier Schur lattice low-pass filter using SOCP

The Octave script *schurOneMlattice_socp_slb_lowpass_test.m* implements the design of a lowpass IIR one-multiplier Schur lattice filter using the *SeDuMi* SOCP solver with PCLS constraints. The filter specification is similar to that of the *Deczky3* gain-pole-zero SQP and SOCP optimisation examples in Sections 8.2.3 and 9.4:

```
tol=1e-06 % Tolerance on coefficient update vector
ctol=1e-06 % Tolerance on constraints
n=400 % Frequency points across the band
length(c0)=11 % Tap coefficients
length(k0~=0)=10 % Num. non-zero all-pass coef.s
rho=0.992188 % Constraint on allpass coefficients
fap=0.15 % Amplitude pass band edge
dBap=0.1 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
ftp=0.25 % Delay pass band edge
tp=10 % Nominal pass band filter group delay
tpr=0.02 % Delay pass band peak-to-peak ripple
Wtp=1 % Delay pass band weight
fas=0.3 % Amplitude stop band edge
dBas=38 % Amplitude stop band peak-to-peak ripple
Was=100 % Amplitude stop band weight
```

The initial filter is the “IPZS-1” filter of Section 8.2.3. Figures 10.51 and 10.52 show the overall and passband response after SOCP PCLS optimisation. Figure 10.53 shows the pole-zero plot of the resulting filter after SOCP PCLS optimisation.

The PCLS SOCP optimised Schur one-multiplier all-pass lattice and numerator tap coefficients of the low-pass filter are:

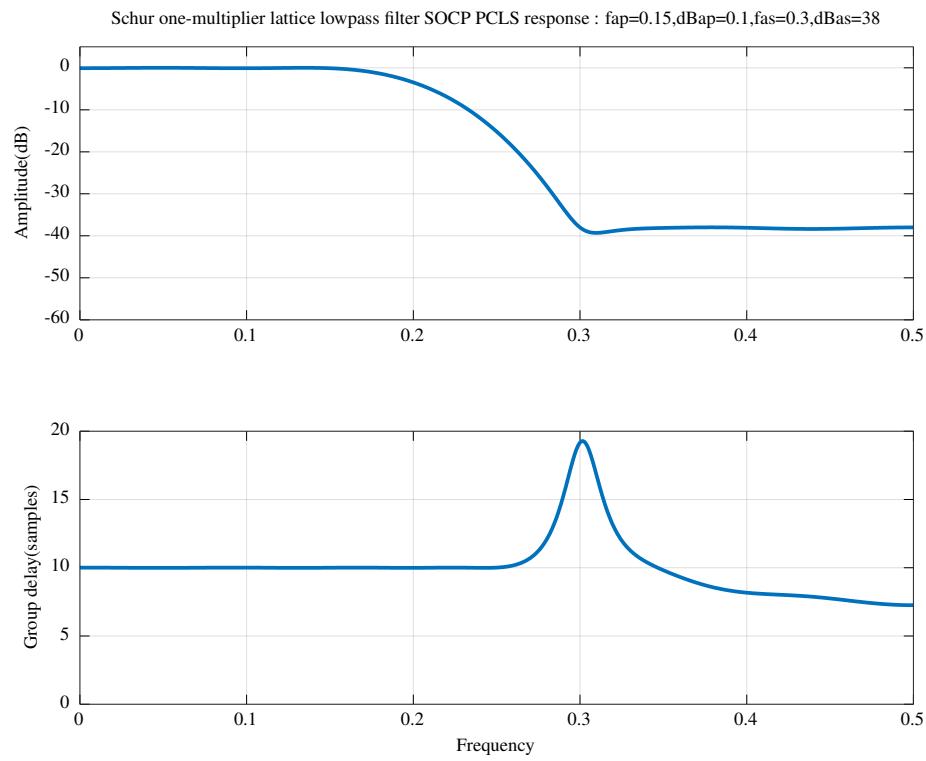

Figure 10.51: Schur one-multiplier lattice lowpass filter : response after PCLS SOCP optimisation

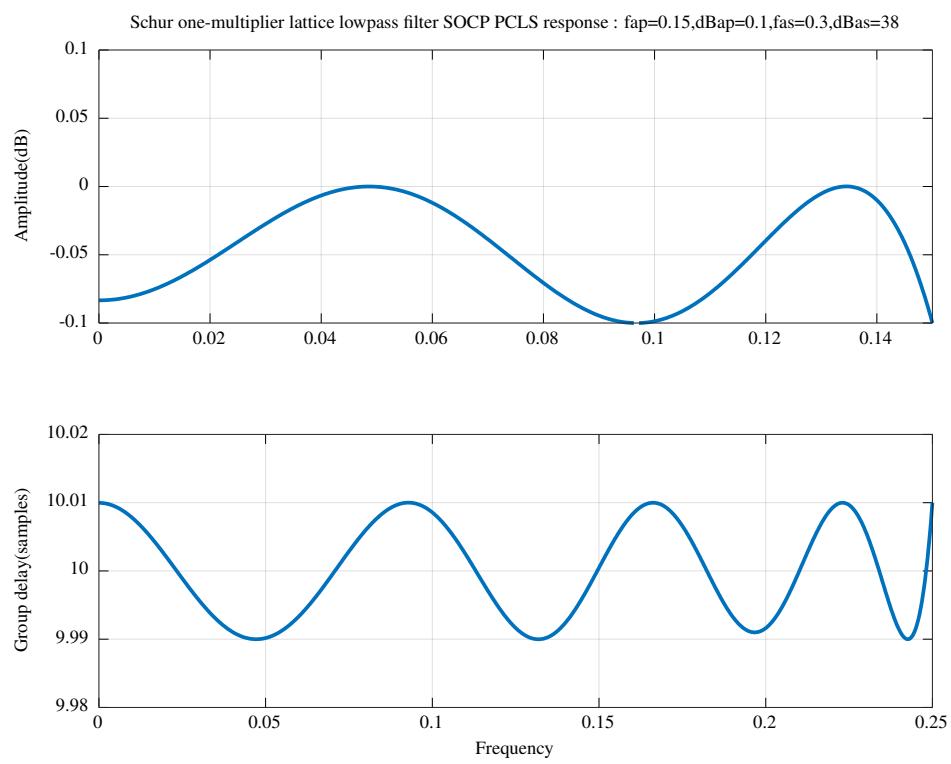

Figure 10.52: Schur one-multiplier lattice lowpass filter : passband response after PCLS SOCP optimisation

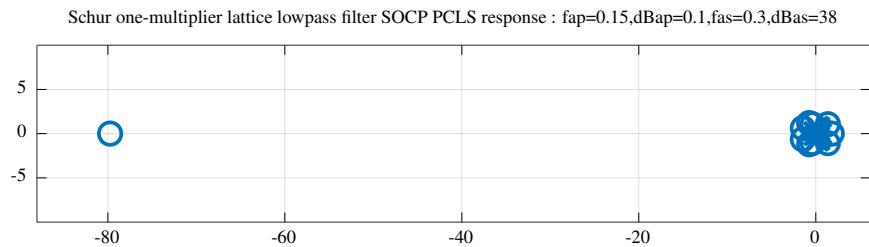

Figure 10.53: Schur one-multiplier lattice lowpass filter : pole-zero plot after PCLS SOCP optimisation

```

k2 = [ -0.6632505797,    0.6513340268,   -0.5324878348,    0.3544242862, ...
       -0.1741303958,    0.0474956383,   -0.0000000000,    0.0000000000, ...
       0.0000000000,   -0.0000000000 ];

epsilon2 = [ -1, -1, -1, -1, ...
             1, -1,  1, -1, ...
            -1,  1 ];

p2 = [  1.0208594831,    0.4593466507,   0.9996621207,    0.5521424987, ...
       0.7997512923,    0.9535805295,   1.0000000000,    1.0000000000, ...
       1.0000000000,   1.0000000000 ];

c2 = [  0.4474541260,    0.8866579094,   0.0987164293,   -0.1374112187, ...
       -0.0510594356,    0.0175765251,   0.0222765103,   0.0003806859, ...
       -0.0078413107,   -0.0035065056,  -0.0000427363 ];

```

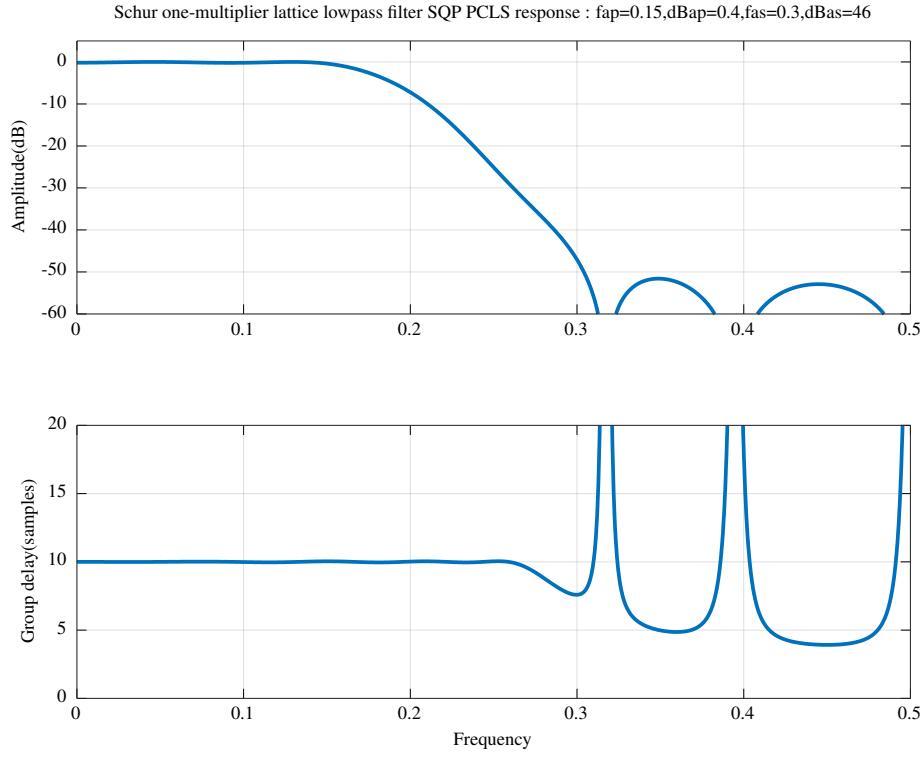

Figure 10.54: Schur one-multiplier lattice lowpass filter : response after SQP PCLS optimisation

10.3.2 Design of an IIR one-multiplier Schur lattice low-pass filter using SQP

The Octave script *schurOneMlattice_sqp_slb_lowpass_test.m* implements the design of a lowpass IIR one-multiplier Schur lattice filter with SQP and PCLS. The specification of the filter is:

```

tol=4e-05 % Tolerance on coefficient update vector
ctol=4e-05 % Tolerance on constraints
n=400 % Frequency points across the band
length(c0)=11 % Tap coefficients
sum(k0~=0)=6 % Num. non-zero lattice coefficients
dmax=0.050000 % Constraint on norm of coefficient SQP step size
rho=0.992188 % Constraint on lattice coefficient magnitudes
fap=0.15 % Amplitude pass band edge
dBap=0.4 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
ftp=0.25 % Delay pass band edge
tp=10 % Nominal pass band filter group delay
tpr=0.08 % Delay pass band peak-to-peak ripple
Wtp_mmse=0.1 % Delay pass band weight for MMSE
Wtp_pcls=1 % Delay pass band weight for PCLS
fas=0.3 % Amplitude stop band edge
dBas=46 % amplitude stop band peak-to-peak ripple
Was_mmse=1e+08 % Amplitude stop band weight for MMSE
Was_pcls=1e+08 % Amplitude stop band weight for PCLS

```

The initial filter is the “IPZS-1” of Section 8.2.3. As for the examples of Chapter 8 the SQP BFGS update is initialised by the diagonal of the Hessian matrix of the squared error. The diagonals of the Hessian matrixes of the squared-magnitude, phase and group delay are given in Appendix H.

Figures 10.54 and 10.55 show the overall and passband response of the filter after SQP PCLS optimisation. Figure 10.56 shows the pole-zero plot of the filter after SQP PCLS optimisation.

The SQP PCLS optimised Schur one-multiplier all-pass lattice and numerator tap coefficients of the low-pass filter are:

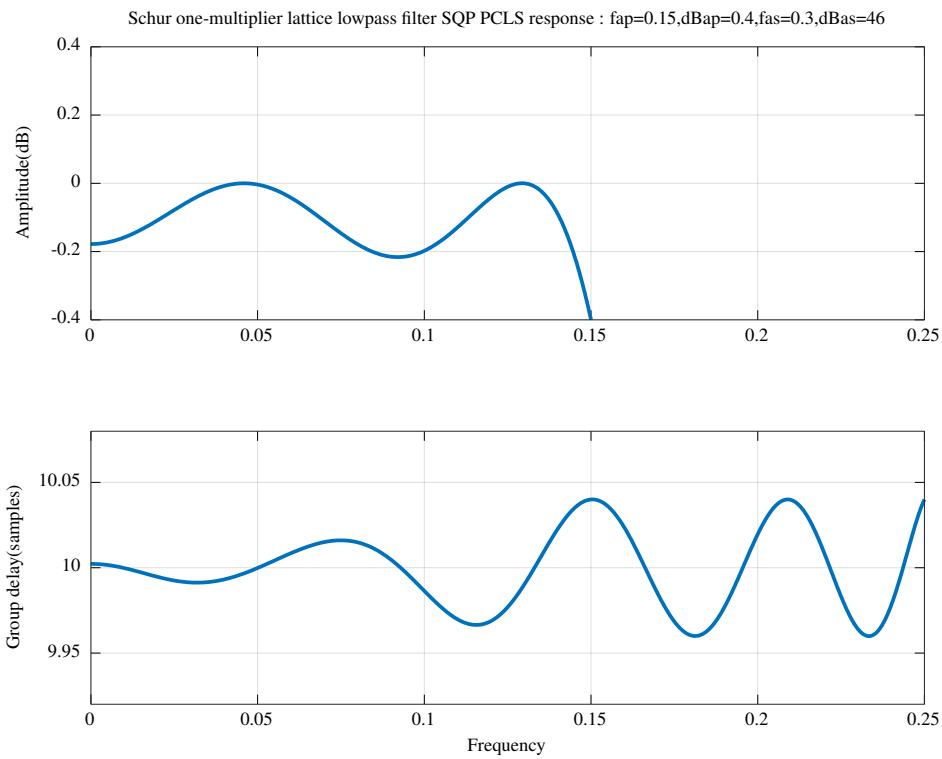

Figure 10.55: Schur one-multiplier lattice lowpass filter : passband response after SQP PCLS optimisation

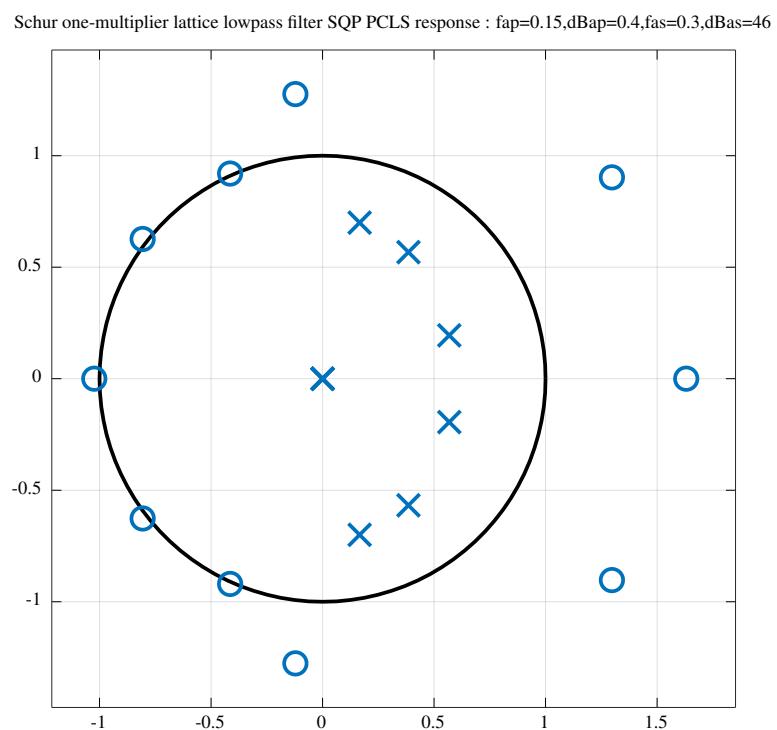

Figure 10.56: Schur one-multiplier lattice lowpass filter : pole-zero plot after SQP PCLS optimisation

```

k2 = [ -0.7375771181,    0.7329492530,   -0.6489740765,    0.4943363006, ...
       -0.2824593372,    0.0878212134,   -0.0000000000,    0.0000000000, ...
       0.0000000000,    0.0000000000 ];

epsilon2 = [ -1, -1, -1, -1, ...
             -1, -1,  1, -1, ...
             -1, -1 ];

p2 = [  1.5591179441,    0.6059095195,   1.5434899280,    0.7121418051, ...
       1.2242208323,    0.9157168850,   1.0000000000,    1.0000000000, ...
       1.0000000000,    1.0000000000 ];

c2 = [  0.2287455707,    0.7274997803,   0.1030199742,   -0.0659731942, ...

       -0.0023124161,   -0.0090627662,   -0.0052625492 ];

```

10.3.3 Design of an IIR one-multiplier Schur lattice band-pass filter using SQP

The Octave script *schurOneMlattice_sqp_slb_bandpass_test.m* implements the design of a band-pass IIR one-multiplier Schur lattice filter with SQP and PCLS. The specification of the filter is:

```

tol_mmse=2e-05 % Tolerance on coef. update for MMSE
tol_pcls=1e-05 % Tolerance on coef. update for PCLS
ctol=1e-05 % Tolerance on constraints
n=500 % Frequency points across the band
length(c0)=21 % Tap coefficients
sum(k0~=0)=10 % Num. non-zero all-pass coef.s
dmax=0.050000 % Constraint on norm of coefficient SQP step size
rho=0.992188 % Constraint on allpass coefficients
fapl=0.1 % Amplitude pass band lower edge
fapu=0.2 % Amplitude pass band upper edge
dBap=2 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
ftpl=0.09 % Delay pass band lower edge
ftpu=0.21 % Delay pass band upper edge
tp=16 % Nominal passband filter group delay
tpr=0.08 % Delay pass band peak-to-peak ripple
Wtp_mmse=5 % Delay pass band weight (MMSE)
Wtp_pcls=1 % Delay pass band weight (PCLS)
fasl=0.05 % Amplitude stop band lower edge
fasu=0.25 % Amplitude stop band upper edge
dBas=36 % Amplitude stop band peak-to-peak ripple
Wasl_mmse=100000 % Ampl. lower stop band weight (MMSE)
Wasu_mmse=500000 % Ampl. upper stop band weight (MMSE)
Wasl_pcls=100000 % Ampl. lower stop band weight (PCLS)
Wasu_pcls=500000 % Ampl. upper stop band weight (PCLS)

```

The initial filter is that of the Octave script *iir_sqp_slb_bandpass_test.m*, as shown in Section 8.2.6. The denominator polynomial of the filter has coefficients in z^2 only.

Figure 10.57 shows the overall response of the band-pass filter after SQP MMSE optimisation. Figures 10.58 and 10.59 show the overall and passband response of the band-pass filter after SQP PCLS optimisation. Figure 10.60 shows the pole-zero plot of the band-pass filter after SQP PCLS optimisation.

The SQP PCLS optimised Schur one-multiplier allpass lattice and numerator tap coefficients of the band-pass filter are:

```

k2 = [ 0.0000000000, 0.6627692632, 0.0000000000, 0.4986334640, ...

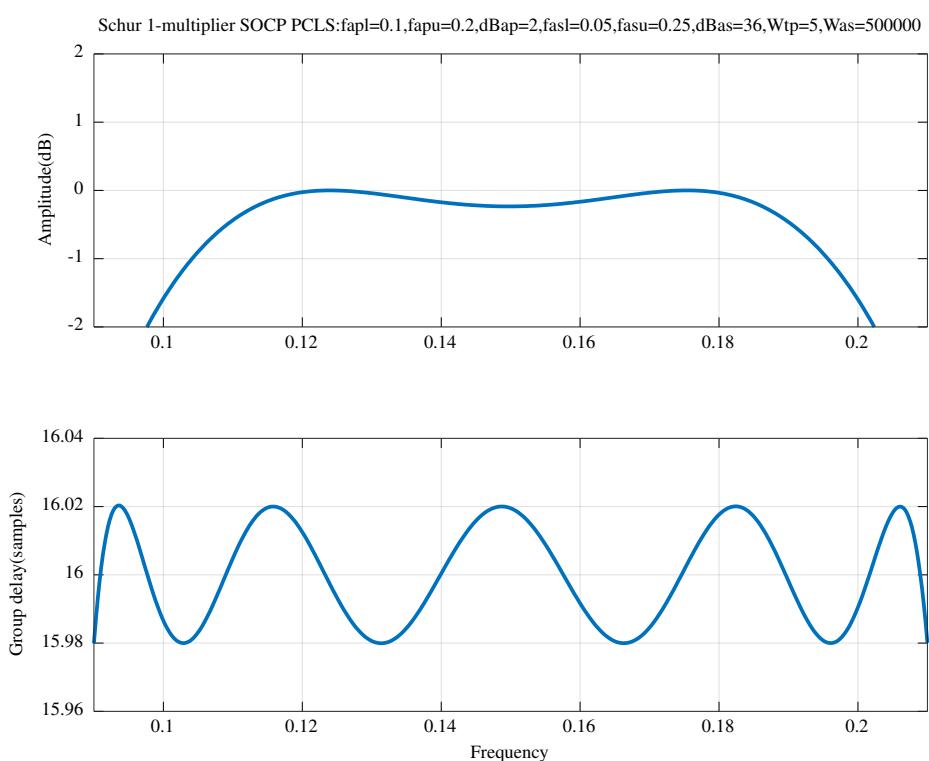

Figure 10.62: Schur one-multiplier lattice band-pass filter : passband response after SOCP PCLS optimisation

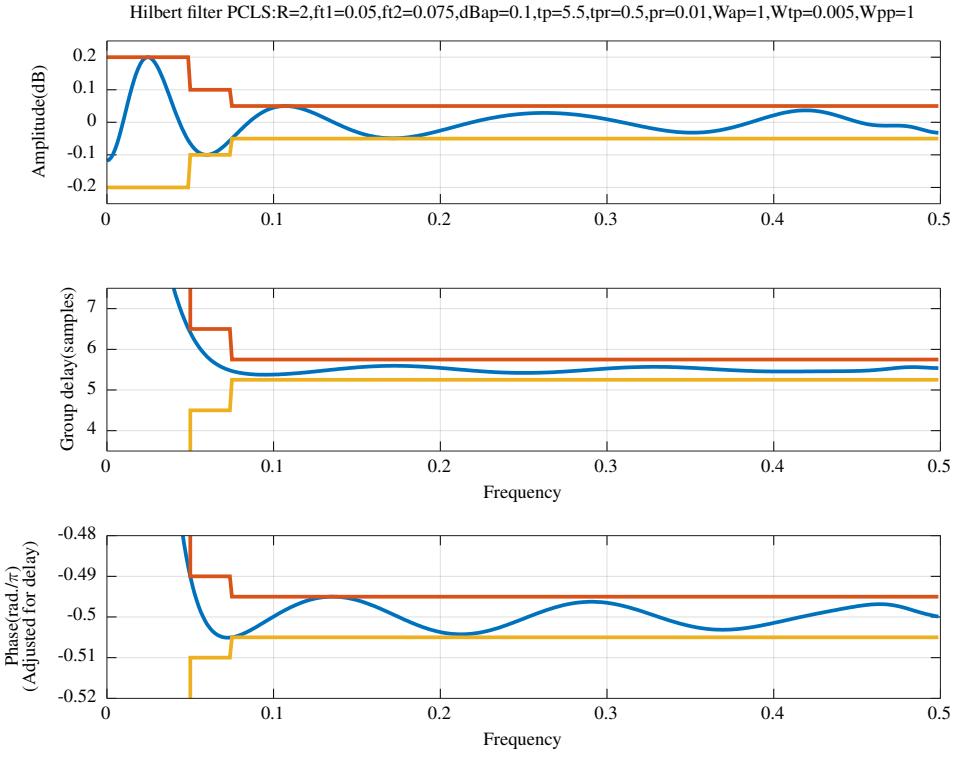

Figure 10.63: Schur one-multiplier lattice Hilbert filter : response after SQP PCLS optimisation

10.3.4 Design of an IIR one-multiplier Schur lattice Hilbert filter using SQP

The Octave script *schurOneMlattice_sqp_slb_hilbert_test.m* implements the design of an IIR one-multiplier Schur lattice Hilbert filter with SQP and PCLS. The specification of the filter is:

```

tol=0.0001 % Tolerance on coefficient update vector
ctol=0.0001 % Tolerance on constraints
n=400 % Frequency points across the band
dmax=0.100000 % Constraint on norm of coefficient SQP step size
rho=0.999900 % Constraint on lattice coefficient magnitudes
ft1=0.05 % First transition band [0,ft1]
ft2=0.075 % Second transition band [ft1,ft2]
dBap=0.1 % Amplitude pass band peak-to-peak ripple
Wat=0.05 % Amplitude transition band weight
Wap=1 % Amplitude pass band weight
tp=5.5 % Nominal pass band filter group delay
tpr=0.5 % Pass band filter group delay peak-to-peak ripple
Wtp=0.005 % Pass band group delay weight
pr=0.01 pi/2 % Pass band peak-to-peak phase ripple
Wpp=1 % Pass band phase weight

```

The initial filter is that of the Octave script *iir_sqp_slb_hilbert_test.m* designed by the method of Tarczynski et. al. with the Octave script *tarczynski_hilbert_test.m*, as shown in Section 8.2.7. The denominator polynomial of the filter has coefficients in z^2 only. Figure 10.63 shows the response of the Hilbert filter after SQP PCLS optimisation. The phase response shown has been adjusted by the nominal group delay, $\omega\tau_p$. The values shown on the phase axis of the phase response plot are multiples of $\frac{\pi}{2}$. Figure 10.64 shows the pole-zero plot of the Hilbert filter after SQP PCLS optimisation.

The SQP PCLS optimised Schur one-multiplier all-pass lattice and numerator tap coefficients of the Hilbert filter are:

```

k2 = [ 0.0000000000, -0.9135081373, 0.0000000000, 0.5546428088, ...
        0.0000000000, -0.0966755726, 0.0000000000, 0.0007462344, ...
        0.0000000000, -0.0020582170, 0.0000000000, 0.0015840384 ];

epsilon2 = [ 0, -1, 0, -1, ...
            0, 1, 0, -1, ...
            0, 1, 0, -1 ];

```

Hilbert filter PCLS:R=2,ft1=0.05,ft2=0.075,dBap=0.1,tp=5.5,tpr=0.5,pr=0.01,Wap=1,Wtp=0.005,Wpp=1

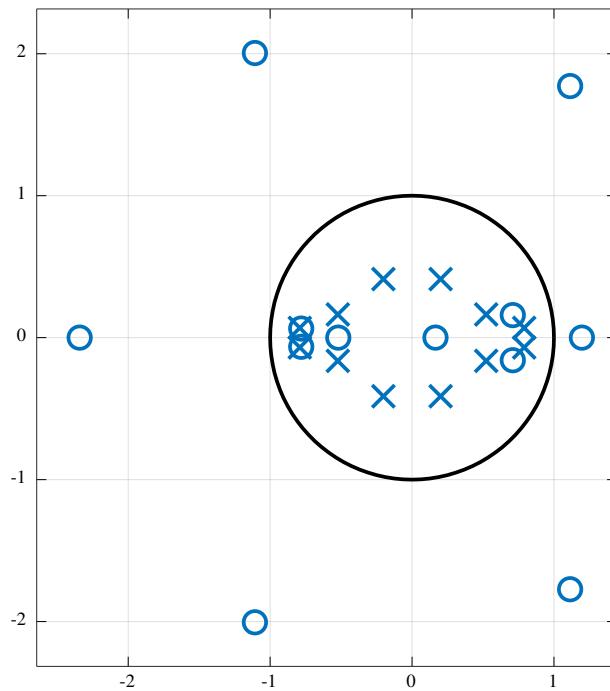

Figure 10.64: Schur one-multiplier lattice Hilbert filter : pole-zero plot after SQP PCLS optimisation

```
p2 = [ 2.2748006743, 2.2748006743, 0.4836328777, 0.4836328777, ...
        0.9036013963, 0.9036013963, 0.9956211211, 0.9956211211, ...
        0.9963643653, 0.9963643653, 0.9984172142, 0.9984172142 ];
```

```
c2 = [ 0.0435189928, 0.0508921401, 0.2428519502, 0.2882277493, ...

        -0.1639093080, -0.0790058477, -0.0435858016, -0.0252833113, ...
        -0.0155222724 ];
```

Alternatively, the Octave script *schurOneMlattice_socp_slb_hilbert_test.m* implements the design of an IIR one-multiplier Schur lattice Hilbert filter with SOCP and PCLS.

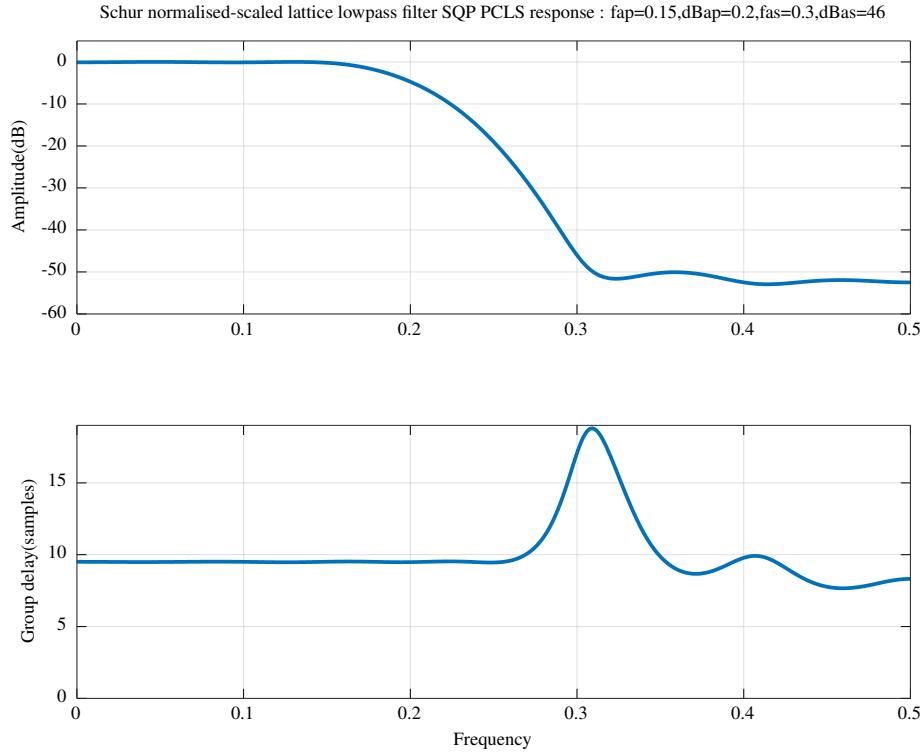

Figure 10.65: Schur normalised-scaled lattice lowpass filter : response after SQP PCLS optimisation

10.3.5 Design of an IIR Schur normalised-scaled lattice low-pass filter using SQP

The Octave script *schurNSlattice_sqp_slb_lowpass_test.m* implements the design of a lowpass IIR normalised-scaled structure Schur lattice filter with SQP and PCLS. The filter coefficients are allowed to vary independently and the resulting filter is not, in fact, normalised-scaled. The specification of the filter is:

```

tol_mmse=0.001 % Tolerance on coefficient update vector for MMSE
tol_pcls=1e-05 % Tolerance on coefficient update vector for PCLS
ctol=1e-05 % Tolerance on constraints
n=400 % Frequency points across the band
sxx_symmetric=0 % Enforce s02=-s20 and s22=s00
dmax=0.050000 % Constraint on norm of coefficient SQP step size
rho=0.999990 % Constraint on lattice coefficient magnitudes
fap=0.15 % Amplitude pass band edge
dBap=0.2 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
ftp=0.25 % Delay pass band edge
tp=9.5 % Nominal pass band filter group delay
tpr=0.1 % Delay pass band peak-to-peak ripple
Wtp_mmse=0.01 % Delay pass band weight for MMSE
Wtp_pcls=0.1 % Delay pass band weight for PCLS
fas=0.3 % Amplitude stop band edge
dBas=46 % amplitude stop band peak-to-peak ripple
Was_mmse=10000 % Amplitude stop band weight for MMSE
Was_pcls=1e+06 % Amplitude stop band weight for PCLS

```

The initial filter is the “IPZS-1” of Section 8.2.3. As for the examples of Chapter 8 the SQP BFGS update is initialised by the diagonal of the Hessian matrix of the squared error.

Figures 10.65 and 10.66 show the overall and passband response of the filter after SQP PCLS optimisation. Figure 10.67 shows the pole-zero plot of the filter after SQP PCLS optimisation.

The SQP PCLS optimised Schur normalised-scaled all-pass lattice and numerator tap coefficients of the low-pass filter are:

```
s10_2 = [ 1.2139594722, 0.4304107448, -0.0657111892, -0.1192373087, ... ]
```

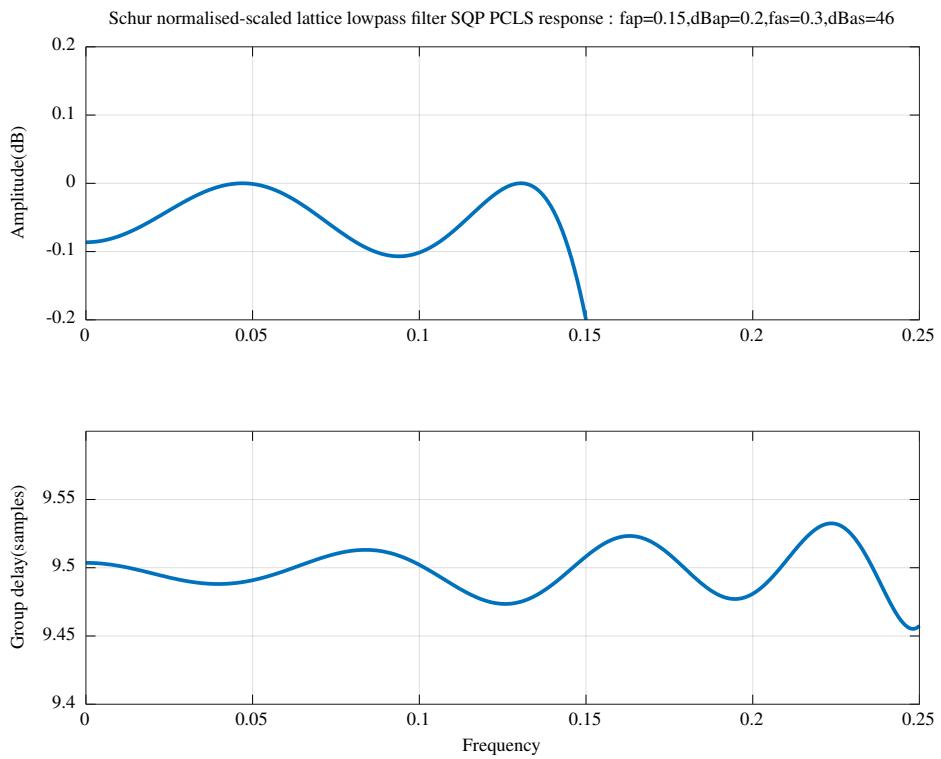

Figure 10.66: Schur normalised-scaled lattice lowpass filter : passband response after SQP PCLS optimisation

s00_2 = [ 0.7910940747,    0.6134643670,    0.7865221051,    0.8637318525, ...
0.9722121634,    0.9974928986,    1.0000000000,    1.0000000000, ...
1.0000000000,    1.0000000000 ];

s02_2 = [ 0.8659608955,   -0.7738763981,    0.6742136672,   -0.5215951382, ...
0.3939054507,   -0.2505521617,   -0.0000000000,   -0.0000000000, ...
-0.0000000000,   -0.0000000000 ];

s22_2 = [ 0.7710543378,    0.9130256682,    0.9672191922,    0.9355878268, ...
0.6110976455,    0.9990271218,    1.0000000000,    1.0000000000, ...
1.0000000000,    1.0000000000 ];

```

The diagonal of the state covariance matrix, K , of the optimised filter is:

```

diag(K) = [ 0.6029,      0.5846,      0.8568,      1.0115, ...
1.1926,      1.0839,      1.0000,      1.0000, ...
1.0000,      1.0000 ]';

```

The SQP loop for this example is called from the Octave function *schurNSlattice_sqp_mmse* exercised by the Octave script *schurNSlattice_sqp_mmse_test.m*. The *schurNSlattice_sqp_mmse* function includes code that forces $s_{02} = -s_{20}$ and $s_{22} = s_{00}$. In neither case does this function enforce normalised-scaling with the relations $s_{02} = \sqrt{1 - s_{00}^2}$ and $s_{22} = \sqrt{1 - s_{20}^2}$. For simplicity, I have assumed that all relationships between coefficients are linear.

10.3.6 Design of an IIR low-pass filter with parallel Schur one-multiplier all-pass lattice filters using SOCP

The Octave script *schurOneMPAlattice_socp_slb_lowpass_test.m* implements the design of a low-pass IIR filter composed of the sum of two parallel one-multiplier Schur lattice all-pass filters with SOCP and PCLS optimisation. The specification of the filter is:

```

tol=1e-07 % Tolerance on coefficient update vector
ctol=1e-07 % Tolerance on constraints
n=400 % Frequency points across the band
m1=11 % Allpass model filter 1 denominator order
m2=12 % Allpass model filter 2 denominator order
rho=0.992188 % Constraint on allpass coefficients
fap=0.125 % Amplitude pass band edge
dBap=0.1 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
Wat=0 % Amplitude transition band weight
fas=0.25 % Amplitude stop band edge
dBas=60 % amplitude stop band peak-to-peak ripple
Was=100 % Amplitude stop band weight
ftp=0.175 % Delay pass band edge
td=11.5 % Nominal pass band filter group delay
tdr=0.08 % Delay pass band peak-to-peak ripple
Wtp=2 % Delay pass band weight

```

The initial parallel all-pass filters were designed by the Octave script *tarczynski_parallel_allpass_test.m* (with *flat_delay = true*). These initial filters are those used in Section 10.2.3.

Figures 10.68 and 10.69 show the overall and passband responses of the filter after SOCP PCLS optimisation and Figure 10.70 shows the pole-zero plot of the filter. Figure 10.71 shows the coefficient sensitivity responses of the filter.

The low-pass filter SOCP PCLS optimised Schur one-multiplier all-pass lattice coefficients are:

```

A1k = [ 0.7710148931, -0.0879082413, -0.2675569191, -0.0636385348, ...
        -0.0589767502, 0.2446866951, -0.1439283785, -0.0042026127, ...
        0.1645512018, -0.1594766619, 0.0542388379 ];

Alepsilon = [ 1, 1, 1, 1, ...
             1, -1, 1, 1, ...
             1, 1, -1 ];

A2k = [ 0.3880312216, -0.2734888919, 0.1864488795, 0.1636111104, ...
        -0.0463361738, 0.0417241579, -0.2011467442, 0.1798135928, ...
        0.0053789583, -0.1784404051, 0.1504522278, -0.0552341933 ];

A2epsilon = [ 1, 1, 1, -1, ...
              1, -1, -1, -1, ...
              -1, -1, -1, 1 ];

```

10.4 Design of IIR filters with a sharp transition band by frequency response masking

10.4.1 Review of Frequency Response Masking digital filters

Frequency response masking (FRM) is a technique for designing digital filters with sharp transition bands. Given a prototype or “model” low-pass filter, $G(z)$, the filter $G(z^M)$ has a pass-band width and pass-band to stop-band transition width that is reduced by a factor M compared to the model low-pass filter and also has M images across the whole frequency band. The “masking” filter, $F(z)$ selects the required filter image frequency response. The resulting filter is $G(z^M)F(z)$, illustrated in Figure 10.76. This simple frequency response masking filter technique is only suitable for designing narrow-band filters. Lim [171] describes the design of digital filters with sharp transition bands with wider bandwidths using FIR model and masking filters. Lu and Hinamoto [160] describe the design of digital filters with an IIR model filter and FIR masking filters using a structure, shown in Figure 10.77, that is similar to Lim’s. The passband delay of $F_a(z)$ is D so that $F_c = z^{-D} - F_a(z)$ is complementary to $F_a(z)$.

Johansson and Wanhammar [50] describe design of frequency response masking filters with a model filter consisting of parallel all-pass filters, FIR masking filters and the structure shown in Figure 10.78. Johansson and Wanhammar specify a delay line in one arm of the model filter if approximately linear phase response is desired.

In the following I use Lim’s description of frequency response masking for the two cases shown in Figure 10.79 [171, Section III, Figure 4]. Figure 10.79a shows the response of a prototype filter a with frequency response, $F_a(\omega)$, having passband and

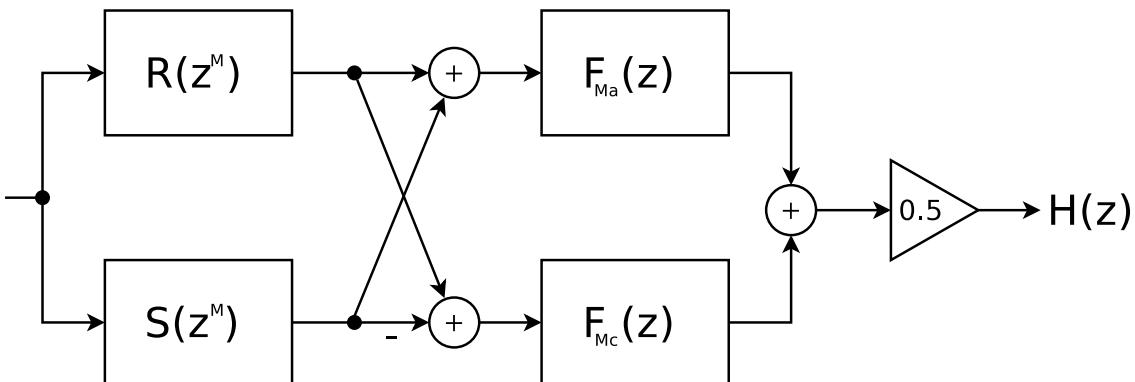

Figure 10.78: Johansson and Wanhammar’s frequency response masking filter structure

stopband edge frequencies of θ and ϕ respectively. Figure 10.79b shows the response of the complementary filter $F_c(z) = z^{-D} - F_a(z)$. Figure 10.79c shows the responses of the filters $F'_a(z) = F_a(z^M)$ and $F'_c(z) = F_c(z^M)$. Each response is aliased into M images across the frequency band. The aliased response of the model filter is masked by F_{M_a} and the aliased response of the complement to the model filter is masked by F_{M_c} . For example, in Figure 10.79d, F_{M_a} has passband and stopband edge frequencies of $\omega_{M_{ap}} = \frac{2m\pi+\theta}{M}$ and $\omega_{M_{as}} = \frac{2(m+1)\pi-\phi}{M}$ respectively. Here $\omega_{M_{ap}}$ includes the m 'th image band of the model filter and $\omega_{M_{as}}$ excludes the $m + 1$ 'th image band of the model filter. The complementary masking filter, F_{M_c} , has passband and stopband edge frequencies of $\omega_{M_{cp}} = \frac{2m\pi-\theta}{M}$ and $\omega_{M_{cs}} = \frac{2m\pi+\phi}{M}$ respectively so that the $m - 1$ 'th image of the complementary filter is included and the m 'th image is excluded. The resulting frequency response masking filter, shown in Figure 10.79e, has passband edge $\omega_p = \frac{2m\pi+\theta}{M}$ and stopband edge $\omega_s = \frac{2m\pi+\phi}{M}$. Alternatively, Figures 10.79f and 10.79g show the frequency response masking filter for which the passband edge is $\omega_p = \frac{2m\pi-\phi}{M}$ and the stopband edge is $\omega_s = \frac{2m\pi-\theta}{M}$. In this case the filter includes $m - 1$ images of the model filter and $m - 1$ images of the complementary filter.

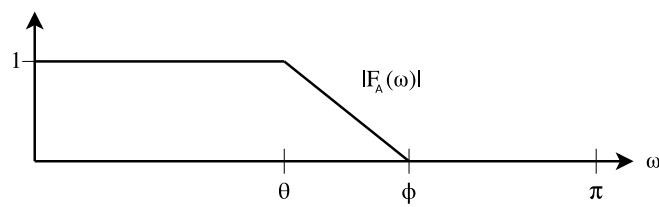

In order that $0 < \theta < \phi < \pi$ in Figure 10.79a, for Figure 10.79e

$$\begin{aligned} m &= \lfloor \frac{\omega_p M}{2\pi} \rfloor \\ \theta &= \omega_p M - 2m\pi \\ \phi &= \omega_s M - 2m\pi \end{aligned}$$

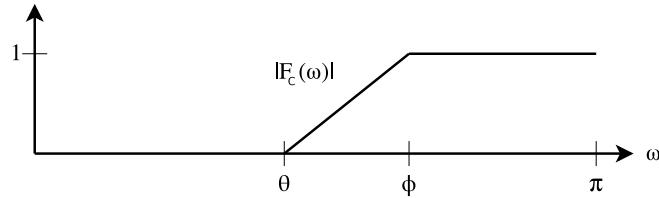

and for Figure 10.79g

$$\begin{aligned} m &= \lceil \frac{\omega_s M}{2\pi} \rceil \\ \theta &= 2m\pi - \omega_s M \\ \phi &= 2m\pi - \omega_p M \end{aligned}$$

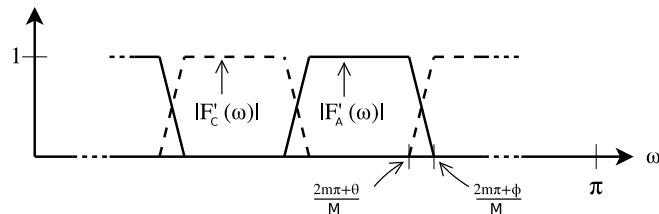

where $\lfloor x \rfloor$ and $\lceil x \rceil$ represent the largest integer less than x and the smallest integer larger than x respectively.

10.4.2 Design of an FRM digital filter with an IIR model filter consisting of a cascade of second-order sections using SOCP

In this section I follow Lu and Hinamoto [160, Section V] The FRM filter structure is shown in Figure 10.77. The model filter is an IIR filter of the form

$$F_a(z) = \frac{a(z)}{d(z)}$$

where

$$a(z) = \sum_{k=0}^n a_k z^{-k}$$

and $d(z)$ is a product of second order sections (with one first order section if r is odd)

$$d(z) = \begin{cases} (1 + d_0 z^{-1}) \prod_{k=1}^{\frac{r-1}{2}} (1 + d_{k1} z^{-1} + d_{k2} z^{-2}), & \text{if } r \text{ odd} \\ \prod_{k=1}^{\frac{r}{2}} (1 + d_{k1} z^{-1} + d_{k2} z^{-2}), & \text{if } r \text{ even} \end{cases}$$

Define the two model filter coefficient vectors as

$$\mathbf{a} = [a_0 \ a_1 \ \dots \ a_n]^T$$

and

$$\begin{aligned} \mathbf{d} &= \begin{bmatrix} d_0 \\ d_1 \\ \vdots \\ d_L \end{bmatrix} \\ \mathbf{d}_k &= \begin{bmatrix} d_{k1} \\ d_{k2} \end{bmatrix}, \quad \text{for } 1 \leq k \leq L \\ L &= \begin{cases} \frac{r-1}{2}, & \text{if } r \text{ odd} \\ \frac{r}{2}, & \text{if } r \text{ even} \end{cases} \end{aligned}$$

The masking filters are

$$\begin{aligned} F_{M_a}(z) &= \sum_{k=0}^{n_a-1} p_k z^{-k} \\ F_{M_c}(z) &= \sum_{k=0}^{n_c-1} q_k z^{-k} \end{aligned}$$

$F_{M_a}(z)$ and $F_{M_c}(z)$ are assumed to have linear phase responses; the lengths n_a and n_c are assumed to be both even or odd; and the group delays of $F_{M_a}(z)$ and $F_{M_c}(z)$ are both $d = \max\left\{\frac{n_a-1}{2}, \frac{n_c-1}{2}\right\}$ (if necessary, one filter is padded with extra delays).

The frequency response of the symmetric, linear phase, FIR masking filters is (in the case of F_{M_a})

$$\begin{aligned} F_{M_a}(\omega) &= \sum_{k=0}^{n_a-1} p_k e^{-i\omega k} \\ &= e^{-i\omega \frac{n_a-1}{2}} \begin{cases} p_{\frac{n_a-1}{2}} + 2 \sum_{k=1}^{\frac{n_a-1}{2}} p_{k+\frac{n_a-1}{2}} \cos k\omega, & \text{if } n_a \text{ odd} \\ 2 \sum_{k=1}^{\frac{n_a}{2}} p_{k+\frac{n_a}{2}-1} \cos(k - \frac{1}{2})\omega, & \text{if } n_a \text{ even} \end{cases} \end{aligned}$$

The desired passband group delay of the FRM filter is $D_s = d + MD$ where D is the group delay of the model filter. The desired frequency response of the FRM filter can be expressed as

$$e^{-iD_s \omega} H(\mathbf{x}, \omega)$$

where

$$H(\mathbf{x}, \omega) = \tilde{H}_a(M\omega) [\mathbf{a}_a^T \mathbf{c}_a(\omega) - \mathbf{a}_c^T \mathbf{c}_c(\omega)] + \mathbf{a}_c^T \mathbf{c}_c(\omega)$$

$$\begin{aligned}
\tilde{H}_a(\omega) &= e^{jD\omega} \frac{a(\omega)}{d(\omega)} = \frac{\mathbf{a}^T \mathbf{v}(\omega)}{d(\omega)} \\
\mathbf{v}(\omega) &= \mathbf{c}(\omega) + j\mathbf{s}(\omega) \\
\mathbf{c}(\omega) &= [\cos D\omega \quad \dots \quad \cos(D-n)\omega]^T \\
\mathbf{s}(\omega) &= [\sin D\omega \quad \dots \quad \sin(D-n)\omega]^T \\
v_1(\omega) &= \cos \omega - j \sin \omega \\
\mathbf{v}_2(\omega) &= \begin{bmatrix} \cos \omega \\ \cos 2\omega \end{bmatrix} - j \begin{bmatrix} \sin \omega \\ \sin 2\omega \end{bmatrix}
\end{aligned}$$

and

$$\begin{aligned}
d(\omega) &= \begin{cases} [1 + d_0 v_1(\omega)] \prod_{k=1}^L [1 + \mathbf{d}_k^T \mathbf{v}_2(\omega)], & \text{if } r \text{ odd} \\ \prod_{k=1}^L [1 + \mathbf{d}_k^T \mathbf{v}_2(\omega)], & \text{if } r \text{ even} \end{cases} \\
\mathbf{a}_a &= \begin{cases} \begin{bmatrix} p_{\frac{n_a-1}{2}} & p_{\frac{n_a+1}{2}} & \dots & p_{n_a-1} \end{bmatrix}^T, & \text{if } n_a \text{ odd} \\ \begin{bmatrix} p_{\frac{n_a}{2}} & p_{\frac{n_a}{2}+1} & \dots & p_{n_a-1} \end{bmatrix}^T, & \text{if } n_a \text{ even} \end{cases} \\
\mathbf{c}_a(\omega) &= \begin{cases} \begin{bmatrix} 1 & 2 \cos \omega & \dots & 2 \cos \frac{(n_a-1)}{2} \omega \end{bmatrix}^T, & \text{if } n_a \text{ odd} \\ \begin{bmatrix} 2 \cos \frac{1}{2}\omega & \dots & 2 \cos \frac{(n_a-1)}{2} \omega \end{bmatrix}^T, & \text{if } n_a \text{ even} \end{cases} \\
\mathbf{a}_c &= \begin{cases} \begin{bmatrix} q_{\frac{n_c-1}{2}} & q_{\frac{n_c+1}{2}} & \dots & q_{n_c-1} \end{bmatrix}^T, & \text{if } n_c \text{ odd} \\ \begin{bmatrix} q_{\frac{n_c}{2}} & q_{\frac{n_c}{2}+1} & \dots & q_{n_c-1} \end{bmatrix}^T, & \text{if } n_c \text{ even} \end{cases} \\
\mathbf{c}_c(\omega) &= \begin{cases} \begin{bmatrix} 1 & 2 \cos \omega & \dots & 2 \cos \frac{(n_c-1)}{2} \omega \end{bmatrix}^T, & \text{if } n_c \text{ odd} \\ \begin{bmatrix} 2 \cos \frac{1}{2}\omega & \dots & 2 \cos \frac{(n_c-1)}{2} \omega \end{bmatrix}^T, & \text{if } n_c \text{ even} \end{cases}
\end{aligned}$$

The gradient of $H(\mathbf{x}, \omega)$ is

$$\frac{\partial H(\mathbf{x}, \omega)}{\partial \mathbf{x}} = \begin{bmatrix} y(\omega) \frac{\partial \tilde{H}_a(M\omega)}{\partial \mathbf{a}} \\ y(\omega) \frac{\partial \tilde{H}_a(M\omega)}{\partial \mathbf{d}} \\ \tilde{H}_a(M\omega) \mathbf{c}_a(\omega) \\ [1 - \tilde{H}_a(M\omega)] \mathbf{c}_c(\omega) \end{bmatrix}^T$$

where

$$\begin{aligned}
y(\omega) &= \mathbf{a}_a^T \mathbf{c}_a(\omega) - \mathbf{a}_c^T \mathbf{c}_c(\omega) \\
\frac{\partial \tilde{H}_a(\omega)}{\partial \mathbf{a}} &= \frac{\mathbf{v}(\omega)}{d(\omega)} \\
\frac{\partial \tilde{H}_a(\omega)}{\partial \mathbf{d}} &= \left[\frac{\partial \tilde{H}_a(\omega)}{\partial d_0} \quad \frac{\partial \tilde{H}_a(\omega)}{\partial d_1} \quad \dots \quad \frac{\partial \tilde{H}_a(\omega)}{\partial d_L} \right]
\end{aligned}$$

with

$$\begin{aligned}
\frac{\partial \tilde{H}_a(\omega)}{\partial d_0} &= -\tilde{H}_a(\omega) \frac{v_1(\omega)}{1 + d_0 v_1(\omega)} \\
\frac{\partial \tilde{H}_a(\omega)}{\partial d_k} &= -\tilde{H}_a(\omega) \frac{\mathbf{v}_2(\omega)}{1 + \mathbf{d}_k^T \mathbf{v}_2(\omega)}, \quad \text{for } 1 \leq k \leq L
\end{aligned}$$

The overall parameter vector is

$$\mathbf{x} = \begin{bmatrix} \mathbf{a} \\ \mathbf{d} \\ \mathbf{a}_a \\ \mathbf{a}_c \end{bmatrix}$$

The calculation of the FRM zero-phase frequency response, $H(\mathbf{x}, \omega)$, and its gradient with respect to the coefficients is implemented in the Octave function `frm2ndOrderCascade()`.

The SOCP optimisation of an FRM filter is implemented in the Octave function `frm2ndOrderCascade_socp()`. The Octave script `frm2ndOrderCascade_socp_test()` designs a FRM filter similar to that of the example shown by Lu and Hinamoto [160, Section V.E]. The specification of the FRM filter is:

```

tol=1e-06 % Tolerance on coefficient update vector
n=1200 % Frequency points across the band
mn=10 % Model filter numerator order (mn+1 coefficients)
mr=10 % Model filter denominator order (mr coefficients)
na=33 % Model masking filter FIR length
nc=33 % Model complementary masking filter FIR length
M=9 % Decimation
Dmodel=7 % Model filter pass band group delay
dmask=16 % Masking filter nominal delay
fpass= 0.3 % Pass band edge
fstop=0.305 % Stop band edge
dBas=55 % Stop band attenuation
Wap=1 % Pass band weight
Wapextra=0 % Extra weight for extra pass band points
Wasextra=0 % Extra weight for extra stop band points
Was=9 % Stop band weight
tau=0.1 % Stability parameter
edge_factor=0.1 % Add extra frequencies near band edges
edge_ramp=0 % Linear change in extra weights over edge region

```

For comparison, the example of Lu and Hinamoto uses $mn = 14$, $n_a = 41$ and $D = 9$ and has a nominal passband delay of 101 samples. The SOCP pass minimises the combined error of the pass and stop bands at the constraint frequencies. Those frequencies are chosen so that half are concentrated in the union of the regions $[0.9f_p \quad f_p]$ and $[f_s \quad 1.1f_s]$. I found during debugging that the best results were obtained if the model filter denominator polynomial second order sections are rearranged after each of the first few SOCP passes. The initial filter uses FIR filter and IIR model filter numerator polynomials calculated by the Octave *remez* function and a model filter denominator polynomial of $d = 1$. This initial FRM filter results in a better FRM filter than the initial FRM filter calculated by the Octave script *tarczynski_frm_iir_test.m*.

The model filter numerator polynomial is

```
a = [ -0.0665914944, 0.2071037076, -0.2566185237, 0.0450229040, ...

```

10.4.3 Design of an FRM digital filter with an IIR model filter represented in gain-pole-zero form using SOCP and PCLS optimisation

This section describes an FRM filter with the *Lim* FRM filter structure shown in Figure 10.77 in which the model filter is represented in gain-pole-zero form and the FIR masking filters are symmetric (ie: linear phase). The squared-amplitude and the group delay of the MMSE optimised FRM filter response are constrained by the PCLS algorithm of *Selesnick, Lang and Burrus*, described in Section 8.1.2.

Using the notation of Section 10.4.2, the desired passband group delay of the FRM filter is $D_s = d_{mask} + M_{model}D_{model}$, where D_{model} is the delay of the pure delay branch of the FRM filter, M_{model} is the decimation factor of the IIR model filter and d_{mask} is the group delay of the linear phase FIR masking filters. If $R(\omega) e^{i\phi_R(\omega)}$ is the frequency response of the IIR model filter then the *zero phase* response of the FRM filter is

$$H(x, \omega) = A(\omega) R(M\omega) e^{i\phi_Z(M\omega)} + B(\omega)$$

where

$$\begin{aligned}\phi_Z(\omega) &= D\omega + \phi_R(\omega) \\ A(\omega) &= \mathbf{a}_a^T \mathbf{c}_a(\omega) - \mathbf{a}_c^T \mathbf{c}_c(\omega) \\ B(\omega) &= \mathbf{a}_c^T \mathbf{c}_c(\omega)\end{aligned}$$

The squared-magnitude and phase responses of the zero phase response of the FRM filter are

$$\begin{aligned}|H(\omega)|^2 &= A^2(\omega) R^2(M\omega) + B^2(\omega) + 2A(\omega) B(\omega) R(M\omega) \cos \phi_Z(M\omega) \\ \phi_H(\omega) &= \arctan \frac{A(\omega) R(M\omega) \sin \phi_Z(M\omega)}{A(\omega) R(M\omega) \cos \phi_Z(M\omega) + B(\omega)}\end{aligned}$$

The group delay response, $T(\omega)$, of the zero phase response of the FRM filter (ie: the group delay error of the FRM filter, $-\frac{\partial \phi_H}{\partial \omega}$) is given by

$$\begin{aligned}|H(\omega)|^2 T(\omega) &= - (A^2(\omega) R^2(M\omega) + A(\omega) B(\omega) R(M\omega) \cos \phi_Z(M\omega)) \frac{\partial \phi_Z(M\omega)}{\partial \omega} \dots \\ &\quad - A(\omega) B(\omega) \sin \phi_Z(M\omega) \frac{\partial R(M\omega)}{\partial \omega} \dots \\ &\quad + R(M\omega) \sin \phi_Z(M\omega) \left(A(\omega) \frac{\partial B(\omega)}{\partial \omega} - B(\omega) \frac{\partial A(\omega)}{\partial \omega} \right)\end{aligned}$$

where

$$\begin{aligned}\frac{\partial \phi_Z(M\omega)}{\partial \omega} &= DM + \frac{\partial \phi_R(M\omega)}{\partial \omega} \\ \frac{\partial A(\omega)}{\partial \omega} &= \mathbf{a}_a^T \mathbf{s}_a(\omega) - \mathbf{a}_c^T \mathbf{s}_c(\omega) \\ \frac{\partial B(\omega)}{\partial \omega} &= \mathbf{a}_c^T \mathbf{s}_c(\omega) \\ \mathbf{s}_a(\omega) &= \begin{cases} -2 \left[\begin{array}{cccc} 0 & \sin \omega & \dots & \frac{(n_a-1)}{2} \sin \frac{(n_a-1)}{2} \omega \end{array} \right]^T, & \text{if } n_a \text{ odd} \\ -2 \left[\begin{array}{cccc} \sin \frac{1}{2} \omega & \dots & \frac{(n_a-1)}{2} \sin \frac{(n_a-1)}{2} \omega \end{array} \right]^T, & \text{if } n_a \text{ even} \end{cases} \\ \mathbf{s}_c(\omega) &= \begin{cases} -2 \left[\begin{array}{cccc} 0 & \sin \omega & \dots & \frac{(n_c-1)}{2} \sin \frac{(n_c-1)}{2} \omega \end{array} \right]^T, & \text{if } n_c \text{ odd} \\ -2 \left[\begin{array}{cccc} \sin \frac{1}{2} \omega & \dots & \frac{(n_c-1)}{2} \sin \frac{(n_c-1)}{2} \omega \end{array} \right]^T, & \text{if } n_c \text{ even} \end{cases}\end{aligned}$$

The gradients of $|H(\omega)|^2$ with respect to the coefficients are

$$\begin{aligned}\frac{\partial |H(\omega)|^2}{\partial \mathbf{r}} &= 2 (A^2(\omega) R(M\omega) + A(\omega) B(\omega) \cos \phi_Z(M\omega)) \frac{\partial R(M\omega)}{\partial \mathbf{r}} \dots \\ &\quad - 2A(\omega) B(\omega) R(M\omega) \sin \phi_Z(M\omega) \frac{\partial \phi_R(M\omega)}{\partial \mathbf{r}} \\ \frac{\partial |H(\omega)|^2}{\partial \mathbf{a}} &= 2 (A(\omega) R^2(M\omega) + B(\omega) R(M\omega) \cos \phi_Z(M\omega)) \frac{\partial A(\omega)}{\partial \mathbf{a}} \dots\end{aligned}$$

$$+ 2(B(\omega) + A(\omega)R(M\omega)\cos\phi_Z(M\omega)) \frac{\partial B(\omega)}{\partial \mathbf{a}}$$

where \mathbf{r} represents the coefficients of the IIR model filter, and \mathbf{a} represents the coefficients of both the masking filter, \mathbf{a}_a , and the complementary masking filter, \mathbf{a}_c .

The gradients of $T(\omega)$ with respect to the coefficients are given by

$$\begin{aligned} \frac{\partial |H(\omega)|^2}{\partial \mathbf{r}} T(\omega) + |H(\omega)|^2 \frac{\partial T(\omega)}{\partial \mathbf{r}} &= \dots \\ - (A^2(\omega)R^2(M\omega) + A(\omega)B(\omega)R(M\omega)\cos\phi_Z(M\omega)) \frac{\partial^2 \phi_R(M\omega)}{\partial \omega \partial \mathbf{r}} \dots \\ - (2A^2(\omega)R(M\omega) + A(\omega)B(\omega)\cos\phi_Z(M\omega)) \frac{\partial \phi_Z(M\omega)}{\partial \omega} \frac{\partial R(M\omega)}{\partial \mathbf{r}} \dots \\ + A(\omega)B(\omega)R(M\omega)\sin\phi_Z(M\omega) \frac{\partial \phi_Z(M\omega)}{\partial \omega} \frac{\partial \phi_R(M\omega)}{\partial \mathbf{r}} \dots \\ - A(\omega)B(\omega)\cos\phi_Z(M\omega) \frac{\partial R(M\omega)}{\partial \omega} \frac{\partial \phi_R(M\omega)}{\partial \mathbf{r}} \dots \\ - A(\omega)B(\omega)\sin\phi_Z(M\omega) \frac{\partial^2 R(M\omega)}{\partial \omega \partial \mathbf{r}} \dots \\ + \sin\phi_Z(M\omega) \frac{\partial R(M\omega)}{\partial \mathbf{r}} \left(A(\omega) \frac{\partial B(\omega)}{\partial \omega} - B(\omega) \frac{\partial A(\omega)}{\partial \omega} \right) \dots \\ + R(M\omega)\cos\phi_Z(M\omega) \frac{\partial \phi_R(M\omega)}{\partial \mathbf{r}} \left(A(\omega) \frac{\partial B(\omega)}{\partial \omega} - B(\omega) \frac{\partial A(\omega)}{\partial \omega} \right) \end{aligned}$$

and

$$\begin{aligned} \frac{\partial |H(\omega)|^2}{\partial \mathbf{a}} T(\omega) + |H(\omega)|^2 \frac{\partial T(\omega)}{\partial \mathbf{a}} &= \dots \\ - (2A(\omega)R^2(M\omega) + B(\omega)R(M\omega)\cos\phi_Z(M\omega)) \frac{\partial \phi_Z(M\omega)}{\partial \omega} \frac{\partial A(\omega)}{\partial \mathbf{a}} \dots \\ - A(\omega)R(M\omega)\cos\phi_Z(M\omega) \frac{\partial \phi_Z(M\omega)}{\partial \omega} \frac{\partial B(\omega)}{\partial \mathbf{a}} \dots \\ - \sin\phi_Z(M\omega) \frac{\partial R(M\omega)}{\partial \omega} \left(A(\omega) \frac{\partial B(\omega)}{\partial \mathbf{a}} + B(\omega) \frac{\partial A(\omega)}{\partial \mathbf{a}} \right) \dots \\ - R(M\omega)\sin\phi_Z(M\omega) \left(\frac{\partial A(\omega)}{\partial \omega} \frac{\partial B(\omega)}{\partial \mathbf{a}} - \frac{\partial B(\omega)}{\partial \omega} \frac{\partial A(\omega)}{\partial \mathbf{a}} \right) \dots \\ + R(M\omega)\sin\phi_Z(M\omega) \left(A(\omega) \frac{\partial^2 B(\omega)}{\partial \omega \partial \mathbf{a}} - B(\omega) \frac{\partial^2 A(\omega)}{\partial \omega \partial \mathbf{a}} \right) \end{aligned}$$

The amplitude, phase and group delay responses and gradients of the IIR model filter are calculated by the Octave functions *iirA*, *iirP* and *iirT*. The derivative with respect to frequency of the IIR model filter amplitude response, $\frac{\partial R}{\partial \omega}$, is derived in Appendix F and calculated by the Octave function *iirdelAdelw*. The Octave function *iir_frm.m* returns the low pass FRM filter squared-magnitude and group delay error responses and their gradients.

The Octave function *iir_frm_socp_mmse.m* finds the SOCP solution that optimises the coefficients of a filter response calculated by *iir_frm.m* with the required linear amplitude and group delay constraints. To avoid numerical problems, *iir_frm_socp_mmse.m* sets the *SeDuMi* parameter *pars.eps* to $1e-6$ rather than the default $1e-8$. The Octave function *iir_frm_slb.m* implements the PCLS algorithm for finding the constraint frequencies. The Octave script *iir_frm_socp_slb_test.m* designs an FRM filter with the following specification:

```
n=800 % Frequency points across the band
tol=0.001 % Tolerance on relative coefficient update size
ctol=5e-06 % Tolerance on constraints
ma=10 % IIR model filter numerator order
md=10 % IIR model filter denominator order
na=41 % FIR masking filter length (order+1)
nc=41 % FIR complementary masking filter length (order+1)
Mmodel=9 % Model filter decimation factor
Dmodel=7 % Model filter nominal pass band group delay
dmask=20 % FIR masking filter delay
Tnominal=83 % FIR masking filter delay
fap=0.3 % Pass band edge
dBap=0.2 % Pass band amplitude peak-to-peak ripple
```

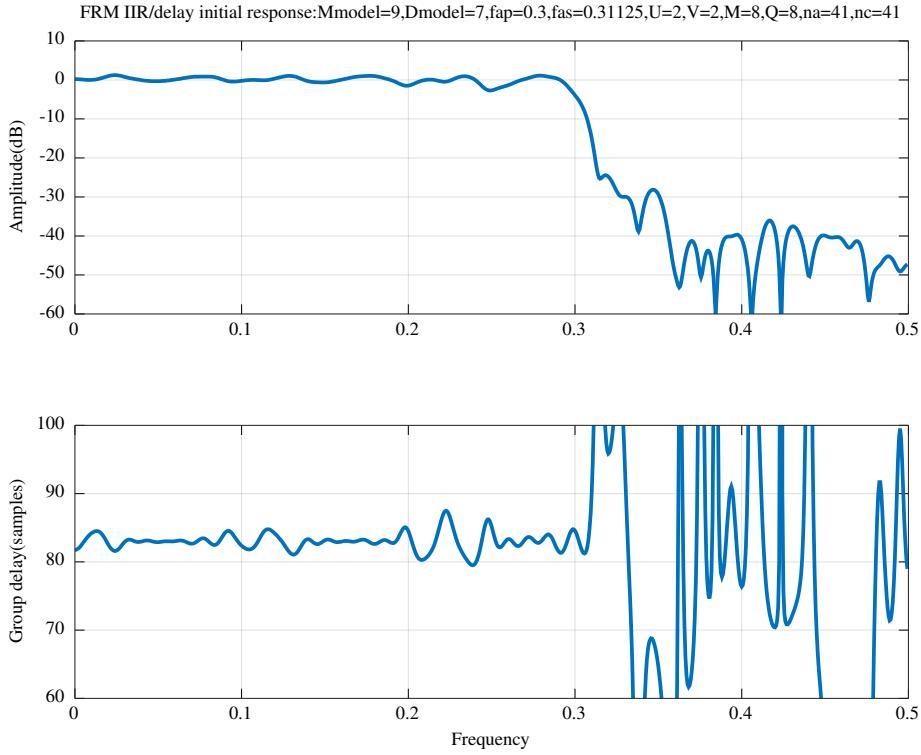

Figure 10.85: FRM gain-pole-zero format IIR model filter with WISE optimisation : initial response

```

Wap=1 % Pass band weight
tpr=1 % Pass band delay peak-to-peak ripple
Wtp=0.01 % Pass band delay weight
Wat=1e-06 % Transition band amplitude weight
fas=0.31125 % Stop band edge
dBas=45 % Stop band attenuation ripple
fasA=0.31125 % Additional stop band edge
dBAsA=45 % Additional stop band attenuation ripple
Was=100 % Stop band weight

```

The passband edge frequency is the same as that of the design example given by Lu and Hinamoto [160, Section V.E], namely 0.300, but the stop band edge frequency is relaxed from 0.305 to 0.31125. Both FIR masking filters have length 41. The initial filter is designed by the Octave script *tarczynski_frm_iir_test.m* with the WISE method of Tarczynski *et al.* (as shown in Section 8.1.5). Figure 10.85 shows the overall response of the initial FRM filter. After SOCP and PCLS optimisation of the initial response the resulting IIR model filter numerator polynomial is

```
a = [ 0.0013190730, 0.0010277579, -0.0023251495, -0.0032208776, ...

10.4.4 Design of an FRM digital filter with an allpass model filter represented in gain-pole-zero form using SOCP and PCLS optimisation

This section describes an FRM filter with the structure shown in Figure 10.78, and an all-pass filter. For simplicity the model filters consist of an allpass filter in parallel with a pure delay and the FIR masking filters are of equal odd length and are symmetric (ie: the FIR masking filters are even order and linear phase). The squared-amplitude and the group delay of the MMSE optimised FRM filter response are constrained by the PCLS algorithm of *Selesnick, Lang and Burrus*, described in Section 8.1.2.

Using the notation of Section 10.4.2, the desired passband group delay of the FRM filter is $D_s = d + MD$, where D is the group delay of the model filter, M is the decimation factor of the model filter and d is the group delay of the linear phase FIR masking filters. The *zero phase* response of the FRM filter is

$$H(\mathbf{x}, \omega) = e^{i[D M \omega + \phi_R(M\omega)]} A(\omega) + B(\omega)$$

where $\phi_R(\omega)$ is the phase response of the allpass branch of the model filter and:

$$\begin{aligned} A(\omega) &= \frac{\mathbf{a}_a^T \mathbf{c}_a(\omega) + \mathbf{a}_c^T \mathbf{c}_c(\omega)}{2} \\ B(\omega) &= \frac{\mathbf{a}_a^T \mathbf{c}_a(\omega) - \mathbf{a}_c^T \mathbf{c}_c(\omega)}{2} \end{aligned}$$

The squared-magnitude and phase responses of the zero phase response of the FRM filter are:

$$\begin{aligned} |H(\omega)|^2 &= A^2(\omega) + B^2(\omega) + 2A(\omega)B(\omega)\cos\phi_Z(M\omega) \\ \phi_H(\omega) &= \arctan \frac{A(\omega)\sin\phi_Z(M\omega)}{A(\omega)\cos\phi_Z(M\omega) + B(\omega)} \end{aligned}$$

where $\phi_Z(\omega) = D\omega + \phi_R(\omega)$.

The group delay response, $T(\omega)$, of the zero phase response of the FRM filter (ie: the group delay error of the FRM filter) is given by:

$$\begin{aligned} |H(\omega)|^2 T(\omega) &= - (A^2(\omega) + A(\omega)B(\omega)\cos\phi_Z(M\omega)) \frac{\partial\phi_Z(M\omega)}{\partial\omega} \dots \\ &\quad - B(\omega)\sin\phi_Z(M\omega) \frac{\partial A(\omega)}{\partial\omega} \dots \\ &\quad + A(\omega)\sin\phi_Z(M\omega) \frac{\partial B(\omega)}{\partial\omega} \end{aligned}$$

where:

$$\begin{aligned} \frac{\partial\phi_Z(M\omega)}{\partial\omega} &= DM + \frac{\partial\phi_R(M\omega)}{\partial\omega} \\ \frac{\partial A(\omega)}{\partial\omega} &= \frac{\mathbf{a}_a^T \mathbf{s}_a(\omega) + \mathbf{a}_c^T \mathbf{s}_c(\omega)}{2} \\ \frac{\partial B(\omega)}{\partial\omega} &= \frac{\mathbf{a}_a^T \mathbf{s}_a(\omega) - \mathbf{a}_c^T \mathbf{s}_c(\omega)}{2} \\ \mathbf{s}_a(\omega) &= -2 \left[\begin{array}{cccc} 0 & \sin\omega & \dots & \frac{(n_a-1)}{2} \sin \frac{(n_a-1)}{2}\omega \end{array} \right]^T \\ \mathbf{s}_c(\omega) &= -2 \left[\begin{array}{cccc} 0 & \sin\omega & \dots & \frac{(n_c-1)}{2} \sin \frac{(n_c-1)}{2}\omega \end{array} \right]^T \end{aligned}$$

The gradients of $|H(\omega)|^2$ with respect to the coefficients are:

$$\begin{aligned} \frac{\partial|H(\omega)|^2}{\partial\mathbf{r}} &= -2A(\omega)B(\omega)\sin\phi_Z(M\omega) \frac{\partial\phi_R(M\omega)}{\partial\mathbf{r}} \\ \frac{\partial|H(\omega)|^2}{\partial\mathbf{a}} &= 2(A(\omega) + B(\omega)\cos\phi_Z(M\omega)) \frac{\partial A(\omega)}{\partial\mathbf{a}} + 2(B(\omega) + A(\omega)\cos\phi_Z(M\omega)) \frac{\partial B(\omega)}{\partial\mathbf{a}} \end{aligned}$$

where \mathbf{r} represents the coefficients of the allpass model filter, and \mathbf{a} represents the coefficients of both the masking filter, \mathbf{a}_a , and the complementary masking filter, \mathbf{a}_c .

The gradients of $\phi_H(\omega)$ with respect to the coefficients are:

$$|H(\omega)|^2 \frac{\partial\phi_H(\omega)}{\partial\mathbf{r}} = A(\omega)[A(\omega) + B(\omega)\cos\phi_Z(M\omega)] \frac{\partial\phi_R(M\omega)}{\partial\mathbf{r}}$$

$$|H(\omega)|^2 \frac{\partial \phi_H(\omega)}{\partial \mathbf{a}} = \sin \phi_Z(M\omega) \left[B(\omega) \frac{\partial A(\omega)}{\partial \mathbf{a}} - A(\omega) \frac{\partial B(\omega)}{\partial \mathbf{a}} \right]$$

The gradients of $T(\omega)$ with respect to the coefficients are given by:

$$\begin{aligned} \frac{\partial |H(\omega)|^2}{\partial \mathbf{r}} T(\omega) + |H(\omega)|^2 \frac{\partial T(\omega)}{\partial \mathbf{r}} &= - (A^2(\omega) + A(\omega)B(\omega) \cos \phi_Z(M\omega)) \frac{\partial^2 \phi_Z(M\omega)}{\partial \mathbf{r} \partial \omega} \dots \\ &\quad + A(\omega)B(\omega) \sin \phi_Z(M\omega) \frac{\partial \phi_R(M\omega)}{\partial \mathbf{r}} \frac{\partial \phi_Z(M\omega)}{\partial \omega} \dots \\ &\quad + A(\omega) \cos \phi_Z(M\omega) \frac{\partial \phi_R(M\omega)}{\partial \mathbf{r}} \frac{\partial B(\omega)}{\partial \omega} \dots \\ &\quad - B(\omega) \cos \phi_Z(M\omega) \frac{\partial \phi_R(M\omega)}{\partial \mathbf{r}} \frac{\partial A(\omega)}{\partial \omega} \dots \\ \frac{\partial |H(\omega)|^2}{\partial \mathbf{a}} T(\omega) + |H(\omega)|^2 \frac{\partial T(\omega)}{\partial \mathbf{a}} &= - (2A(\omega) + B(\omega) \cos \phi_Z(M\omega)) \frac{\partial A(\omega)}{\partial \mathbf{a}} \frac{\partial \phi_Z(M\omega)}{\partial \omega} \dots \\ &\quad - A(\omega) \cos \phi_Z(M\omega) \frac{\partial B(\omega)}{\partial \mathbf{a}} \frac{\partial \phi_Z(M\omega)}{\partial \omega} \dots \\ &\quad + \sin \phi_Z(M\omega) \frac{\partial A(\omega)}{\partial \mathbf{a}} \frac{\partial B(\omega)}{\partial \omega} - \sin \phi_Z(M\omega) \frac{\partial B(\omega)}{\partial \mathbf{a}} \frac{\partial A(\omega)}{\partial \omega} \dots \\ &\quad + A(\omega) \sin \phi_Z(M\omega) \frac{\partial^2 B(\omega)}{\partial \mathbf{a} \partial \omega} - B(\omega) \sin \phi_Z(M\omega) \frac{\partial^2 A(\omega)}{\partial \mathbf{a} \partial \omega} \end{aligned}$$

The values and gradients of $\phi_R(\omega)$ are calculated by the Octave *allpassP* and *allpassT* functions.

The Octave function *iir_frm_allpass.m* returns the low pass FRM filter squared-magnitude and group delay error responses and their gradients. It is exercised by the Octave script *iir_frm_allpass_test.m*. The Octave function *iir_frm_allpass_socp_mmse* finds the SOCP solution that optimises the coefficients of a filter response calculated by *iir_frm_allpass* with the required amplitude and group delay constraints. The Octave function *iir_frm_allpass_slb* implements the PCLS algorithm for finding the constraint frequencies.

The Octave script *iir_frm_allpass_socp_slb_test.m* designs an FRM filter with the following specification:

```
tol=2e-05 % Tolerance on coefficient update vector
ctol=2e-05 % Tolerance on constraints
n=1000 % Frequency points across the band
mr=10 % Allpass model filter denominator order
R=1 % Allpass model filter decimation factor
na=41 % FIR masking filter length (order+1)
nc=41 % FIR complementary masking filter length (order+1)
Mmodel=9 % Model filter decimation factor
Dmodel=9 % Model filter nominal pass band group delay
dmask=20 % FIR masking filter delay
Tnominal=101 % Nominal FRM filter group delay
fap=0.3 % Pass band edge
dBap=0.05 % Pass band amplitude peak-to-peak ripple
Wap=1 % Pass band weight
tpr=1 % Pass band delay peak-to-peak ripple
Wtp=0.02 % Pass band delay weight
fas=0.3105 % Stop band edge
dBas=40 % Stop band attenuation ripple
Was=100 % Stop band weight
rho=0.968750 % Constraint on allpass pole radius
```

The passband edge frequency is the same as for the design example given by Lu and Hinamoto [160, Section V.E], namely 0.300, but the stop band edge frequency is relaxed slightly from 0.305 to 0.31. Both FIR masking filters have length 41. The initial filter is designed by the Octave script *tarczynski_frm_allpass_test.m* with the WISE method of *Tarczynski et al.* as shown in Section 8.1.5. Figure 10.90 shows the overall response of the initial FRM filter. After SOCP and PCLS optimisation of the initial filter the resulting model filter allpass filter denominator polynomial is

```

10.4.5 Design of an FRM digital filter with an IIR model filter consisting of parallel allpass filters

Figure 10.78 shows an FRM filter with a model filter consisting of parallel allpass filters. The filter transfer function is

$$H(z) = \frac{1}{2} [R(z^M) + S(z^M)] F_{M_a}(z) + \frac{1}{2} [R(z^M) - S(z^M)] F_{M_c}(z)$$

where $R(z)$ and $S(z)$ are allpass filters and, as previously, $F_{M_a}(z)$ and $F_{M_c}(z)$ are the masking and complementary masking filters

$$F_{M_a}(z) = \sum_{k=0}^{n_a-1} p_k z^{-k}$$

$$F_{M_c}(z) = \sum_{k=0}^{n_c-1} q_k z^{-k}$$

An equivalent filter is

$$H(z) = R(z^M) A(z) + S(z^M) B(z)$$

where

$$A(z) = \frac{1}{2} [F_{M_a}(z) + F_{M_c}(z)] = \sum_{k=0}^{n_m-1} a_k z^{-k}$$

$$B(z) = \frac{1}{2} [F_{M_a}(z) - F_{M_c}(z)] = \sum_{k=0}^{n_m-1} b_k z^{-k}$$

n_m is the larger of n_a and n_c and the a_k or b_k are zero-padded as required. If $\phi_R(\omega)$ and $\phi_S(\omega)$ are the phase responses of the allpass filters $R(z)$ and $S(z)$, then

$$H(\omega) = e^{i\phi_R(M\omega)} \sum_{k=0}^{n_m-1} a_k e^{-ik\omega} + e^{i\phi_S(M\omega)} \sum_{k=0}^{n_m-1} b_k e^{-ik\omega}$$

$$= \mathbf{c}_R \mathbf{a} + \mathbf{c}_S \mathbf{b} - i(\mathbf{s}_R \mathbf{a} + \mathbf{s}_S \mathbf{b})$$

where

$$\mathbf{a} = [a_0 \dots a_{n_m-1}]^T$$

$$\mathbf{b} = [b_0 \dots b_{n_m-1}]^T$$

$$\mathbf{v} = [0 \dots n_m - 1]$$

$$\mathbf{c}_R = \cos[\mathbf{v}\omega - \phi_R(M\omega)]$$

$$\mathbf{c}_S = \cos[\mathbf{v}\omega - \phi_S(M\omega)]$$

$$\mathbf{s}_R = \sin[\mathbf{v}\omega - \phi_R(M\omega)]$$

$$\mathbf{s}_S = \sin[\mathbf{v}\omega - \phi_S(M\omega)]$$

The squared-amplitude and phase responses of $H(z)$ are

$$|H(\omega)|^2 = (\mathbf{c}_R \mathbf{a} + \mathbf{c}_S \mathbf{b})^2 + (\mathbf{s}_R \mathbf{a} + \mathbf{s}_S \mathbf{b})^2$$

$$\phi_H(\omega) = -\arctan \frac{\mathbf{s}_R \mathbf{a} + \mathbf{s}_S \mathbf{b}}{\mathbf{c}_R \mathbf{a} + \mathbf{c}_S \mathbf{b}}$$

The group delay response is given by

$$|H(\omega)|^2 T(\omega) = (\mathbf{c}_R \mathbf{a} + \mathbf{c}_S \mathbf{b}) \left(\frac{\partial \mathbf{s}_R}{\partial \omega} \mathbf{a} + \frac{\partial \mathbf{s}_S}{\partial \omega} \mathbf{b} \right) - (\mathbf{s}_R \mathbf{a} + \mathbf{s}_S \mathbf{b}) \left(\frac{\partial \mathbf{c}_R}{\partial \omega} \mathbf{a} + \frac{\partial \mathbf{c}_S}{\partial \omega} \mathbf{b} \right)$$

where

$$\frac{\partial \mathbf{c}_R}{\partial \omega} = - \left[\mathbf{v} - \frac{\partial \phi_R(M\omega)}{\partial \omega} \right] \circ \mathbf{s}_R$$

$$\begin{aligned}\frac{\partial \mathbf{c}_S}{\partial \omega} &= - \left[\mathbf{v} - \frac{\partial \phi_S(M\omega)}{\partial \omega} \right] \circ \mathbf{s}_S \\ \frac{\partial \mathbf{s}_R}{\partial \omega} &= \left[\mathbf{v} - \frac{\partial \phi_R(M\omega)}{\partial \omega} \right] \circ \mathbf{c}_R \\ \frac{\partial \mathbf{s}_S}{\partial \omega} &= \left[\mathbf{v} - \frac{\partial \phi_S(M\omega)}{\partial \omega} \right] \circ \mathbf{c}_S\end{aligned}$$

The \circ symbol represents the *Hadamard* or element-wise product.

The gradients of the squared amplitude response are

$$\begin{aligned}\frac{\partial |H(\omega)|^2}{\partial \mathbf{r}} &= 2(\mathbf{c}_R \mathbf{a} + \mathbf{c}_S \mathbf{b}) \frac{\partial \mathbf{c}_R}{\partial \mathbf{r}} \mathbf{a} + 2(\mathbf{s}_R \mathbf{a} + \mathbf{s}_S \mathbf{b}) \frac{\partial \mathbf{s}_R}{\partial \mathbf{r}} \mathbf{a} \\ &= 2((\mathbf{c}_S \mathbf{b})(\mathbf{s}_R \mathbf{a}) - (\mathbf{s}_S \mathbf{b})(\mathbf{c}_R \mathbf{a})) \frac{\partial \phi_R(M\omega)}{\partial \mathbf{r}} \\ \frac{\partial |H(\omega)|^2}{\partial \mathbf{s}} &= 2(\mathbf{c}_R \mathbf{a} + \mathbf{c}_S \mathbf{b}) \frac{\partial \mathbf{c}_S}{\partial \mathbf{s}} \mathbf{b} + 2(\mathbf{s}_R \mathbf{a} + \mathbf{s}_S \mathbf{b}) \frac{\partial \mathbf{s}_S}{\partial \mathbf{s}} \mathbf{b} \\ &= -2((\mathbf{c}_S \mathbf{b})(\mathbf{s}_R \mathbf{a}) - (\mathbf{s}_S \mathbf{b})(\mathbf{c}_R \mathbf{a})) \frac{\partial \phi_S(M\omega)}{\partial \mathbf{s}} \\ \frac{\partial |H(\omega)|^2}{\partial \mathbf{a}} &= 2(\mathbf{c}_R \mathbf{a} + \mathbf{c}_S \mathbf{b}) \mathbf{c}_R + 2(\mathbf{s}_R \mathbf{a} + \mathbf{s}_S \mathbf{b}) \mathbf{s}_R \\ \frac{\partial |H(\omega)|^2}{\partial \mathbf{b}} &= 2(\mathbf{c}_R \mathbf{a} + \mathbf{c}_S \mathbf{b}) \mathbf{c}_S + 2(\mathbf{s}_R \mathbf{a} + \mathbf{s}_S \mathbf{b}) \mathbf{s}_S\end{aligned}$$

The gradients of the group delay response are given by

$$\begin{aligned}\frac{\partial |H(\omega)|^2}{\partial \mathbf{r}} T(\omega) + |H(\omega)|^2 \frac{\partial T(\omega)}{\partial \mathbf{r}} &= \mathbf{s}_R \mathbf{a} \left(\frac{\partial \mathbf{s}_R}{\partial \omega} \mathbf{a} + \frac{\partial \mathbf{s}_S}{\partial \omega} \mathbf{b} \right) \frac{\partial \phi_R(M\omega)}{\partial \mathbf{r}} + (\mathbf{c}_R \mathbf{a} + \mathbf{c}_S \mathbf{b}) \frac{\partial^2 \mathbf{s}_R}{\partial \mathbf{r} \partial \omega} \mathbf{a} \\ &\quad + \mathbf{c}_R \mathbf{a} \left(\frac{\partial \mathbf{c}_R}{\partial \omega} \mathbf{a} + \frac{\partial \mathbf{c}_S}{\partial \omega} \mathbf{b} \right) \frac{\partial \phi_R(M\omega)}{\partial \mathbf{r}} - (\mathbf{s}_R \mathbf{a} + \mathbf{s}_S \mathbf{b}) \frac{\partial^2 \mathbf{c}_R}{\partial \mathbf{r} \partial \omega} \mathbf{a} \\ \frac{\partial |H(\omega)|^2}{\partial \mathbf{s}} T(\omega) + |H(\omega)|^2 \frac{\partial T(\omega)}{\partial \mathbf{s}} &= \mathbf{s}_S \mathbf{b} \left(\frac{\partial \mathbf{s}_R}{\partial \omega} \mathbf{a} + \frac{\partial \mathbf{s}_S}{\partial \omega} \mathbf{b} \right) \frac{\partial \phi_S(M\omega)}{\partial \mathbf{s}} + (\mathbf{c}_R \mathbf{a} + \mathbf{c}_S \mathbf{b}) \frac{\partial^2 \mathbf{s}_S}{\partial \mathbf{s} \partial \omega} \mathbf{b} \\ &\quad + \mathbf{c}_S \mathbf{b} \left(\frac{\partial \mathbf{c}_R}{\partial \omega} \mathbf{a} + \frac{\partial \mathbf{c}_S}{\partial \omega} \mathbf{b} \right) \frac{\partial \phi_S(M\omega)}{\partial \mathbf{s}} - (\mathbf{s}_R \mathbf{a} + \mathbf{s}_S \mathbf{b}) \frac{\partial^2 \mathbf{c}_S}{\partial \mathbf{s} \partial \omega} \mathbf{b} \\ \frac{\partial |H(\omega)|^2}{\partial \mathbf{a}} T(\omega) + |H(\omega)|^2 \frac{\partial T(\omega)}{\partial \mathbf{a}} &= \left(\frac{\partial \mathbf{s}_R}{\partial \omega} \mathbf{a} + \frac{\partial \mathbf{s}_S}{\partial \omega} \mathbf{b} \right) \mathbf{c}_R + (\mathbf{c}_R \mathbf{a} + \mathbf{c}_S \mathbf{b}) \frac{\partial \mathbf{s}_R}{\partial \omega} \\ &\quad - \left(\frac{\partial \mathbf{c}_R}{\partial \omega} \mathbf{a} + \frac{\partial \mathbf{c}_S}{\partial \omega} \mathbf{b} \right) \mathbf{s}_R - (\mathbf{s}_R \mathbf{a} + \mathbf{s}_S \mathbf{b}) \frac{\partial \mathbf{c}_R}{\partial \omega} \\ \frac{\partial |H(\omega)|^2}{\partial \mathbf{b}} T(\omega) + |H(\omega)|^2 \frac{\partial T(\omega)}{\partial \mathbf{b}} &= \left(\frac{\partial \mathbf{s}_R}{\partial \omega} \mathbf{a} + \frac{\partial \mathbf{s}_S}{\partial \omega} \mathbf{b} \right) \mathbf{c}_S + (\mathbf{c}_R \mathbf{a} + \mathbf{c}_S \mathbf{b}) \frac{\partial \mathbf{s}_S}{\partial \omega} \\ &\quad - \left(\frac{\partial \mathbf{c}_R}{\partial \omega} \mathbf{a} + \frac{\partial \mathbf{c}_S}{\partial \omega} \mathbf{b} \right) \mathbf{s}_S - (\mathbf{s}_R \mathbf{a} + \mathbf{s}_S \mathbf{b}) \frac{\partial \mathbf{c}_S}{\partial \omega}\end{aligned}$$

where

$$\begin{aligned}\frac{\partial^2 \mathbf{c}_R}{\partial \mathbf{r} \partial \omega} \mathbf{a} &= (\mathbf{s}_R \mathbf{a}) \frac{\partial^2 \phi_R(M\omega)}{\partial \mathbf{r} \partial \omega} + \left(\frac{\partial \mathbf{s}_R}{\partial \omega} \mathbf{a} \right) \frac{\partial \phi_R(M\omega)}{\partial \mathbf{r}} \\ \frac{\partial^2 \mathbf{c}_S}{\partial \mathbf{s} \partial \omega} \mathbf{b} &= (\mathbf{s}_S \mathbf{b}) \frac{\partial^2 \phi_S(M\omega)}{\partial \mathbf{s} \partial \omega} + \left(\frac{\partial \mathbf{s}_S}{\partial \omega} \mathbf{b} \right) \frac{\partial \phi_S(M\omega)}{\partial \mathbf{s}} \\ \frac{\partial^2 \mathbf{s}_R}{\partial \mathbf{r} \partial \omega} \mathbf{a} &= -(\mathbf{c}_R \mathbf{a}) \frac{\partial^2 \phi_R(M\omega)}{\partial \mathbf{r} \partial \omega} - \left(\frac{\partial \mathbf{c}_R}{\partial \omega} \mathbf{a} \right) \frac{\partial \phi_R(M\omega)}{\partial \mathbf{r}} \\ \frac{\partial^2 \mathbf{s}_S}{\partial \mathbf{s} \partial \omega} \mathbf{b} &= -(\mathbf{c}_S \mathbf{b}) \frac{\partial^2 \phi_S(M\omega)}{\partial \mathbf{s} \partial \omega} - \left(\frac{\partial \mathbf{c}_S}{\partial \omega} \mathbf{b} \right) \frac{\partial \phi_S(M\omega)}{\partial \mathbf{s}}\end{aligned}$$

The calculation of the filter response and gradients is implemented in the Octave function *iir_frm_parallel_allpass.m* which is exercised by the Octave script *iir_frm_parallel_allpass_test.m*.

The Octave script *iir_frm_parallel_allpass_socp_slb_test.m* designs an FRM filter with the following specification:

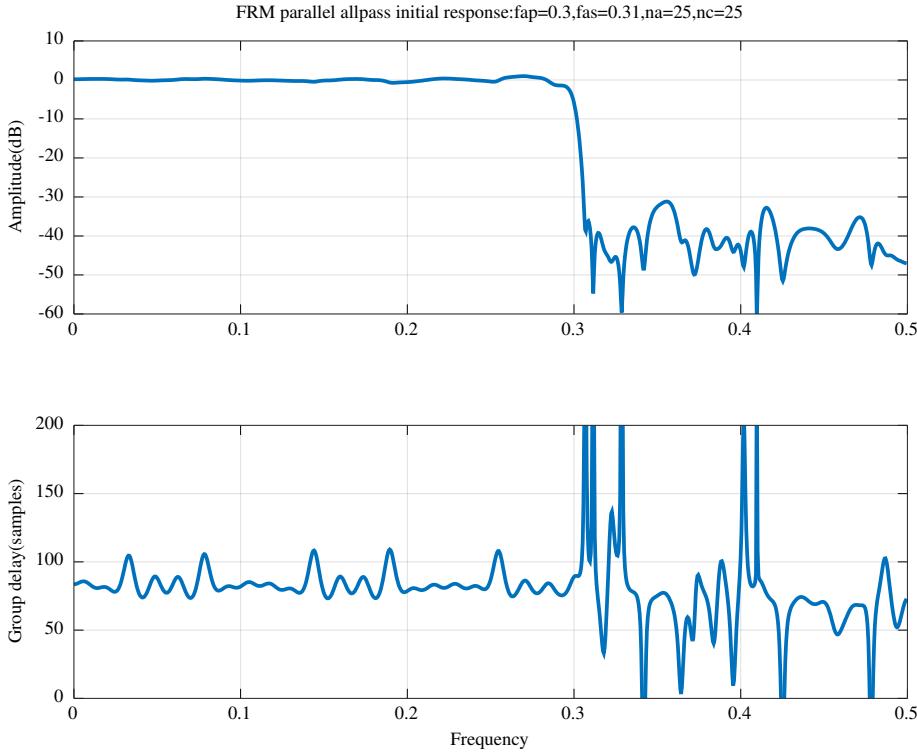

Figure 10.95: FRM filter with gain-pole-zero format parallel allpass model filter : initial response with WISE optimisation

```

tol=0.001 % Tolerance on coefficient update vector
ctol=2.5e-05 % Tolerance on constraints

```

In this example the FIR masking filters are not required to be linear phase and there is no constraint on the group delay of the filter. The Octave script *iir_frm_parallel_allpass_socp_slb_test.m* calls the Octave function *iir_frm_parallel_allpass_socp_mmse* to minimise the response error and the coefficient step size with the SeDuMi SOCP solver. The initial filter was calculated by the Octave script *tarczynski_frm_parallel_allpass_test.m* with the WISE method of Tarczynski et al. (see Section 8.1.5). The response of the initial filter is shown in Figure 10.95. The initial filter was SOCP and PCLS optimised with the Octave function *iir_frm_parallel_allpass_slb*. The resulting model filter parallel allpass filter denominator polynomials are

```
r = [ 1.0000000000, -0.5718781413, 0.7955435653, -0.4498307353, ...

10.4.6 Design of an FRM low-pass digital filter with an all-pass Schur lattice model filter in parallel with a delay using SOCP and PCLS optimisation

This section describes a low-pass FRM filter with the *Johansson* and *Wanhammar* FRM filter structure shown in Figure 10.78 in which the model filter is an all-pass Schur one-multiplier lattice filter in parallel with a delay and the FIR masking filters are symmetric (ie: linear phase) and even order. The squared-magnitude, phase and the group delay of the MMSE optimised FRM filter response are constrained by the PCLS algorithm of *Selesnick, Lang and Burrus*, described in Section 8.1.2. The calculations for this filter are similar to those in Section 10.4.4 with the values and gradients of $\phi_R(\omega)$ calculated by the Octave *schurOneMAPlatticeP.m* and *schurOneMAPlatticeT.m* functions. The Octave function *schurOneMAPlattice_frmEsq.m* returns the FRM filter squared-magnitude, phase and group delay error responses and their gradients. The Octave function *schurOneMAPlattice_frm_socp_mmse* finds the SOCP solution that optimises the coefficients of a filter error response calculated by *schurOneMAPlattice_frmEsq* with the required amplitude, phase and group delay constraints. The Octave function *schurOneMAPlattice_frm_slb* implements the PCLS algorithm for finding the constraint frequencies. The Octave script *schurOneMAPlattice_frm_socp_slb_test.m* designs an FRM filter with the following specification:

```
n=1000 % Frequency points
tol=0.0001 % Tolerance on coefficient update vector
ctol=1e-05 % Tolerance on constraints
Mmodel=9 % Model filter decimation
Dmodel=9 % Desired model filter passband delay
dmask=20 % FIR masking filter delay
fap=0.3 % Amplitude pass band edge
dBap=0.05 % Pass band amplitude ripple
Wap=1 % Pass band amplitude weight
fas=0.3105 % Amplitude stop band edge
dBas=43 % Stop band amplitude ripple
Was=10 % Stop band amplitude weight
ftp=0.3 % Delay pass band edge
tp=101 % Nominal FRM filter delay
tpr=tp/101 % Peak-to-peak pass band delay ripple
Wtp=0.02 % Pass band delay weight
fpp=0.3 % Phase pass band edge
pp=0*pi % Nominal passband phase (adjusted for delay)
ppr=pi/100 % Peak-to-peak pass band phase ripple
Wpp=0.01 % Pass band phase weight
rho=0.968750 % Constraint on allpass pole radius
```

Both the FIR masking filters are symmetric and have length 41. The initial filter is designed by the Octave script *tarczynski_frm_allpass_test.m* with the WISE method of *Tarczynski et al.* as shown in Section 8.1.5. The response of the initial filter is shown in Figure 10.90. After SOCP and PCLS optimisation of the initial filter the resulting model filter all-pass Schur lattice filter has coefficients:

```
k1 = [ -0.0146211106,    0.5777414027,    0.0181702261,   -0.1428708243, ...
       -0.0045559735,    0.0545939011,    0.0099115903,   -0.0279491983, ...
       -0.0043777543,    0.0086675795 ]';
epsilon1 = [  1,   1,  -1,   1, ...
             1,  -1,  -1,   1, ...
             1,  -1 ];
```

The distinct coefficients of the FIR masking filter polynomial are

```
u1 = [  0.5698720310,    0.3066139370,   -0.0622874460,   -0.0846974802, ...

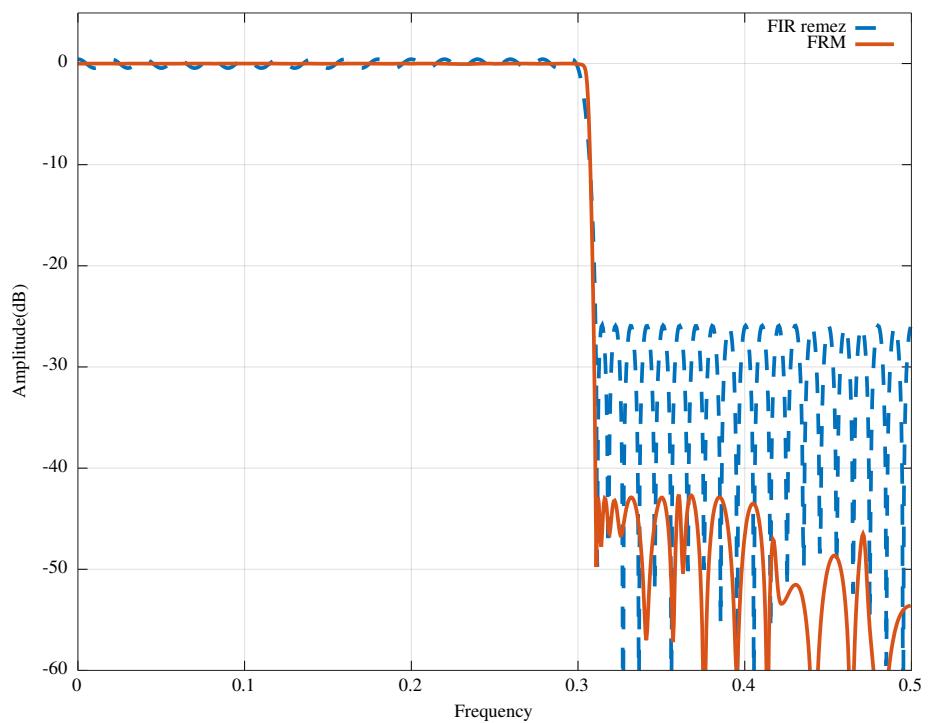

Figure 10.104: Comparison of the amplitude responses of an FRM filter with Schur one-multiplier lattice allpass model filter and a linear-phase FIR filter having a similar number of distinct coefficients.

10.4.7 Design of an FRM half-band digital filter with an allpass Schur lattice model filter using SOCP and PCLS optimisation

Milić et al. describe the design of an FRM half-band filter with the structure shown in Figure 10.78. In this case the model filters are synthesised as the parallel combination of a pure delay, $S(z) = z^{-D}$ and an all-pass filter with coefficients only in z^2 , $R(z^2)$. The coefficients of the denominator polynomial of $R(z^2)$ are r_k . The masking filters are symmetric FIR filters with even order N_m , a multiple of 4 and delay $d = \frac{N_m}{2}$. The transfer function of the FRM half-band filter is:

$$\begin{aligned} H(z) &= \frac{1}{2} [R(z^{2M}) + z^{-DM}] F_{M_a}(z) + \frac{1}{2} [R(z^{2M}) - z^{-DM}] F_{M_c}(z) \\ &= \frac{1}{2} R(z^{2M}) [F_{M_a}(z) + F_{M_c}(z)] + \frac{1}{2} z^{-DM} [F_{M_a}(z) - F_{M_c}(z)] \end{aligned}$$

where M is the decimation factor of the model filter. The nominal delay of the FRM filter is $DM + d$.

The power-complementary branches of a half-band filter are symmetric in frequency. Section 10.4.1 shows the calculation of the band edges of the masking filters required for the FRM filter corresponding to these model filters. Saramäki et al. [156, Figure 2] show that the masking filters of the FRM half-band filter are related by:

$$F_{M_c}(z) = -z^{-d} + F_{M_a}(-z)$$

The polyphase decomposition of $F_{M_a}(z)$ is:

$$F_{M_a}(z) = U(z^2) + z^{-1}V(z^2)$$

where $U(z)$ is a symmetric FIR filter with even order $\frac{N_m}{2}$ and $V(z)$ is a symmetric FIR filter with odd order $\frac{N_m}{2} - 1$.

The transfer function of the FRM half-band filter is, in terms of the polyphase decomposition of F_{M_a} :

$$\begin{aligned} F_{M_a}(z) + F_{M_c}(z) &= 2U(z^2) - z^{-d} \\ F_{M_a}(z) - F_{M_c}(z) &= 2z^{-1}V(z^2) + z^{-d} \end{aligned}$$

so that:

$$H(z) = \frac{1}{2} z^{-DM-d} + \frac{1}{2} [R(z^{2M}) (2U(z^2) - z^{-d}) + 2z^{-DM} z^{-1} V(z^2)]$$

It is convenient to express $U(z^2)$ and $z^{-1}V(z^2)$ in terms of the coefficients, u_k and v_k :

$$\begin{aligned} U(z^2) &= \sum_{k=0}^d u_k z^{-2k} \\ &= u_{\frac{d}{2}} z^{-d} + \sum_{k=0}^{\frac{d}{2}-1} u_k z^{-2k} + \sum_{k=\frac{d}{2}+1}^d u_k z^{-2k} \\ &= u_{\frac{d}{2}} z^{-d} + \sum_{k=0}^{\frac{d}{2}-1} u_k (z^{-2k} + z^{2k-2d}) \\ &= z^{-d} \left[u_{\frac{d}{2}} + \sum_{k=0}^{\frac{d}{2}-1} u_k (z^{-2k+d} + z^{2k-d}) \right] \end{aligned}$$

and:

$$\begin{aligned} z^{-1}V(z^2) &= z^{-1} \sum_{k=0}^{d-1} v_k z^{-2k} \\ &= z^{-1} \sum_{k=0}^{\frac{d}{2}-1} v_k z^{-2k} + z^{-1} \sum_{k=\frac{d}{2}}^{d-1} v_k z^{-2k} \\ &= z^{-1} \sum_{k=0}^{\frac{d}{2}-1} v_k (z^{-2k} + z^{2k-2d+2}) \end{aligned}$$

$$= z^{-d} \sum_{k=0}^{\frac{d}{2}-1} v_k (z^{-2k+d-1} + z^{2k-d+1})$$

Rearranging $H(z)$:

$$H(z) = z^{-DM-d} \left[z^{DM} R(z^{2M}) \left(-\frac{1}{2} + z^d U(z^2) \right) + \left(\frac{1}{2} + z^d z^{-1} V(z^2) \right) \right]$$

so that the zero-phase frequency response of the half-band FRM filter, $H(z)$, is:

$$H(\omega) = e^{j[DM\omega + \phi_R(2M\omega)]} A(\omega) + B(\omega)$$

where $\phi_R(2M\omega)$ is the phase response of the all-pass filter $R(z^{2M})$ and:

$$\begin{aligned} A(\omega) &= -\frac{1}{2} + u_{\frac{d}{2}} + \sum_{k=0}^{\frac{d}{2}-1} 2u_k \cos[\omega(2k-d)] \\ B(\omega) &= \frac{1}{2} + \sum_{k=0}^{\frac{d}{2}-1} 2v_k \cos[\omega(2k-d+1)] \end{aligned}$$

The squared-magnitude and phase responses of the zero phase response of the FRM half-band filter are similar to those shown in Section 10.4.4:

$$\begin{aligned} |H(\omega)|^2 &= A^2(\omega) + B^2(\omega) + 2A(\omega)B(\omega) \cos \phi_Z(M\omega) \\ \phi_H(\omega) &= \arctan \frac{A(\omega) \sin \phi_Z(M\omega)}{A(\omega) \cos \phi_Z(M\omega) + B(\omega)} \end{aligned}$$

where $\phi_Z(\omega) = D\omega + \phi_R(2\omega)$.

The group delay response, $T(\omega)$, of the zero phase response of the FRM half-band filter is given by:

$$\begin{aligned} |H(\omega)|^2 T(\omega) &= - (A^2(\omega) + A(\omega)B(\omega) \cos \phi_Z(M\omega)) \frac{\partial \phi_Z(M\omega)}{\partial \omega} \dots \\ &\quad - \sin \phi_Z(M\omega) \left[B(\omega) \frac{\partial A(\omega)}{\partial \omega} - A(\omega) \frac{\partial B(\omega)}{\partial \omega} \right] \end{aligned}$$

where:

$$\begin{aligned} \frac{\partial A(\omega)}{\partial \omega} &= -2 \sum_{k=0}^{\frac{d}{2}-1} (2k-d) u_k \sin[\omega(2k-d)] \\ \frac{\partial B(\omega)}{\partial \omega} &= -2 \sum_{k=0}^{\frac{d}{2}-1} (2k-d+1) v_k \sin[\omega(2k-d+1)] \end{aligned}$$

The gradients of $|H(\omega)|^2$ with respect to the coefficients are:

$$\begin{aligned} \frac{\partial |H(\omega)|^2}{\partial r_k} &= -2A(\omega)B(\omega) \sin \phi_Z(M\omega) \frac{\partial \phi_R(2M\omega)}{\partial r_k} \\ \frac{\partial |H(\omega)|^2}{\partial u_k} &= 2(A(\omega) + B(\omega) \cos \phi_Z(M\omega)) \frac{\partial A(\omega)}{\partial u_k} \\ \frac{\partial |H(\omega)|^2}{\partial v_k} &= 2(B(\omega) + A(\omega) \cos \phi_Z(M\omega)) \frac{\partial B(\omega)}{\partial v_k} \end{aligned}$$

and:

$$\begin{aligned} \frac{\partial A(\omega)}{\partial u_k} &= \begin{cases} 1 & k = \frac{d}{2} \\ 2 \cos[\omega(2k-d)] & otherwise \end{cases} \\ \frac{\partial B(\omega)}{\partial v_k} &= 2 \cos[\omega(2k-d+1)] \end{aligned}$$

The gradients of $T(\omega)$ with respect to the coefficients are given by:

$$\begin{aligned}\frac{\partial |H(\omega)|^2}{\partial r_k} T(\omega) + |H(\omega)|^2 \frac{\partial T(\omega)}{\partial r_k} &= (A^2(\omega) + A(\omega)B(\omega)\cos\phi_Z(M\omega)) \frac{\partial^2 \phi_R(2M\omega)}{\partial \omega \partial r_k} \dots \\ &\quad + A(\omega)B(\omega)\sin\phi_Z(M\omega) \frac{\partial \phi_Z(M\omega)}{\partial \omega} \frac{\partial \phi_R(2M\omega)}{\partial r_k} \dots \\ &\quad - \cos\phi_Z(M\omega) \left[B(\omega) \frac{\partial A(\omega)}{\partial \omega} - A(\omega) \frac{\partial B(\omega)}{\partial \omega} \right] \frac{\partial \phi_R(2M\omega)}{\partial r_k} \\ \frac{\partial |H(\omega)|^2}{\partial u_k} T(\omega) + |H(\omega)|^2 \frac{\partial T(\omega)}{\partial u_k} &= -(2A(\omega) + B(\omega)\cos\phi_Z(M\omega)) \frac{\partial \phi_Z(M\omega)}{\partial \omega} \frac{\partial A(\omega)}{\partial u_k} \dots \\ &\quad - \sin\phi_Z(M\omega) \left[B(\omega) \frac{\partial^2 A(\omega)}{\partial \omega \partial u_k} - \frac{\partial B(\omega)}{\partial \omega} \frac{\partial A(\omega)}{\partial u_k} \right] \\ \frac{\partial |H(\omega)|^2}{\partial v_k} T(\omega) + |H(\omega)|^2 \frac{\partial T(\omega)}{\partial v_k} &= -A(\omega)\cos\phi_Z(M\omega) \frac{\partial \phi_Z(M\omega)}{\partial \omega} \frac{\partial B(\omega)}{\partial v_k} \dots \\ &\quad - \sin\phi_Z(M\omega) \left[\frac{\partial A(\omega)}{\partial \omega} \frac{\partial B(\omega)}{\partial v_k} - A(\omega) \frac{\partial^2 B(\omega)}{\partial \omega \partial v_k} \right]\end{aligned}$$

The Octave script `schurOneMAPlattice_frm_halfband_socp_slb_test.m` designs an FRM half-band filter with a model filter implemented as a Schur one-multiplier all-pass lattice. The filter specification is:

```
tol=1e-05 % Tolerance on coefficient update vector
ctol=1e-07 % Tolerance on constraints
n=800 % Frequency points across the band
mr=5 % Allpass model filter denominator order
na=33 % FIR masking filter length (order+1)
Mmodel=7 % Model filter FRM decimation factor
Dmodel=9 % Model filter nominal pass band group delay
dmask=16 % FIR masking filter delay
Tnominal=79 % Nominal FRM filter group delay
fap=0.24 % Pass band edge
dBap=0.05 % Pass band amplitude peak-to-peak ripple
Wap=1 % Pass band weight
tpr=0.335 % Pass band delay peak-to-peak ripple
Wtp=0.2 % Pass band delay weight
fas=0.26 % Stop band edge
dBas=45 % Stop band attenuation ripple
Was=100 % Stop band weight
rho=0.968750 % Constraint on all-pass lattice coefficients
```

The initial filter is designed by the Octave script `tarczynski_frm_halfband_test.m` with the WISE method of *Tarczynski et al.* as shown in Section 8.1.5. Figure 10.105 shows the overall response of the initial FRM filter.

SOCP and PCLS optimisation of the initial filter results in a model filter allpass filter with following lattice coefficients:

```
k2 = [ 0.5530908702, -0.1250393727, 0.0415215054, -0.0135148726, ...
0.0023471213 ]';
```

```
epsilon2 = [ 1, 1, -1, 1, ...
-1 ];
```

The FIR masking filter polynomials are:

```
u2 = [ -0.0004880213, 0.0023491483, -0.0070017092, 0.0130026516, ...
-0.0309751474, 0.0346130567, -0.0508817539, 0.0580181001, ...
0.4385471578 ]';
```

```
v2 = [ 0.0066015766, -0.0044701172, 0.0066994268, -0.0031082142, ...
-0.0069727257, 0.0306836611, -0.0815291960, 0.3141854206 ]';
```

Figure 10.106 shows the overall response of the resulting SOCP optimised, PCLS constrained FRM filter. Figure 10.107 shows the passband response of the resulting FRM filter. Figure 10.108 shows the responses of the resulting FRM masking filters. Figure 10.109 shows the response of the resulting FRM model filter.

10.4.8 Design of an FRM Hilbert digital filter with an allpass Schur lattice model filter using SOCP and PCLS optimisation

Milić et al. [80] point out that shifting the transfer function of the FRM half-band filter, $H(z)$, of Section 10.4.7, right-wards by $\frac{\pi}{2}$ along the frequency axis results in a filter, $H_A(z)$, that generates the *analytic* signal. Suppose the half-band filter response is:

$$H(z) = \frac{1}{2}z^{-N} + \frac{1}{2}Q(z^2)$$

where $N + 1$ is a multiple of 4. The filter, $H_A(z)$, that generates the analytic signal is:

$$\begin{aligned} H_A(z) &= 2\imath H(-\imath z) \\ &= z^{-N} + \imath Q(-z^2) \end{aligned}$$

In other words, $H_H(z) = Q(-z^2)$ is a Hilbert transform filter. For convenience, assume that the masking filter order, N_m , is a multiple of 8, that M and D are odd and that $DM + 1$ is a multiple of 4. Then:

$$H_H(z) = R(-z^{2M})(2U(-z^2) - z^{-d}) + 2z^{-DM-1}V(-z^2)$$

where:

$$\begin{aligned} U(-z^2) &= \sum_{k=0}^d u_k (-z^2)^{-k} \\ &= (-1)^{-\frac{d}{2}} u_{\frac{d}{2}} z^{-d} + \sum_{k=0}^{\frac{d}{2}-1} (-1)^{-k} u_k z^{-2k} + \sum_{k=\frac{d}{2}+1}^d (-1)^{-k} u_k z^{-2k} \\ &= u_{\frac{d}{2}} z^{-d} + \sum_{k=0}^{\frac{d}{2}-1} (-1)^{-k} u_k (z^{-2k} + z^{2k-2d}) \\ &= z^{-d} \left[u_{\frac{d}{2}} + \sum_{k=0}^{\frac{d}{2}-1} (-1)^{-k} u_k (z^{-2k+d} + z^{2k-d}) \right] \end{aligned}$$

and:

$$\begin{aligned} z^{-1}V(-z^2) &= z^{-1} \sum_{k=0}^{d-1} v_k (-z^2)^{-k} \\ &= z^{-1} \sum_{k=0}^{\frac{d}{2}-1} (-1)^{-k} v_k z^{-2k} + z^{-1} \sum_{k=\frac{d}{2}}^{d-1} (-1)^{-k} v_k z^{-2k} \\ &= z^{-d} \sum_{k=0}^{\frac{d}{2}-1} (-1)^{-k} v_k (z^{-2k+d-1} - z^{2k-d+1}) \end{aligned}$$

If $r(z^2)$ is the denominator polynomial of the prototype all-pass filter prototype, $R(z^2)$, then:

$$\begin{aligned} R(-z^2) &= \frac{(-z^{-2})^{N_{model}} r(-z^{-2})}{r(-z^2)} \\ &= (-1)^{N_{model}} \frac{z^{-2N_{model}} r(-z^{-2})}{r(-z^2)} \end{aligned}$$

where N_{model} is the order of $r(z)$. If N_{model} is odd then the zero frequency gain of $R(-z^2)$ is -1 .

For convenience, rename the FRM Hilbert filter coefficients in terms of the coefficients of the FRM half-band filter as $r'_k = (-1)^{-k} r_k$, $u'_k = (-1)^{-k} u_k$ and $v'_k = (-1)^{-k} v_k$. The zero-phase frequency response of the Hilbert filter, $H_H(z)$, is:

$$H_H(\omega) = e^{i[D M \omega + \phi_{R_H}(2M\omega)]} A_H(\omega) + \imath B_H(\omega)$$

where:

$$A_H(\omega) = -1 + 2u'_{\frac{d}{2}} + 4 \sum_{k=0}^{\frac{d}{2}-1} u'_k \cos[\omega(2k-d)]$$

$$B_H(\omega) = -4 \sum_{k=0}^{\frac{d}{2}-1} v'_k \sin [\omega(2k-d+1)]$$

and $\phi_{R_H}(2M\omega)$ is the phase response of the modified all-pass filter $R_H(z^{2M}) = R(-z^{2M})$.

The squared-magnitude and phase responses of the zero phase response of the FRM Hilbert filter are:

$$|H_H(\omega)|^2 = A_H^2(\omega) + B_H^2(\omega) + 2A_H(\omega)B_H(\omega)\sin\phi_{Z_H}(M\omega)$$

and:

$$\phi_{H_H}(\omega) = \arctan \frac{A_H(\omega)\sin\phi_{Z_H}(M\omega) + B_H(\omega)}{A_H(\omega)\cos\phi_{Z_H}(M\omega)}$$

where $\phi_{Z_H}(\omega) = D\omega + \phi_{R_H}(2\omega)$.

The group delay response, $T_H(\omega)$, of the zero phase response of the FRM Hilbert filter is given by:

$$\begin{aligned} |H_H(\omega)|^2 T_H(\omega) &= - (A_H^2(\omega) + A_H(\omega)B_H(\omega)\sin\phi_{Z_H}(M\omega)) \frac{\partial\phi_{Z_H}(M\omega)}{\partial\omega} \dots \\ &\quad + \cos\phi_{Z_H}(M\omega) \left[B_H(\omega) \frac{\partial A_H(\omega)}{\partial\omega} - A_H(\omega) \frac{\partial B_H(\omega)}{\partial\omega} \right] \end{aligned}$$

where:

$$\begin{aligned} \frac{\partial A_H(\omega)}{\partial\omega} &= -4 \sum_{k=0}^{\frac{d}{2}-1} (2k-d) u'_k \sin [\omega(2k-d)] \\ \frac{\partial B_H(\omega)}{\partial\omega} &= -4 \sum_{k=0}^{\frac{d}{2}-1} (2k-d+1) v'_k \cos [\omega(2k-d+1)] \end{aligned}$$

The gradients of $|H_H(\omega)|^2$ with respect to the coefficients are:

$$\begin{aligned} \frac{\partial |H_H(\omega)|^2}{\partial r'_k} &= 2A_H(\omega)B_H(\omega)\cos\phi_{Z_H}(M\omega) \frac{\partial\phi_{R_H}(2M\omega)}{\partial r'_k} \\ \frac{\partial |H_H(\omega)|^2}{\partial u'_k} &= 2(A_H(\omega) + B_H(\omega)\sin\phi_{Z_H}(M\omega)) \frac{\partial A_H(\omega)}{\partial u'_k} \\ \frac{\partial |H_H(\omega)|^2}{\partial v'_k} &= 2(B_H(\omega) + A_H(\omega)\sin\phi_{Z_H}(M\omega)) \frac{\partial B_H(\omega)}{\partial v'_k} \end{aligned}$$

where:

$$\begin{aligned} \frac{\partial A_H(\omega)}{\partial u'_k} &= \begin{cases} 1 & k = \frac{d}{2} \\ 4\cos[\omega(2k-d)] & otherwise \end{cases} \\ \frac{\partial B_H(\omega)}{\partial v'_k} &= -4\sin[\omega(2k-d+1)] \end{aligned}$$

The gradients of $\phi_{H_H}(\omega)$ with respect to the coefficients are given by:

$$\begin{aligned} |H_H(\omega)|^2 \frac{\partial\phi_{H_H}(\omega)}{\partial r'_k} &= (A_H^2(\omega) + A_H(\omega)B_H(\omega)\sin\phi_{Z_H}(M\omega)) \frac{\partial\phi_{Z_H}(2M\omega)}{\partial\omega} \\ |H_H(\omega)|^2 \frac{\partial\phi_{H_H}(\omega)}{\partial u'_k} &= -B_H(\omega)\cos\phi_{Z_H}(M\omega) \frac{\partial A_H(\omega)}{\partial u'_k} \\ |H_H(\omega)|^2 \frac{\partial\phi_{H_H}(\omega)}{\partial v'_k} &= A_H(\omega)\cos\phi_{Z_H}(M\omega) \frac{\partial B_H(\omega)}{\partial v'_k} \end{aligned}$$

The gradients of $T_H(\omega)$ with respect to the coefficients are given by:

$$\frac{\partial |H_H(\omega)|^2}{\partial r'_k} T_H(\omega) + |H_H(\omega)|^2 \frac{\partial T_H(\omega)}{\partial r'_k} = -A_H(\omega)B_H(\omega)\cos\phi_{Z_H}(M\omega) \frac{\partial\phi_{Z_H}(M\omega)}{\partial\omega} \frac{\partial\phi_{R_H}(2M\omega)}{\partial r'_k} \dots$$

$$\begin{aligned}
& - (A_H^2(\omega) + A_H(\omega)B_H(\omega)\sin\phi_{Z_H}(M\omega)) \frac{\partial^2\phi_{Z_H}(M\omega)}{\partial\omega\partial r'_k} \dots \\
& - \sin\phi_{Z_H}(M\omega) \left[B_H(\omega) \frac{\partial A_H(\omega)}{\partial\omega} - A_H(\omega) \frac{\partial B_H(\omega)}{\partial\omega} \right] \frac{\partial\phi_{R_H}(2M\omega)}{\partial r'_k} \\
\frac{\partial |H_H(\omega)|^2}{\partial u'_k} T_H(\omega) + |H_H(\omega)|^2 \frac{\partial T_H(\omega)}{\partial u'_k} & = - (2A_H(\omega) + B_H(\omega)\sin\phi_{Z_H}(M\omega)) \frac{\partial\phi_{Z_H}(M\omega)}{\partial\omega} \frac{\partial A_H(\omega)}{\partial u'_k} \dots \\
& + \cos\phi_{Z_H}(M\omega) \left[B_H(\omega) \frac{\partial^2 A_H(\omega)}{\partial\omega\partial u'_k} - \frac{\partial B_H(\omega)}{\partial\omega} \frac{\partial A_H(\omega)}{\partial u'_k} \right] \\
\frac{\partial |H_H(\omega)|^2}{\partial v'_k} T_H(\omega) + |H_H(\omega)|^2 \frac{\partial T_H(\omega)}{\partial v'_k} & = - A_H(\omega)\sin\phi_{Z_H}(M\omega) \frac{\partial\phi_{Z_H}(M\omega)}{\partial\omega} \frac{\partial B_H(\omega)}{\partial v'_k} \dots \\
& + \cos\phi_{Z_H}(M\omega) \left[\frac{\partial A_H(\omega)}{\partial\omega} \frac{\partial B_H(\omega)}{\partial v'_k} - A_H(\omega) \frac{\partial^2 B_H(\omega)}{\partial\omega\partial v'_k} \right]
\end{aligned}$$

where:

$$\begin{aligned}
\frac{\partial^2 A_H(\omega)}{\partial\omega\partial u'_k} &= -4(2k-d)\sin[\omega(2k-d)] \\
\frac{\partial^2 B_H(\omega)}{\partial\omega\partial v'_k} &= -4(2k-d+1)\cos[\omega(2k-d+1)]
\end{aligned}$$

The Octave script *schurOneMAPlattice_frm_hilbert_socp_slb_test.m* designs an FRM Hilbert filter with an all-pass model filter implemented as a Schur one-multiplier lattice. The filter specification is:

```

n=800 % Frequency points

Part III

Design of IIR filters with integer coefficients

This part describes the results of my experiments in optimising the response of digital filters with integer coefficients expressed in *signed-digit* form. A coefficient approximated with a small number of signed-digits can be implemented with *shift-and-add* operations. Chapter 11 describes the conversion of coefficients to signed-digit form and two heuristics for allocating the number of signed-digits used by each coefficient. The remaining chapters in this part consider methods of searching for the signed-digit approximations to the coefficients that give an acceptable filter response.

Chapter 11

Signed-digit representation of filter coefficients

Hwang [72, Section 1.5] defines *signed-digit* numbers as follows:

Given a radix r , each digit of a signed-digit number can assume the following $2\alpha + 1$ values:

$$\Sigma_r = \{-\alpha, \dots, -1, 0, 1, \dots, \alpha\}$$

where the maximum digit magnitude, α , must be within the following region:

$$\lceil \frac{r-1}{2} \rceil \leq \alpha \leq r-1$$

Because integer $\alpha \geq 1, r \geq 2$ must be assumed. In order to yield *maximum redundancy* in the balanced digit set Σ_r , one can choose the following value for the maximum magnitude

$$\alpha = \lfloor \frac{r}{2} \rfloor$$

Further:

The original motivation of using signed-digit number system is to eliminate carry propagation chains in addition (or subtraction). To break the carry chain, the lower bound on α should be made tighter as

$$\lceil \frac{r+1}{2} \rceil \leq \alpha \leq r-1$$

Parhi [73, Section 13.6] lists the following properties of the *canonical* binary signed-digit (CSD) representation of a binary signed-digit number $A = a_{W-1}a_{W-2}\cdots a_1a_0$ where each $a_i \in \{-1, 0, 1\}$:

- no 2 consecutive bits in a CSD number are non-zero
- the CSD representation of a number contains the minimum possible number of non-zero bits, thus the name *canonical*
- the CSD representation of a number is unique
- CSD numbers cover the range $(-\frac{4}{3}, \frac{4}{3})$, out of which the values in the range $[-1, 1]$ are of greatest interest
- among the W -bit CSD numbers in the range $[-1, 1]$, the average number of nonzero bits is $\frac{W}{3} + \frac{1}{9} + \mathcal{O}(2^{-W})$. Hence, on average, the CSD representation contains about two-thirds the number of non-zero bits of the equivalent two's complement representation.

Parhi [73, Section 13.6.1] shows an algorithm that calculates the *canonical* binary signed-digit representation from the two's complement representation, reproduced here as Algorithm 11.1.

The Octave function `bin2SPT` converts a two's complement number to the canonical signed-digit representation. The Octave function `bin2SD` approximates an `nbits` two's complement number by the `ndigits` signed-digit representation.

Algorithm 11.1 Conversion of 2's complement numbers to the canonical signed-digit representation (*Parhi [73, Section 13.6.1]*).

Denote the two's complement representation of the number A as $A = \hat{a}_{W-1}\hat{a}_{W-2}\cdots\hat{a}_1\hat{a}_0$.

Denote the CSD representation of A as $A = a_{W-1}a_{W-2}\cdots a_1a_0$.

```

 $\hat{a}_{-1} = 0$ 
 $\gamma_{-1} = 0$ 
 $\hat{a}_W = \hat{a}_{W-1}$ 
for  $k = 0, \dots, W-1$  do
     $\theta_i = \hat{a}_i \oplus \hat{a}_{i-1}$ 
     $\gamma_i = \bar{\gamma}_{i-1}\theta_i$ 
     $a_i = (1 - 2\hat{a}_{i+1})\gamma_i$ 
end for
```

11.1 Lim's method for allocating signed-digits to filter coefficients

Lim et al. [173] describe a method of allocating a limited number of signed power-of-two digit terms to the fixed-point coefficients of a digital filter. The method is based on the belief that “*allocating the SPT terms in such a way that all the coefficient values have the same quantization step-size to coefficient sensitivity ratio will lead to a good design*”.

Lim et al. first prove properties of the signed-digit representation [173, Section II]. In particular:

Property 1: Define S_Q as the set of contiguous integers that can be represented by up to Q signed digits. The largest integer in S_Q is $J_Q = \sum_{l=0}^{Q-1} 2^{2l+1}$.

Property 2: For $n = \sum_{l=0}^{L-1} s_l 2^l$ with $s_l \in \{-1, 0, 1\}$ it is always possible to find a representation for n such that no two consecutive signed-digits are non-zero: $s_l s_{l+1} = 0$ for all l .

Property 5: On average, $0.72Q$ signed-digits are required to represent the integers in S_Q .

Lim et al. show that an estimate of the number of signed digits, Q , required to represent J_Q is:

$$Q \approx \frac{1}{2} \log_2 J_Q + 0.31$$

Replacing J_Q by an integer $n \in S_Q$, an estimate of the average number of terms, Q_A , required to represent n is:

$$\begin{aligned} Q_A &\approx 0.72Q \\ &\approx 0.36 \log_2 n + 0.22 \end{aligned}$$

Now suppose that R signed digits are available to represent two positive integers n_1 and n_2 . If $n_1 \approx n_2$ then each integer is allocated $\frac{R}{2}$ bits. If $n_1 > n_2$ then *Lim et al.* argue that the number of additional signed-digits, Q_E , required to represent n_1 is:

$$Q_E \approx 0.36 \log_2 \lfloor \frac{n_1}{n_2} \rfloor$$

where $\lfloor x \rfloor$ represents the integer part of x . In general, Q_E is not an integer.

Lim et al. go on to consider the allocation of signed digits to the coefficients of a symmetric FIR filter. The change in the frequency response, $\Delta H(\omega)$ of a filter due to a change Δx_k in coefficient x_k is:

$$\Delta H(\omega, k) \approx \frac{\partial H(\omega)}{\partial x_k} \Delta x_k$$

Lim et al. use the average of the coefficient sensitivity to define a cost, c_k , for the k 'th coefficient:

$$c_k = 0.36 \log_2 |x_k| + 0.36 \log_2 \int_0^\pi \left| \frac{\partial H(\omega)}{\partial x_k} \right| d\omega$$

Given a total of R signed-digits, *Lim et al.* assign a single signed-digit at a time to the coefficient with the largest cost. After a coefficient is given a signed-digit, its cost is decreased by one. The process is repeated until all R digits have been allocated.

11.2 Ito's method for allocating signed-digits to filter coefficients

Ito *et al.* [136] describe a heuristic for allocating signed-digits to the coefficients of an FIR filter. Suppose $\mathbf{x} = \{x_1, \dots, x_K\}$ are the exact coefficients of the filter and that each x_k is approximated by an L signed-digit number, \hat{x}_k , and there are a total of R signed digits to be allocated:

$$\hat{x}_k = \sum_{l=1}^{n_k} b_{k,l} 2^{-q_{k,l}}$$

where

$$\begin{aligned} b_{k,l} &\in \{-1, 1\} \\ q_{k,l} &\leq L \\ R &\geq \sum_{k=1}^K n_k \end{aligned}$$

The heuristic of Ito *et al.* allocates the R available signed digits to the coefficients \mathbf{x} . $c(\mathbf{x})$ is a cost function for the filter design and \mathbf{e}_k is the unit vector with a 1 in the k 'th position and 0 elsewhere. In this case, $\lceil x_k \rceil$ is defined to be the least CSD upper bound to x_k and $\lfloor x_k \rfloor$ is defined to be the greatest CSD lower bound to x_k . I have modified the heuristic described by Ito *et al.* to that shown in Algorithm 11.2 by beginning with an allocation of $2N$ signed digits to each non-zero coefficient (where N is the desired average number of signed-digits per coefficient) and then iteratively removing digits from coefficients with the lowest cost. At each iteration the new cost for the coefficient is recalculated.

Algorithm 11.2 Modified signed-digit allocation heuristic of Ito *et al.* [136]

Initialise n_k :

```
for  $k = 1, \dots, K$  do
  if  $|x_k| < \epsilon$  then
     $n_k = 0$ 
  else
     $n_k = 2N$ 
  end if
end for
```

Allocate n_k :

```
for  $r = 2R, \dots, R$  do
  for  $k = 1, \dots, K$  do
    if  $n_k \geq 1$  then
       $c_k^U = c(\mathbf{x} + (\lceil x_k \rceil - x_k) \mathbf{e}_k)$ 
       $c_k^L = c(\mathbf{x} - (x_k - \lfloor x_k \rfloor) \mathbf{e}_k)$ 
       $c_k = \min \{c_k^L, c_k^U\}$ 
    end if
  end for
   $c_{k_{min}} = \min \{c_k\}$ 
   $n_{k_{min}} = 1$ 
end for
```

11.3 Signed-digit allocation of the coefficients of a Schur one-multiplier lattice filter

This section compares the performance of the SQP optimised Schur one-multiplier bandpass filter of Section 10.3.3 with coefficients that are exact, rounded, approximated by two signed-digits and approximated by an average of two and three signed-digits allocated by the Lim and Ito heuristics, implemented in the Octave script *schurOneMlattice_bandpass_allocsd_test.m*. That script designs a Schur IIR tapped-lattice band-pass filter for which the denominator of the transfer function has coefficients only in z^{-2} the amplitude passband is $[0.1, 0.2]$, the lower amplitude stopband is $[0, 0.05]$, the upper amplitude stopband is $[0.25, 0.5]$ and the passband group delay is $t_d = 16$ samples over $[0.09, 0.21]$. There are 31 non-zero lattice coefficients to be truncated. I assume that the internal state scaling for round-off noise reduction is approximated by bit-shifts. The heuristic of Lim *et al.* is implemented in the Octave function *schurOneMlattice_allocsd_Lim* and the heuristic of Ito *et al.* is implemented in the Octave function *schurOneMlattice_allocsd_Ito.m*. The function *schurOneMlattice_allocsd_Lim* allocates signed digits according to the gradients of the un-weighted sum of the squared-magnitude and group-delay errors.

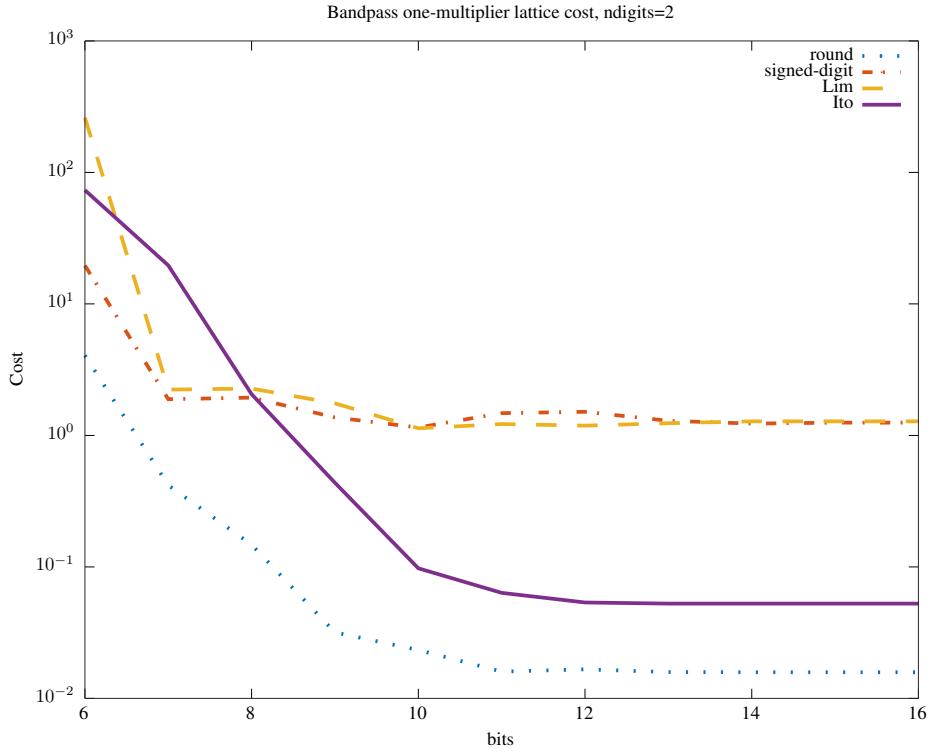

Figure 11.1: Comparison of the cost function for a Schur one-multiplier lattice bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by two signed-digits and approximation by an average of two signed digits using the heuristics of *Lim et al.* and *Ito et al.*

Figure 11.1 compares the cost for each allocation method, Figure 11.2 compares the maximum stopband response in the frequency range [0.26, 0.5], Figure 11.3 compares the total number of signed-digits required to implement the coefficient multipliers for 2 signed-digits allocated to each non-zero coefficient and Figure 11.4 compares the estimated filter noise-gain using word-sizes of 6 to 16 bits. Figure 11.5 compares the responses for 10-bit coefficients and Figure 11.6 compares the passband responses for 10-bit 2-signed-digit coefficients.

Figures 11.7, 11.8, 11.9, 11.10, 11.11 and 11.12 show the corresponding results for an allocation of 3 signed-digits to each non-zero 10-bit coefficient. For the heuristic of *Ito et al.*, when 3 bits are allocated to each non-zero coefficient approximately 2 signed-digits per coefficient are in fact used.

This filter has been designed with denominator polynomial coefficients only in powers of z^{-2} so that the filter can be retimed with reduced latency for the state update and filter output calculations. (As shown in Figure 5.27). The noise gain of the retimed filter is calculated by converting the lattice filter representation to state variable form with the Octave function `schurOneMR2lattice2Abcd`. The noise gain of the filter with exact coefficients is 3.44804. A fixed point implementation of the filter would either scale the states with bit-shifts (ie: by a power of two) or by adding bits to the state registers as required. In the results shown here the noise gain calculated for the retimed filter with truncated coefficients does not include the round-off noise due to state scaling.

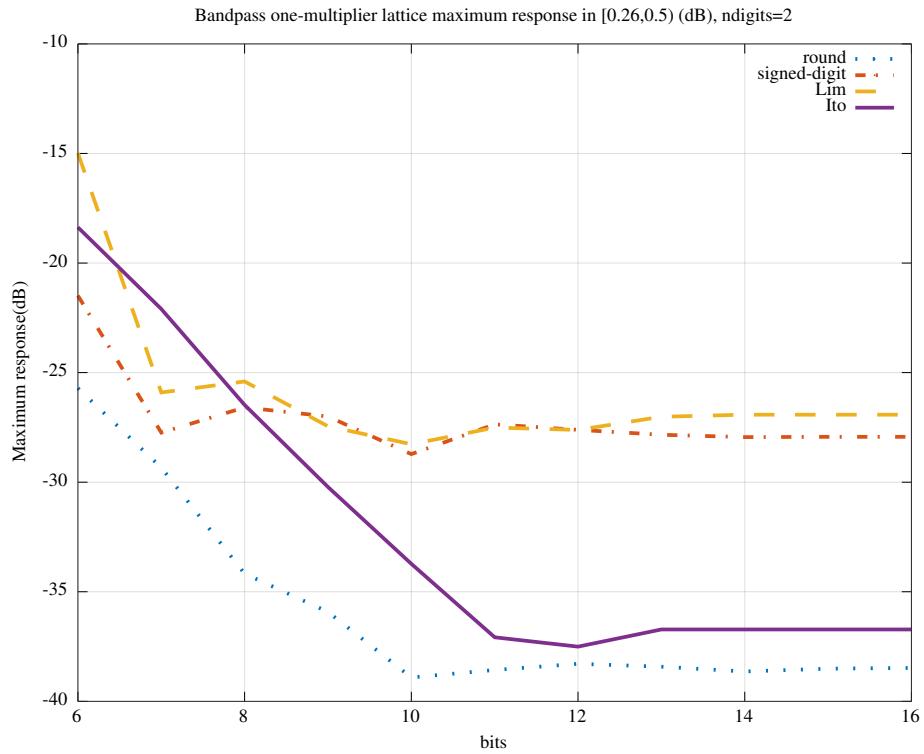

Figure 11.2: Comparison of the maximum stopband response in the region [0.26,0.5) for a Schur one-multiplier lattice bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by two signed-digits and approximation by an average of two signed digits using the heuristics of *Lim et al.* and *Ito et al.*

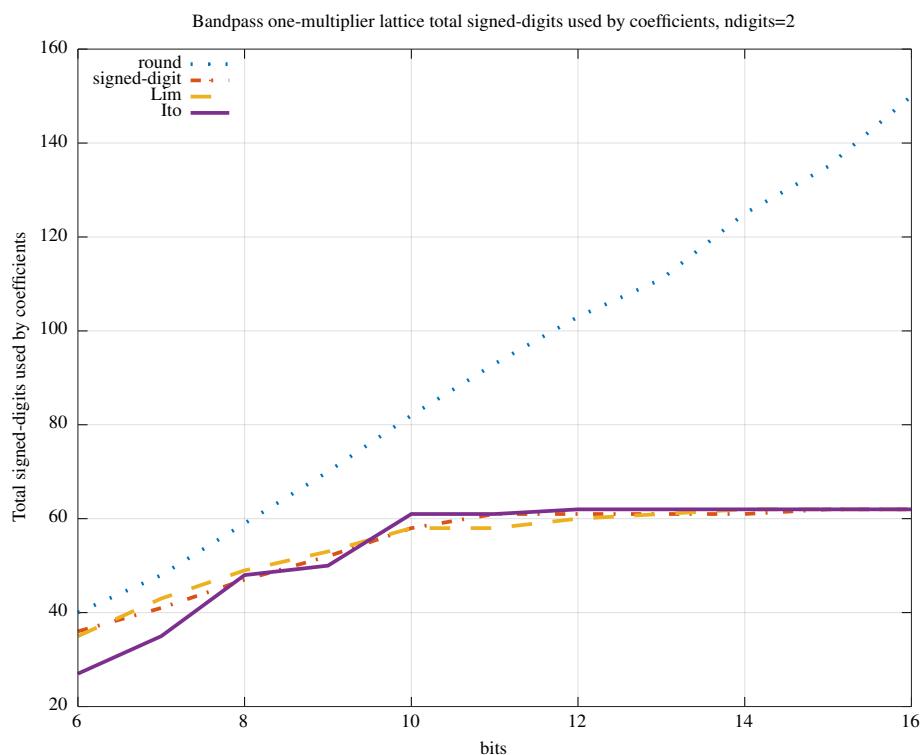

Figure 11.3: Comparison of the total number of signed-digits required to implement the coefficients of a Schur one-multiplier lattice bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by two signed-digits and approximation by an average of two signed digits using the heuristics of *Lim et al.* and *Ito et al.*

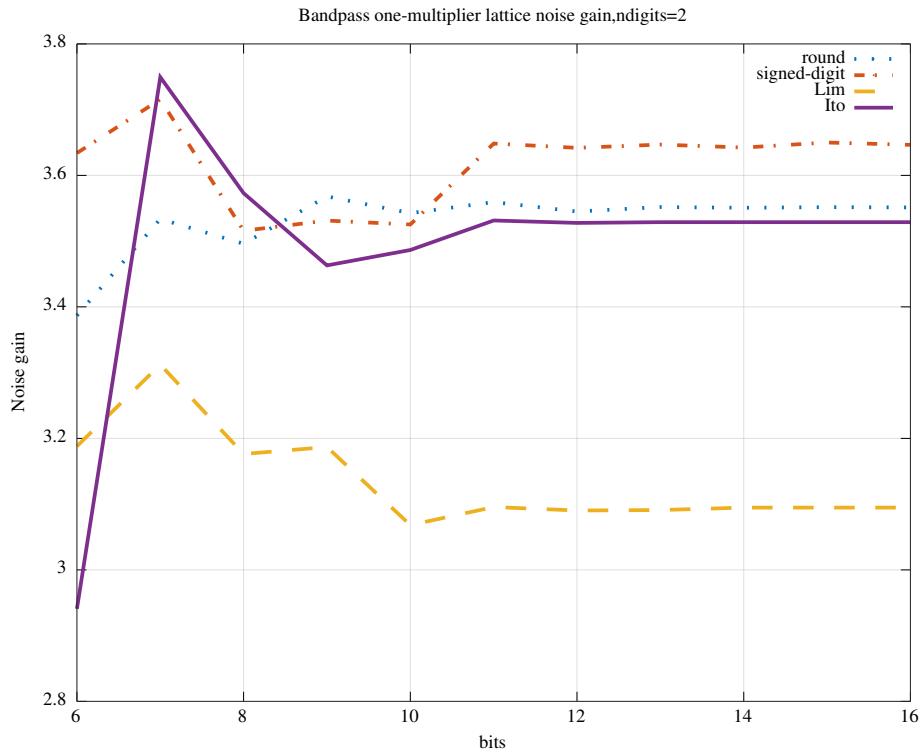

Figure 11.4: Comparison of the estimated noise gain of a Schur one-multiplier lattice bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by two signed-digits and approximation by an average of two signed digits using the heuristics of *Lim et al.* and *Ito et al.*.

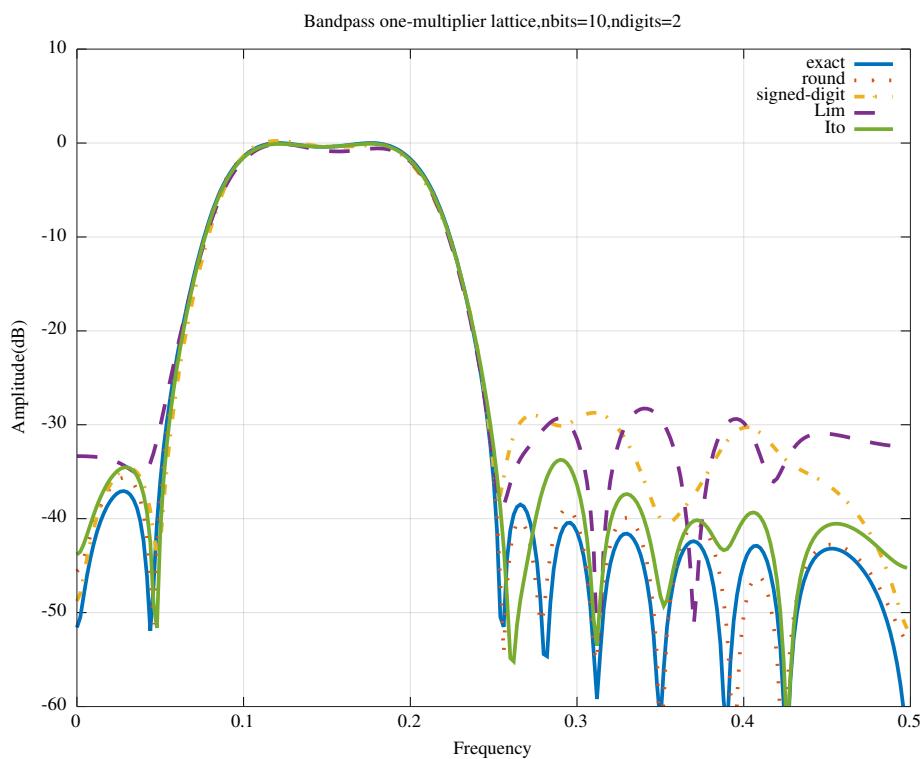

Figure 11.5: Comparison of the responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by rounding, approximation by two signed-digits and approximation by an average of two signed digits using the heuristics of *Lim et al.* and *Ito et al.*

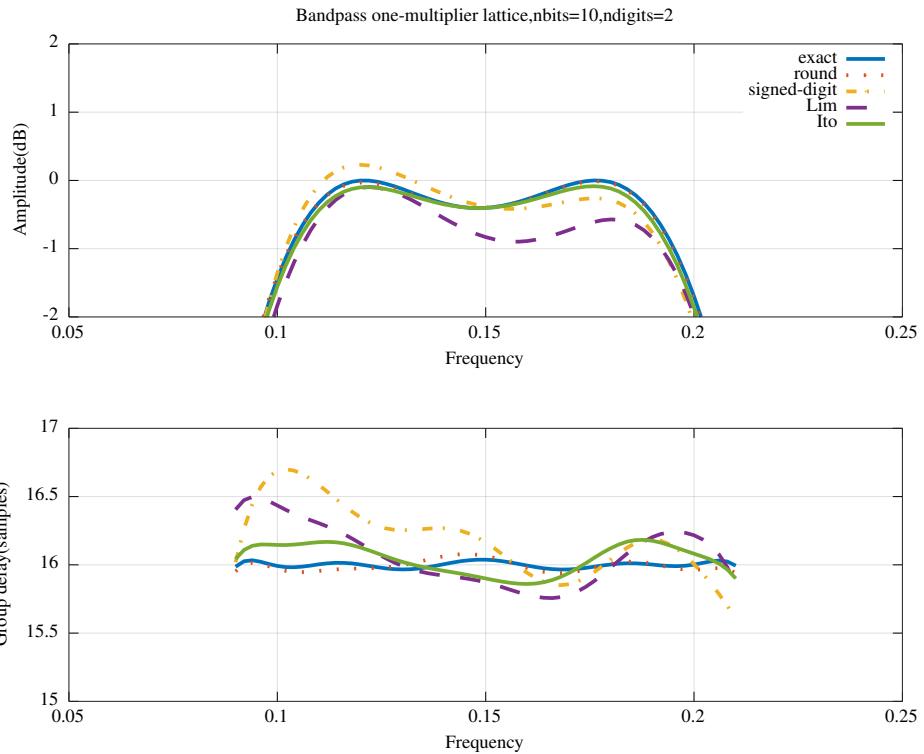

Figure 11.6: Comparison of the passband responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by rounding, approximation by two signed-digits and approximation by an average of two signed digits using the heuristics of *Lim et al.* and *Ito et al.*

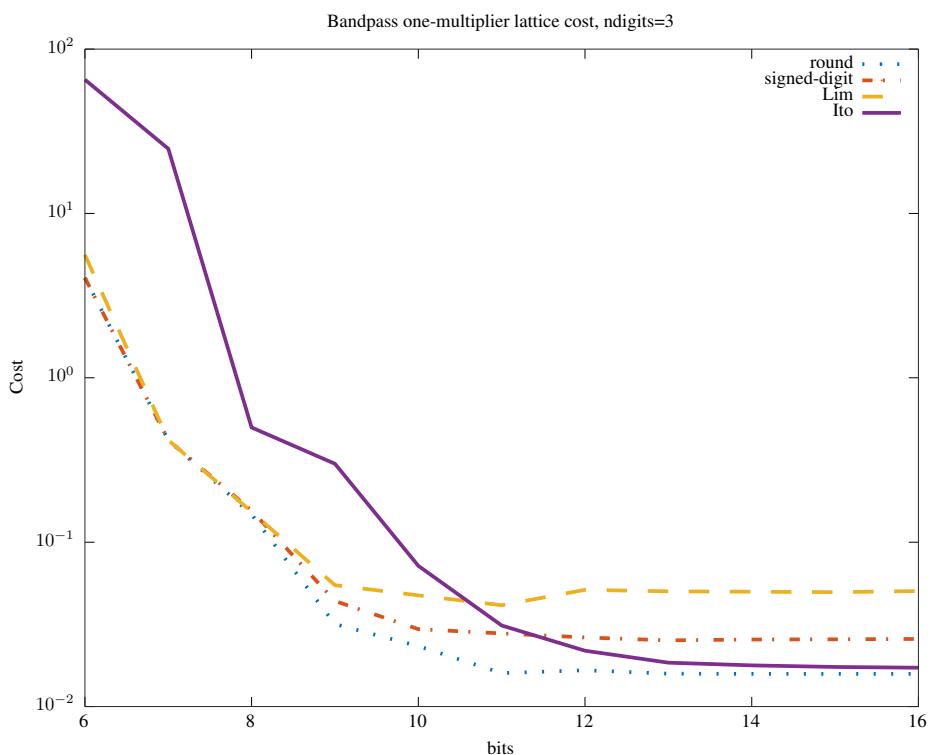

Figure 11.7: Comparison of the cost function for a Schur one-multiplier lattice bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by three signed-digits and approximation by an average of three signed digits using the heuristics of *Lim et al.* and *Ito et al.*

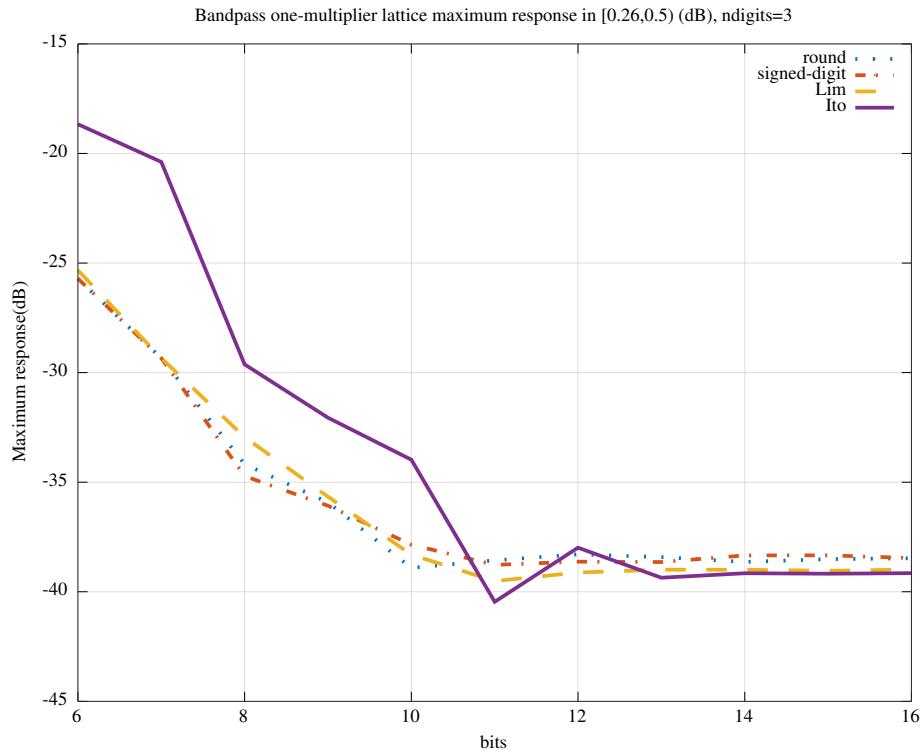

Figure 11.8: Comparison of the maximum stopband response in the region [0.26,0.5) for a Schur one-multiplier lattice bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by three signed-digits and approximation by an average of three signed digits using the heuristics of *Lim et al.* and *Ito et al.*

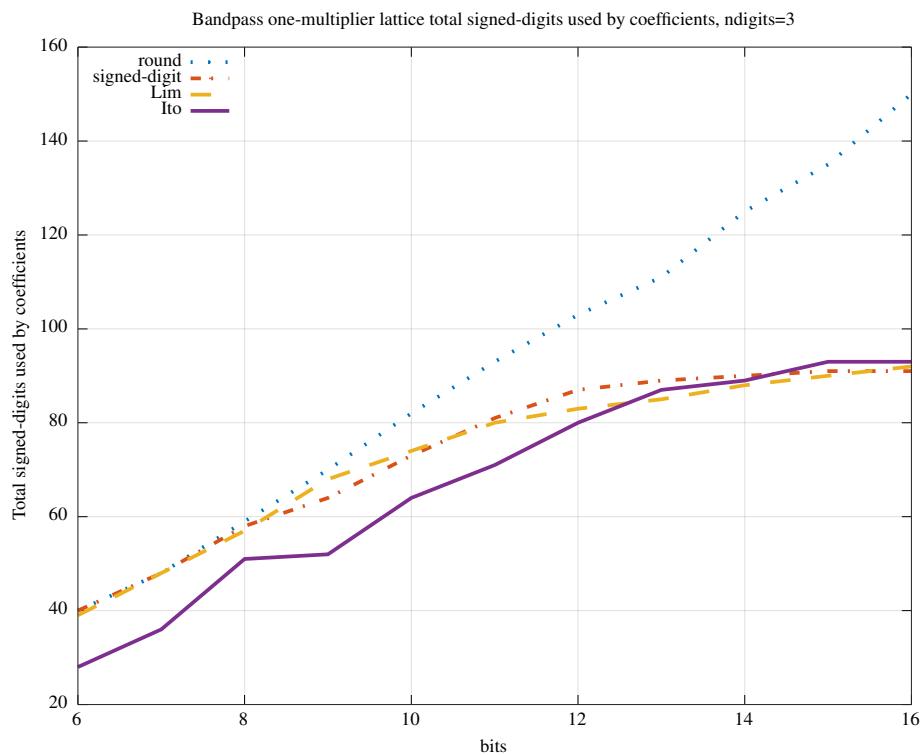

Figure 11.9: Comparison of the total number of signed-digits required to implement the coefficients of a Schur one-multiplier lattice bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by three signed-digits and approximation by an average of three signed digits using the heuristics of *Lim et al.* and *Ito et al.*

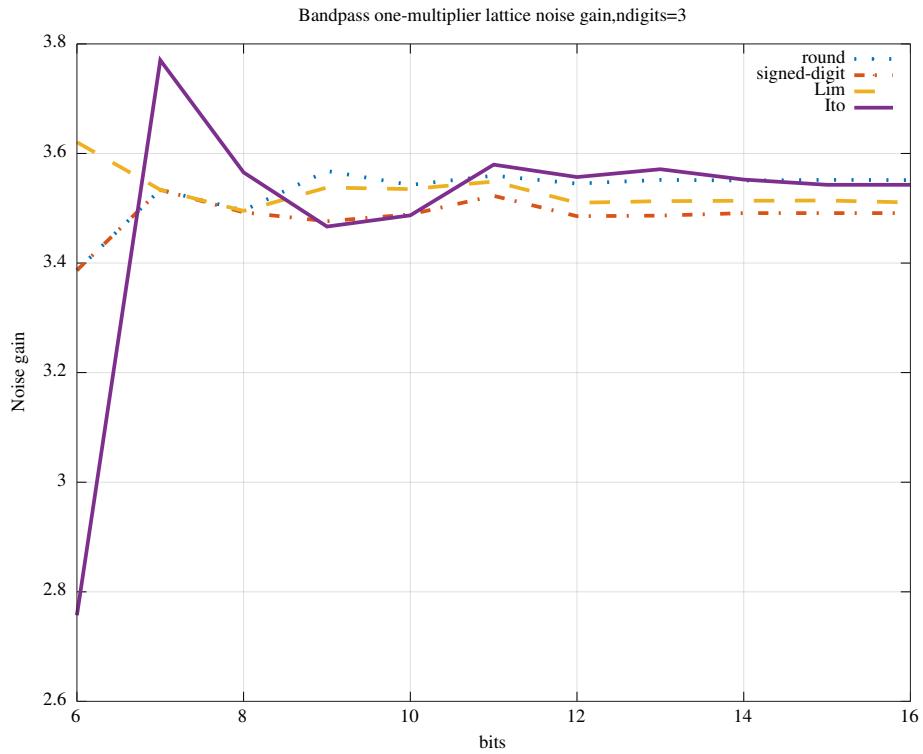

Figure 11.10: Comparison of the estimated noise gain of a Schur one-multiplier lattice bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by three signed-digits and approximation by an average of two signed digits using the heuristics of *Lim et al.* and *Ito et al.*.

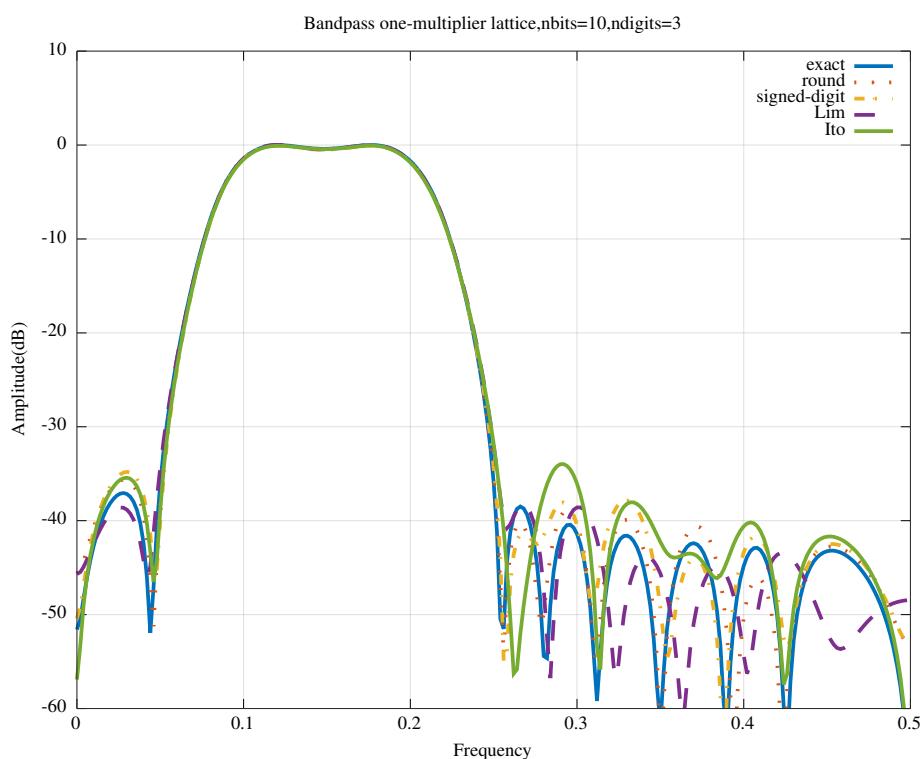

Figure 11.11: Comparison of the responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by rounding, approximation by three signed-digits and approximation by an average of three signed digits using the heuristics of *Lim et al.* and *Ito et al.*.

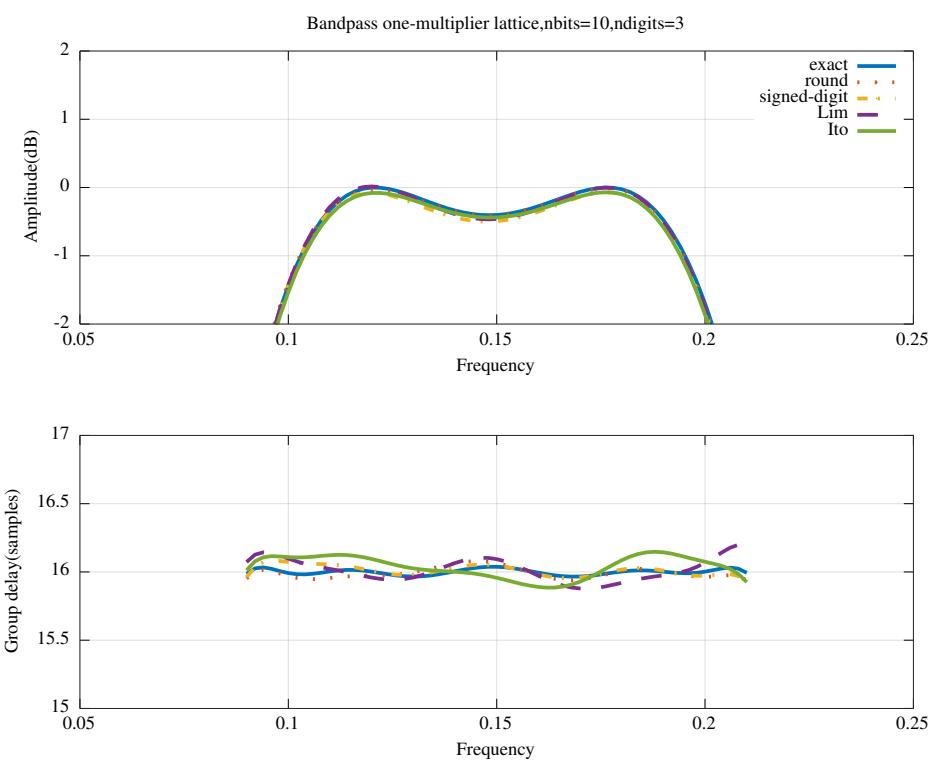

Figure 11.12: Comparison of the passband responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by rounding, approximation by three signed-digits and approximation by an average of three signed digits using the heuristics of *Lim et al.* and *Ito et al.*

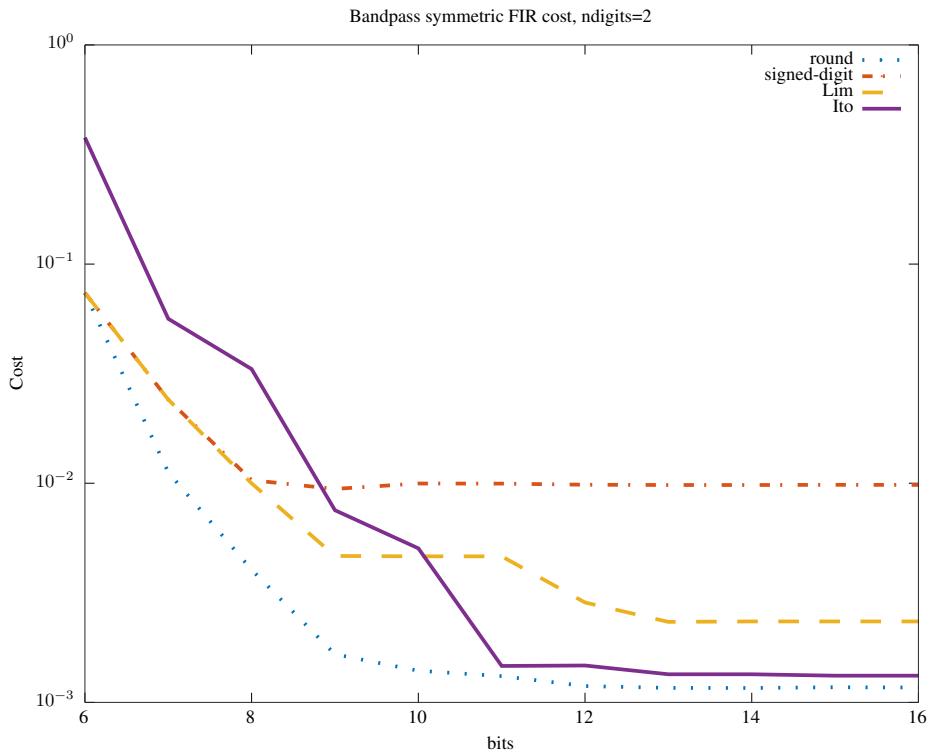

Figure 11.13: Comparison of the cost function for a direct-form even-order symmetric FIR bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by two signed-digits and approximation by an average of two signed digits using the heuristics of *Lim et al.* and *Ito et al.*

11.4 Signed-digit allocation of the coefficients of a symmetric FIR band-pass filter

Appendix L.2 describes the optimisation of even-order symmetric direct-form FIR filters with constraints on the amplitude response by the method of Lagrange multipliers. This section compares the performance of a direct-form even-order symmetric FIR bandpass with coefficients that are exact, rounded, approximated by two signed-digits and approximated by an average of two and three signed-digits allocated by the *Lim* and *Ito* heuristics. The comparison is implemented in the Octave script *directFIRsymmetric_bandpass_allocsd_test.m*. That script calls the Octave function *directFIRsymmetric_slb* to design a symmetric FIR band-pass filter polynomial of order 30 with 16 distinct coefficients. The filter amplitude passband is [0.1, 0.2], the lower amplitude stopband is [0, 0.05] and the upper amplitude stopband is [0.25, 0.5]. The heuristic of *Lim et al.* is implemented in the Octave function *directFIRsymmetric_allocsd_Lim*. That function allocates signed digits according to the gradients of the *un-weighted* sum of the magnitude errors. The heuristic of *Ito et al.* is implemented in the Octave function *directFIRsymmetric_allocsd_Ito.m*.

Figure 11.13 compares the cost for each allocation method, Figure 11.14 compares the maximum stopband response in the frequency range [0.26, 0.5], Figure 11.15 compares the total number of signed-digits required to implement the coefficient multipliers for 2 signed-digits allocated to each non-zero coefficient and Figure 11.16 compares the responses for 10-bit 2-signed-digit coefficients. Figures 11.17, 11.18, 11.19 and 11.20 show the corresponding results for an allocation of 3 signed-digits to each non-zero 10-bit coefficient.

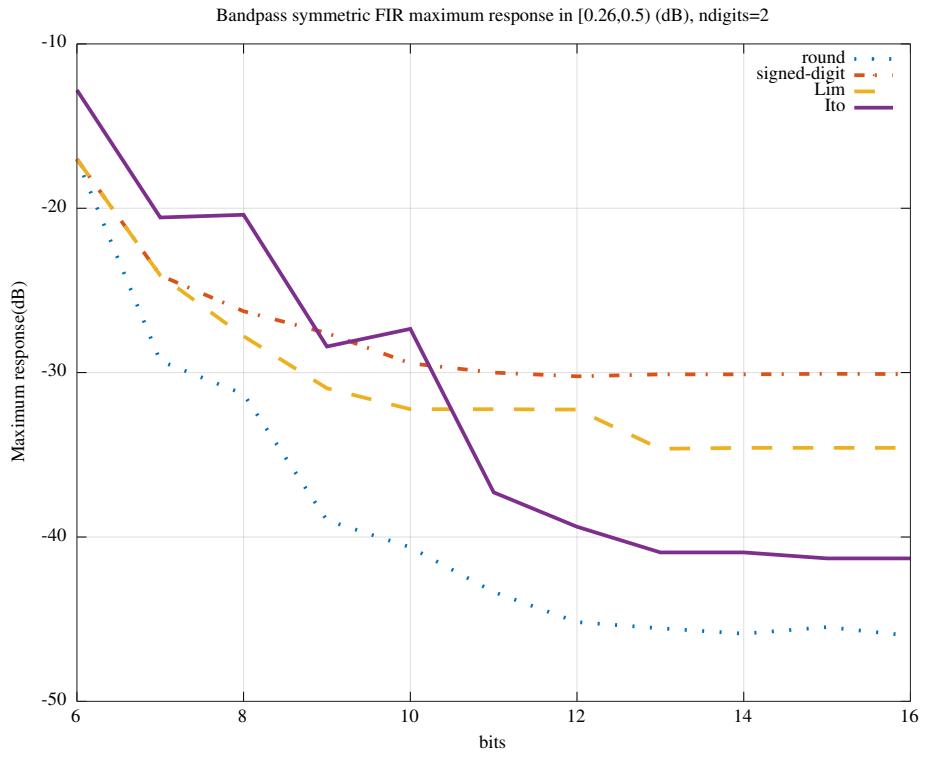

Figure 11.14: Comparison of the maximum stopband response in the region [0.26,0.5) for a direct-form even-order symmetric FIR bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by two signed-digits and approximation by an average of two signed digits using the heuristics of *Lim et al.* and *Ito et al.*

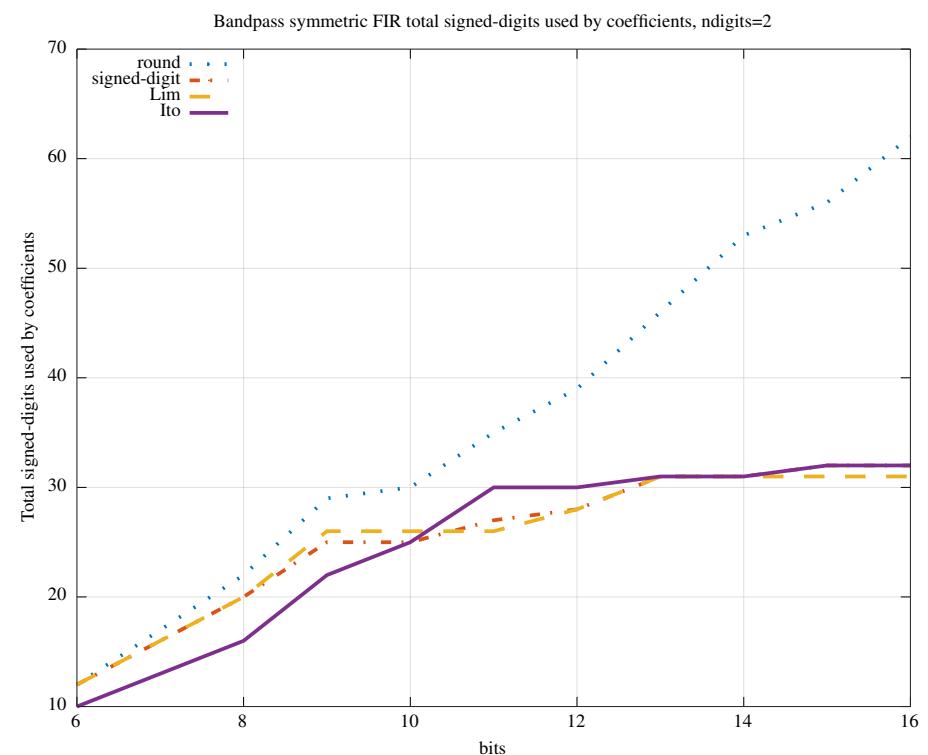

Figure 11.15: Comparison of the total number of signed-digits required to implement the coefficients of a direct-form even-order symmetric FIR bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by two signed-digits and approximation by an average of two signed digits using the heuristics of *Lim et al.* and *Ito et al.*

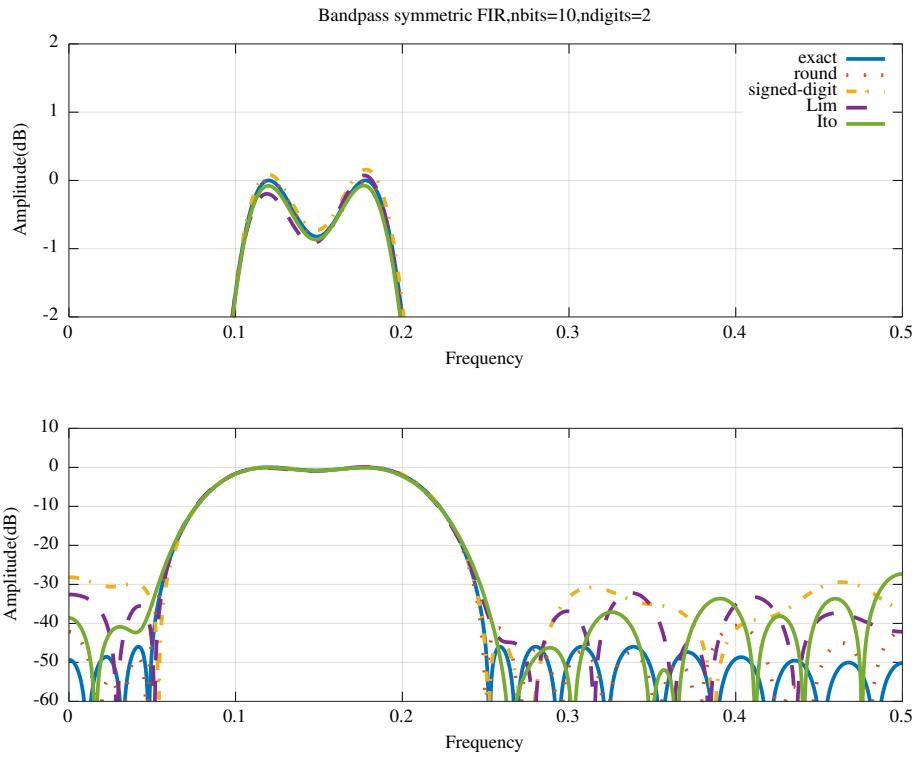

Figure 11.16: Comparison of the responses for a direct-form even-order symmetric FIR bandpass filter with 10-bit integer coefficients found by rounding, approximation by two signed-digits and approximation by an average of two signed digits using the heuristics of *Lim et al.* and *Ito et al.*

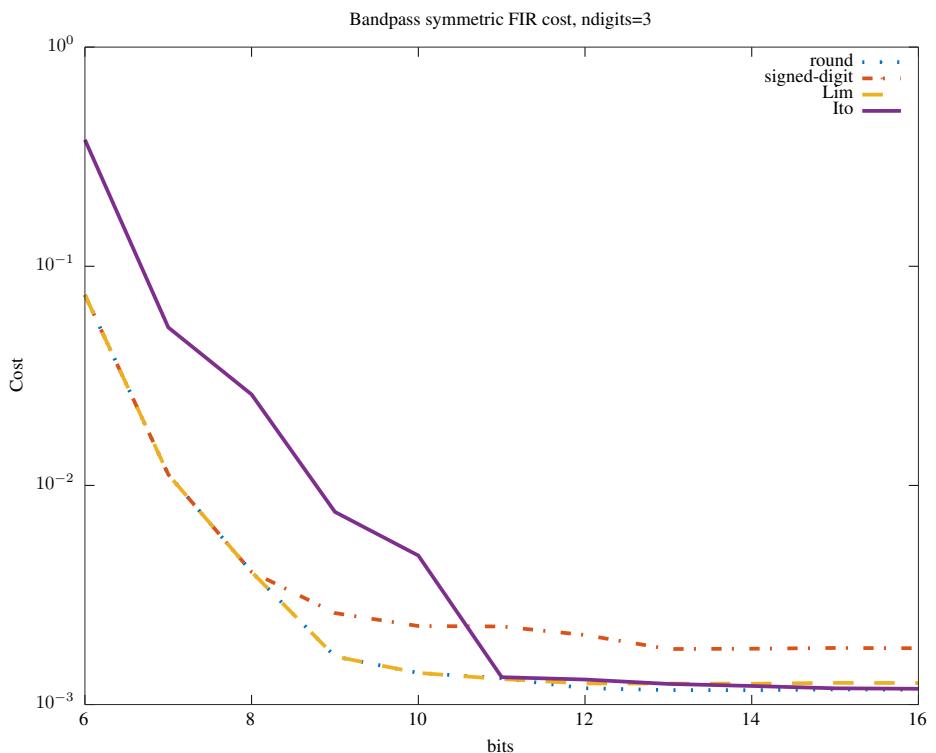

Figure 11.17: Comparison of the cost function for a direct-form even-order symmetric FIR bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by three signed-digits and approximation by an average of three signed digits using the heuristics of *Lim et al.* and *Ito et al.*

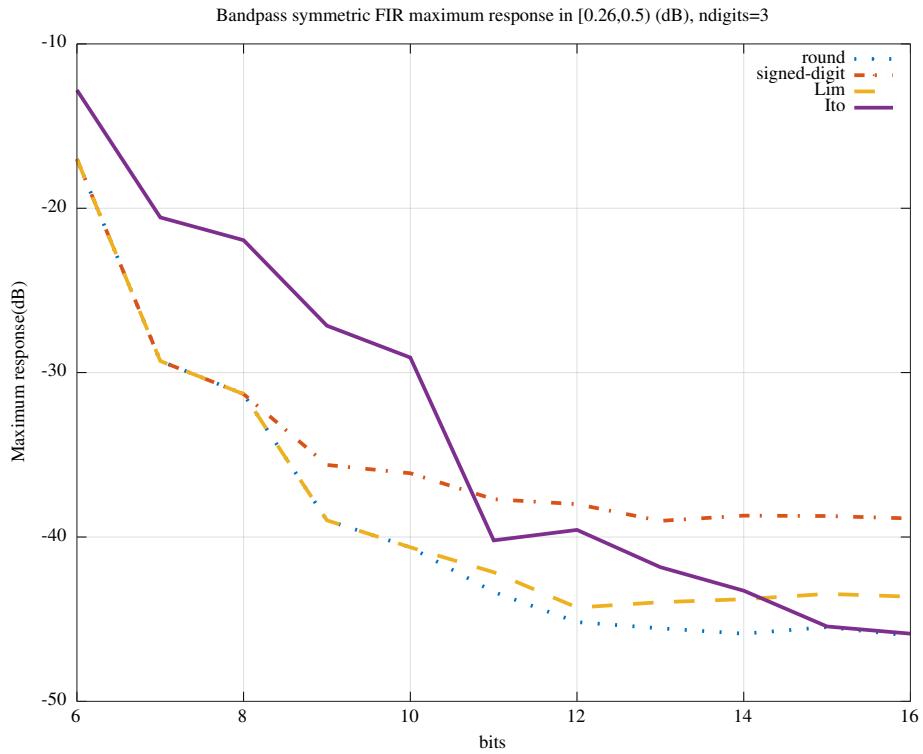

Figure 11.18: Comparison of the maximum stopband response in the region [0.26,0.5) for a direct-form even-order symmetric FIR bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by three signed-digits and approximation by an average of three signed digits using the heuristics of *Lim et al.* and *Ito et al.*

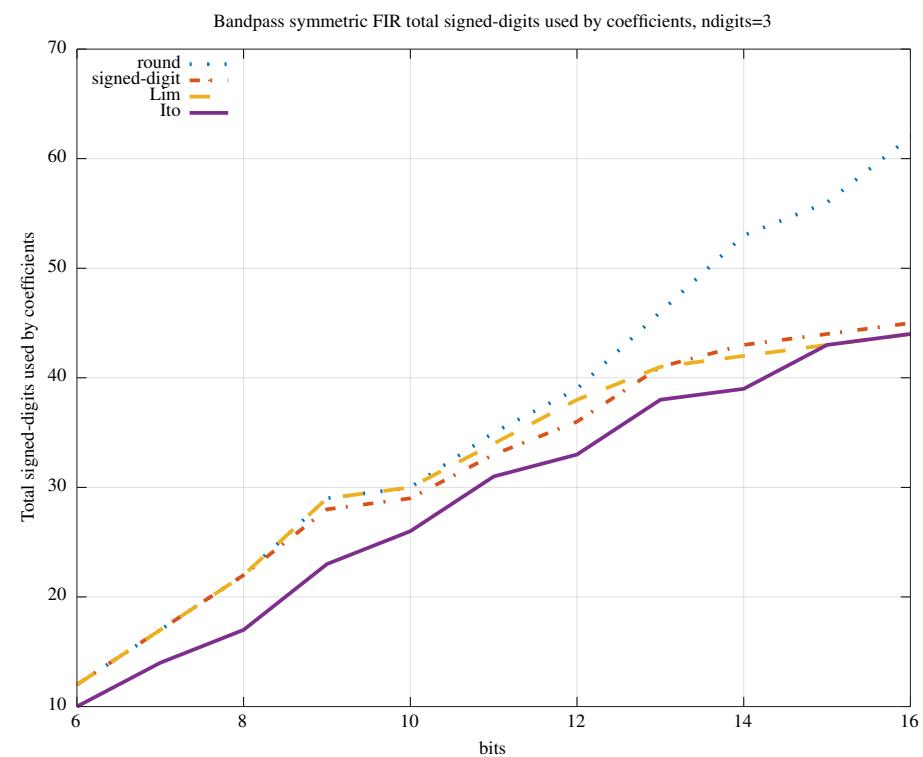

Figure 11.19: Comparison of the total number of signed-digits required to implement the coefficients of a direct-form even-order symmetric FIR bandpass filter with 6-bit to 16-bit integer coefficients found by rounding, approximation by three signed-digits and approximation by an average of three signed digits using the heuristics of *Lim et al.* and *Ito et al.*

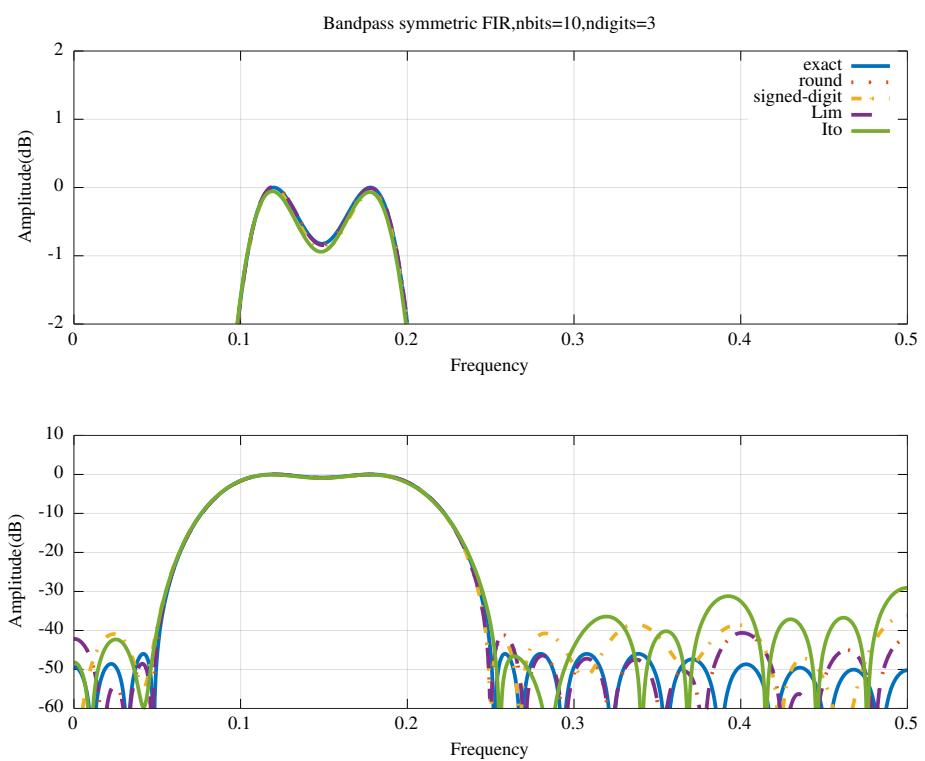

Figure 11.20: Comparison of the responses for a direct-form even-order symmetric FIR bandpass filter with 10-bit integer coefficients found by rounding, approximation by three signed-digits and approximation by an average of three signed digits using the heuristics of *Lim et al.* and *Ito et al.*

Chapter 12

Exhaustive search for integer and signed-digit filter coefficients

The Octave script *exhaustive_schurOneMlattice_bandpass_test.m* implements an exhaustive search for the best signed-digit approximation to the exact coefficients of the Schur one-multiplier lattice band-pass filter designed in Section 10.3.3. The cost function for the search calculates the weighted root-squared-error of the amplitude and group-delay responses of the filter when compared to an ideal “brick-wall” response. The band-pass filter has 31 non-zero coefficients and each coefficient is selected from an upper and lower bound on the exact value so the exhaustive search will perform 2^{31} evaluations of the cost function. Preliminary experiments showed that this script would require about a month of processing time on my PC (which has an Intel i7-7700K CPU with 4 cores running at 4.2GHz).

Chapter 13

Searching for integer and signed-digit filter coefficients with the *bit-flipping* algorithm

Krukowski and Kale [6], describe a “bit-flipping” algorithm for fixed-point filter design, shown in flow-graph form in Figure 13.1 (from [6, Figure 2]).

The bit-flipping algorithm searches for an improvement in a cost-function by testing each combination of bits within a window for each coefficient. When no further improvement is found the window is shifted toward the least-significant-bits and the search is repeated. The bit-flipping algorithm is implemented in the Octave function *bitflip*.

In the following examples I apply the bit-flipping algorithm to direct-form, Schur normalised-scaled lattice and Schur one-multiplier lattice IIR filter implementations.

The initial IIR filter is that designed by the Octave script *iir_sqp_slb_bandpass_test.m* with:

```
fapl=0.1          % Amplitude passband lower edge (fs=1)
faph=0.2          % Amplitude passband upper edge
dBap=1           % Amplitude passband ripple (dB)
ftpl=0.09         % Group delay passband lower edge
ftph=0.21         % Group delay passband upper edge
tp=16            % Passband group delay (samples)
tpr=0.08          % Passband group delay ripple
fasl=0.05         % Amplitude lower stopband upper edge
fasl=0.25         % Amplitude upper stopband lower edge
dBas=35           % Amplitude stopband attenuation
```

For completeness, I also apply the bit-flipping algorithm to the coefficients of a minimum-phase Schur FIR lattice band-pass filter and a direct-form linear-phase symmetric FIR band-pass filter having the desired frequency bands. The parallel allpass one-multiplier Schur lattice filter has amplitude response constraints of $dBap = 2$ and $dBas = 53$. The Schur FIR lattice has amplitude response constraints of $dBap = 3$ and $dBas = 25$. The direct-form symmetric FIR filter has amplitude response constraints of $dBap = 2$ and $dBas = 46$.

For each example a cost function compares an ideal, “brick-wall” response with the responses for the exact filter coefficients and the filter coefficients approximated by 8-bit rounded, 8-bit rounding optimised with the bit-flipping algorithm, 8-bit 2-signed-digits and 8-bit 2-signed-digits optimised with the bit-flipping algorithm. The cost function weights the stop-band amplitude error by $W_{asl} = W_{asu} = 30$. Bit-flipping starts at bit 6 of 8 bits and uses a mask size of 3 bits.

13.1 Bit-flipping search for the signed-digit coefficients of a direct-form bandpass IIR filter

The Octave script *bitflip_directIIR_bandpass_test.m* applies the bit-flipping algorithm to a direct-form IIR bandpass filter with the following filter transfer function polynomials:

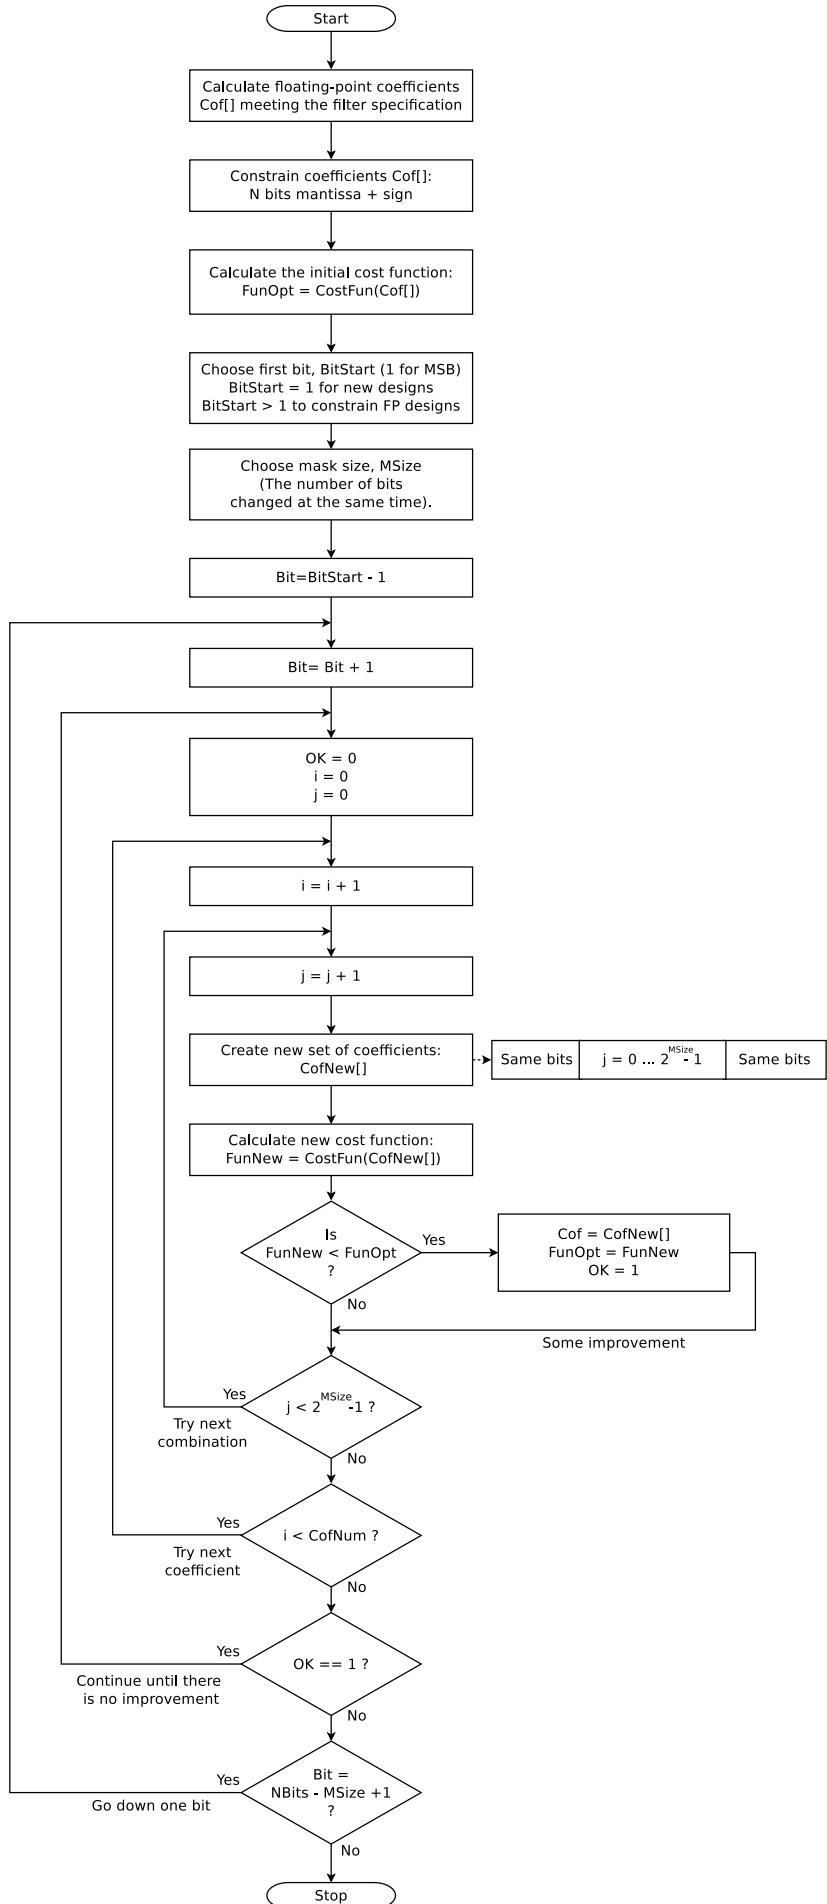

Figure 13.1: The bit-flipping algorithm. (Krukowski and Kale [6, Figure 2]).

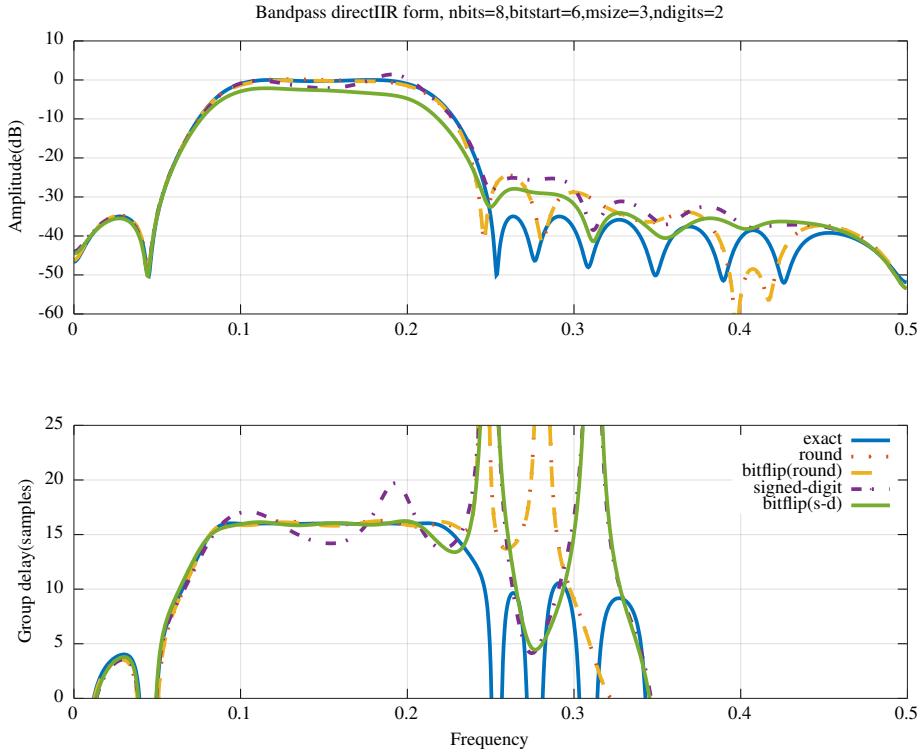

Figure 13.2: Amplitude and group-delay responses of a direct-form IIR band-pass filter with exact coefficients, 8-bit rounded coefficients, 8-bit rounded coefficients optimised with the bit-flipping algorithm, 8-bit 2-signed-digit coefficients and 8-bit 2-signed-digit coefficients optimised with the bit-flipping algorithm

```

  128,      128,      128,      128 ]'/128;
```

A total of 59 adders is required to implement these signed-digit coefficients.

13.3 Bit-flipping search for the signed-digit coefficients of a one-multiplier lattice bandpass IIR filter

The Octave script *bitflip_schurOneMlattice_bandpass_test.m* applies the bit-flipping algorithm to the example bandpass filter implemented as a Schur one-multiplier lattice filter. Note that, in this example, the one-multiplier state scaling coefficients are not truncated.

The filter responses are shown in Figure 13.4.

The filter responses for the signed-digit coefficients with 2-signed-digits, 2-signed-digits allocated with Lim's algorithm and 2-signed-digits allocated with Ito's algorithm are shown in Figure 13.5.

Table 13.3 compares the cost result for each test.

The *bitflip* optimised 8-bit, rounded, one-multiplier lattice bandpass filter coefficients are:

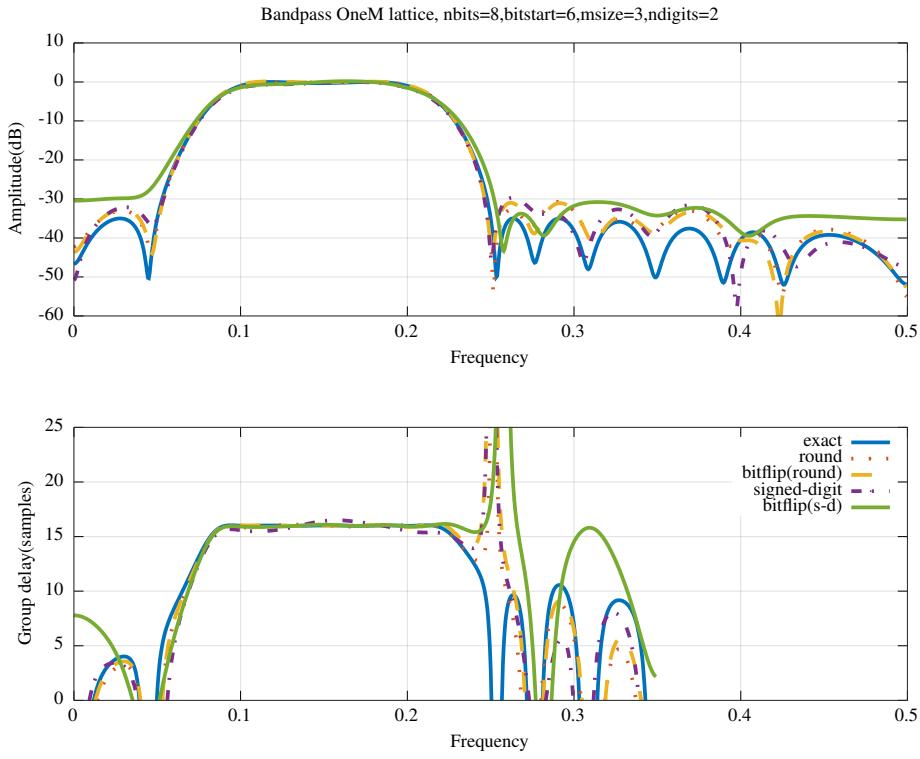

Figure 13.4: Amplitude and group-delay responses of a band-pass filter synthesised as a one-multiplier lattice filter with exact coefficients, 8-bit rounded coefficients, 8-bit rounded coefficients optimised with the bit-flipping algorithm, 8-bit 2-signed-digit coefficients and 8-bit 2-signed-digit coefficients optimised with the bit-flipping algorithm

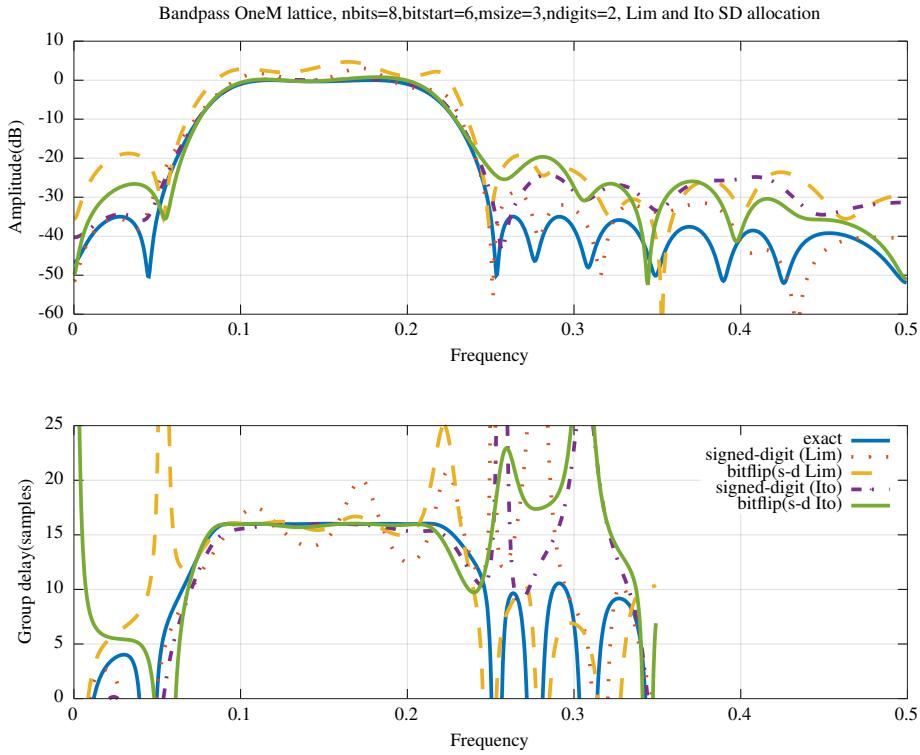

Figure 13.5: Amplitude and group-delay responses of a band-pass filter synthesised as a one-multiplier lattice filter with exact coefficients, 8-bit 2-signed-digit coefficients allocated with Lim's algorithm, 8-bit 2-signed-digit coefficients allocated with Lim's algorithm and optimised with the bit-flipping algorithm, 8-bit 2-signed-digit coefficients allocated with Ito's algorithm and 8-bit 2-signed-digit coefficients allocated with Ito's algorithm and optimised with the bit-flipping algorithm

Band-pass Schur one-multiplier	Cost

          3,       2,       0,       1, ...
          2 ]/128;
```

A total of 29 adders is required to implement these rounded coefficients.

The *bitflip* optimised 8-bit, 2-signed-digit, one-multiplier lattice bandpass filter coefficients are:

```
k_bfsd = [ 0,      96,      0,      60, ...
            0,      48,      0,      48, ...
            0,      40,      0,      32, ...
            0,      20,      0,      12, ...
            0,       5,      0,       2 ]/128;
```

```
c_bfsd = [ 10,      1,      -40,     -80, ...
            -33,     15,      30,      24, ...
             6,     -12,      -7,      -1, ...
            -2,      -7,      -5,       0, ...
            0,       1,       0,       1, ...
            1 ]/128;
```

A total of 20 adders is required to implement these signed-digit coefficients.

13.4 Bit-flipping search for the signed-digit coefficients of a one-multiplier parallel-allpass lattice bandpass IIR filter

The Octave script *bitflip_schurOneMPAlattice_bandpass_test.m* applies the bit-flipping algorithm to the example bandpass filter implemented as a Schur parallel-allpass one-multiplier lattice filter. Note that, in this example, the one-multiplier state scaling coefficients are not truncated. The IIR filter in Section 13.3 has a denominator polynomial decimated with $R = 2$. The initial IIR

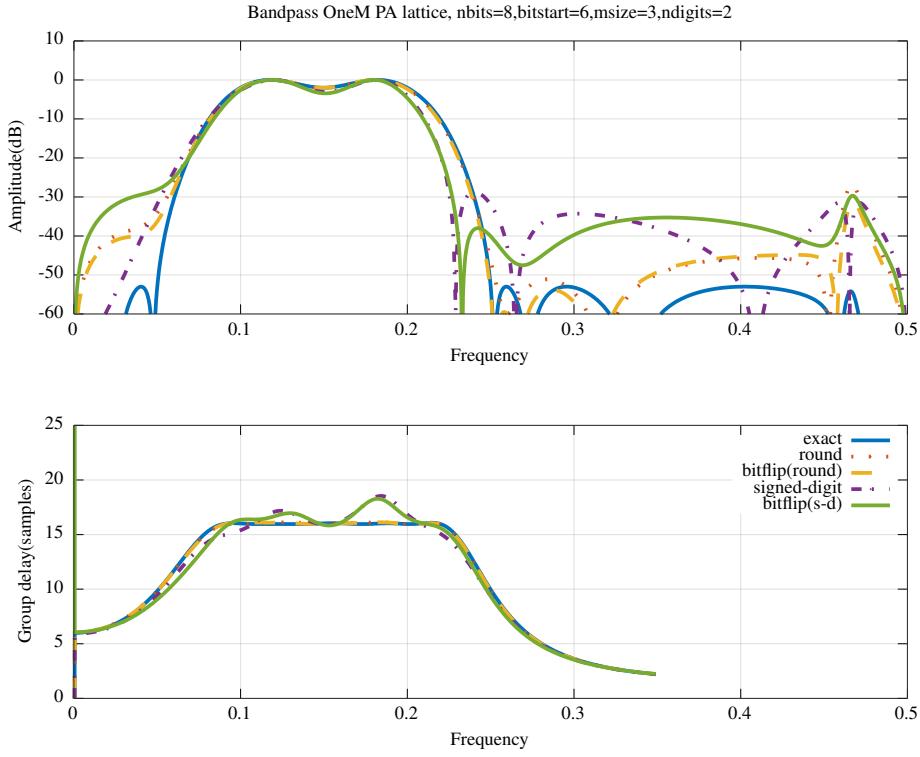

Figure 13.6: Amplitude and group-delay responses of a band-pass filter synthesised as a parallel-allpass one-multiplier lattice filter with exact coefficients, 8-bit rounded coefficients, 8-bit rounded coefficients optimised with the bit-flipping algorithm, 8-bit 2-signed-digit coefficients and 8-bit 2-signed-digit coefficients optimised with the bit-flipping algorithm

filter in this example is that designed by the Octave script *schurOneMPAlattice_socp_slb_bandpass_test.m* with the same filter order and frequency bands but different band weights and amplitude specifications, $d_{Bap} = 2$ and $d_{Bas} = 53$.

The filter responses with exact coefficients, 8-bit rounded coefficients, 8-bit rounded coefficients optimised with the bit-flipping algorithm, 8-bit 2-signed-digit coefficients and 8-bit 2-signed-digit coefficients optimised with the bit-flipping algorithm are shown in Figure 13.6. The filter corresponding passband responses are shown in Figure 13.7.

The filter responses for the signed-digit coefficients with 2-signed-digits, 2-signed-digits allocated with Lim's algorithm and 2-signed-digits allocated with Ito's algorithm are shown in Figure 13.8. The corresponding pass-band responses are shown in Figure 13.9.

Table 13.4 compares the cost result for each test.

Band-pass Schur parallel-allpass one-multiplier	Cost

             72,      -14,     -18,       55, ...
            -40,      19 ]/128;
```

```
A2k_bf = [      -57,      106,       7,      -42, ...
             70,      -25,     -23,       56, ...
            -36,      21 ]/128;
```

A total of 31 adders is required to implement these rounded coefficients.

The *bitflip* optimised 8-bit, 2-signed-digit, parallel-allpass one-multiplier lattice bandpass filter coefficients are:

```
A1k_bfsd = [      -96,      112,       8,      -48, ...
               72,      -14,     -18,       56, ...
              -40,      16 ]/128;
```

```
A2k_bfsd = [      -56,      112,       10,      -40, ...
               72,      -24,     -24,       56, ...
              -36,      20 ]/128;
```

A total of 18 adders is required to implement these signed-digit coefficients.

13.5 Bit-flipping search for the signed-digit coefficients of a minimum-phase band-pass FIR filter

Section 8.2.11 shows the design of a minimum-phase FIR bandpass filter with an amplitude response that is similar to that of the IIR examples above. A minimum-phase FIR filter has all zeros within the unit circle so that the filter polynomial has a Schur

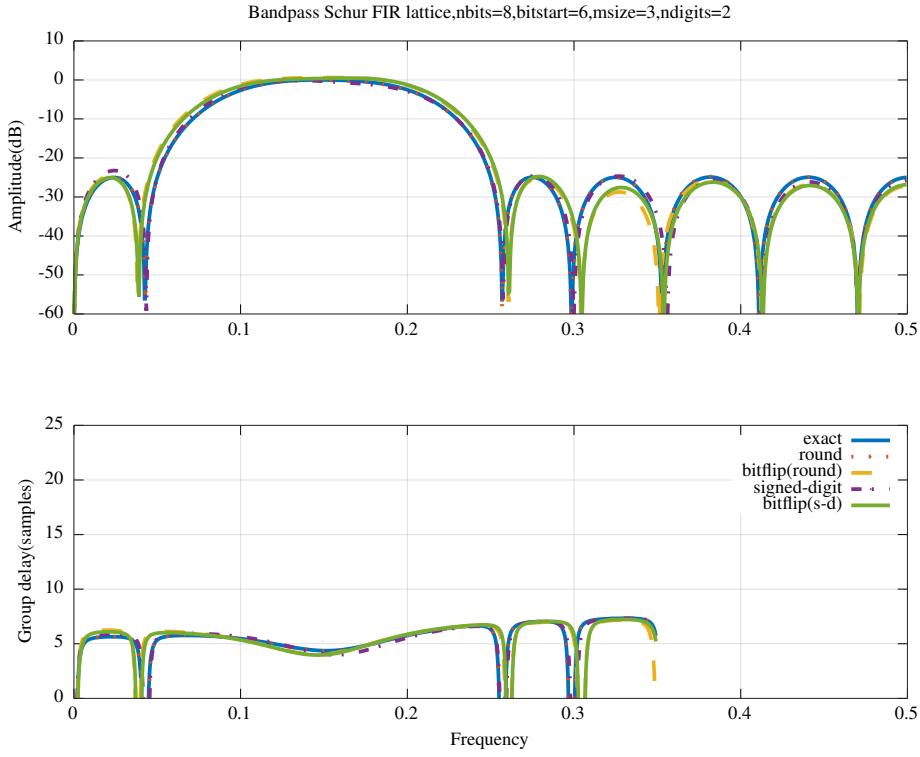

Figure 13.10: Amplitude and group-delay responses of a minimum-phase band-pass filter synthesised as a Schur FIR lattice filter with exact coefficients, 8-bit rounded coefficients, 8-bit rounded coefficients optimised with the bit-flipping algorithm, 8-bit 2-signed-digit coefficients and 8-bit 2-signed-digit coefficients optimised with the bit-flipping algorithm

decomposition. The filter is not linear phase and does not have a flat group delay response. The FIR Schur lattice has two real multipliers for each reflection coefficient [174].

The Octave script, *bitflip_schurFIRlattice_bandpass_test.m* implements the band-pass filter as a minimum-phase Schur FIR lattice filter. In contrast to the previous examples in this chapter, the cost function does not include the group-delay error. As for the Schur one-multiplier lattice IIR filter example, the FIR state scaling coefficients are not truncated. The initial bandpass Schur lattice FIR filter polynomial is that calculated by the Octave script *iir_sqp_slb_fir_17_bandpass_test.m*:

```
b0 = [ 0.0920209477, 0.1200456229, 0.0238698802, -0.1608522791, ...
-0.2457451579, -0.1127458202, 0.1191739637, 0.2218613695, ...
0.1246356125, -0.0268745986, -0.0766798541, -0.0325005729, ...
0.0009004091, -0.0151564755, -0.0332760730, -0.0216108491, ...
0.0235001427 ]';
```

The Schur FIR lattice multiplier coefficients of the initial filter are

```
k_ex = [ 0.4593466811, 0.0207755511, -0.4543038955, -0.5752634543, ...
-0.3661751825, 0.1513717747, 0.4876634116, 0.4458838158, ...
0.0642635216, -0.3825130725, -0.5970105299, -0.7283202009, ...
-0.8093612951, 0.6805119912, -0.6076281309, 0.2553781860 ];
```

The initial FIR filter has order 17, 16 lattice coefficients and 32 multiplies per sample which is similar to the one-multiplier Schur lattice bandpass filter of the previous example.

The initial filter response and the filter responses after coefficient truncation are shown in Figure 13.10.

Table 13.5 compares the cost results for each truncation method.

The *bitflip* optimised 8-bit 2-signed-digit Schur FIR lattice coefficients are:

```
k_bfsd = [ 60, 10, -56, -72, ...
-48, 33, 63, 63, ...
32, -48, -80, -96, ...
-96, 80, -80, 24 ]/128;
```

Band-pass Schur FIR	Cost
Exact	2.7927
8-bit rounded	2.8177
8-bit rounded with bitflipping	2.5710
8-bit 2-signed-digit	2.8214
8-bit 2-signed-digit with bitflipping	2.5595

Table 13.5: Summary of the cost results for the FIR minimum-phase bandpass filter synthesised as a Schur FIR lattice filter with exact coefficients, 8-bit rounded coefficients, 8-bit rounded coefficients optimised with the bit-flipping algorithm, 8-bit 2-signed-digit coefficients and 8-bit 2-signed-digit coefficients optimised with the bit-flipping algorithm

Band-pass direct-form symmetric FIR	Cost
Exact	0.0011
8-bit rounded	0.0015
8-bit rounded with bitflipping	0.0015
8-bit 2-signed-digit	0.0082
8-bit 2-signed-digit with bitflipping	0.0074
8-bit 2-signed-digit(Lim alloc.)	0.0042
8-bit 2-signed-digit(Lim alloc.) with bit-flipping	0.0036
8-bit 2-signed-digit(Ito alloc.)	0.0062
8-bit 2-signed-digit(Ito alloc.) with bit-flipping	0.0047

Table 13.6: Summary of the cost results for the direct-form symmetric FIR bandpass filter with exact coefficients, 8-bit rounded coefficients, 8-bit rounded coefficients optimised with the bit-flipping algorithm, 8-bit 2-signed-digit coefficients and 8-bit 2-signed-digit coefficients optimised with the bit-flipping algorithm. The signed digits are allocated with 2 digits each, Lim's allocation method with an average of 2-signed-digits each and Ito's allocation method with an average of 2-signed-digits each.

A total of 30 adders is required to implement these signed-digit coefficients.

13.6 Bit-flipping search for the signed-digit coefficients of a direct-form symmetric bandpass FIR filter

Appendix L.2 shows the design of a direct-form symmetric FIR bandpass filter with an amplitude response that is similar to that of the IIR examples above. The filter is linear phase and consequently has a flat group delay response. The Octave script *bitflip_directFIRsymmetric_bandpass_test.m* uses the bit-flipping algorithm to optimise the coefficients when truncated to 8-bit integers. The initial filter polynomial is that designed by the Octave script *directFIRsymmetric_slb_bandpass_test.m*. The distinct initial coefficients are:

```
hM_ex = [ -0.0004538174, -0.0114029873, -0.0194431345, -0.0069796479, ...
    0.0215771882, 0.0348545408, 0.0158541332, -0.0033225166, ...
    0.0154055974, 0.0414424100, -0.0021970758, -0.1162784301, ...
    -0.1760013118, -0.0669604509, 0.1451751014, 0.2540400868 ];
```

The filter order is 30 giving a filter delay of 15 samples. The symmetric direct-form implementation requires 16 multipliers. The initial filter response and the filter responses after coefficient truncation are shown in Figure 13.11. The bit-flipping algorithm does not improve the response obtained with 8-bit rounded coefficients.

The filter responses for the signed-digit coefficients with 2-signed-digits, 2-signed-digits allocated with Lim's algorithm and 2-signed-digits allocated with Ito's algorithm are shown in Figure 13.12.

Table 13.6 compares the cost results for each truncation method.

The *bitflip* optimised 8-bit 2-signed-digits (allocated with Lim's algorithm) direct-form symmetric filter coefficients are:

```
hM_bfsdl = [ 0, -3, -5, 0, ...
    6, 8, 3, -1, ...
    4, 11, 0, -30, ...
    -44, -17, 37, 64 ]/256;
```

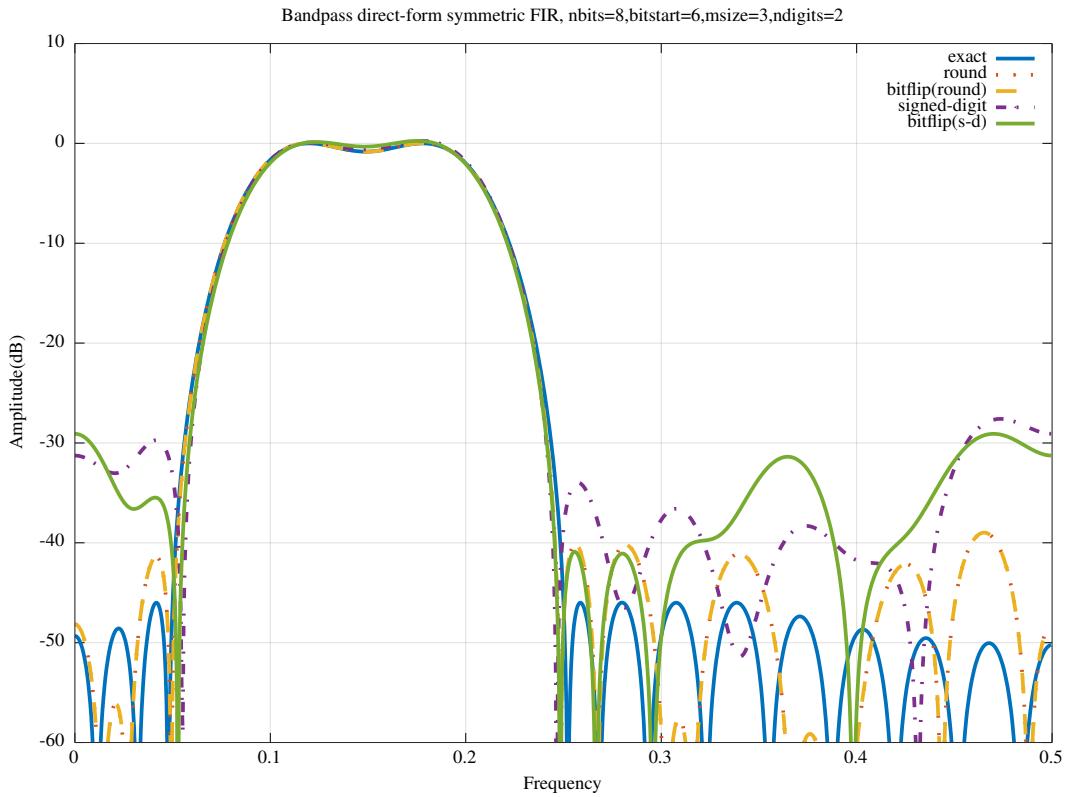

Figure 13.11: Amplitude and group-delay responses of a direct-form symmetric FIR band-pass filter with exact coefficients, 8-bit rounded coefficients, 8-bit rounded coefficients optimised with the bit-flipping algorithm, 8-bit 2-signed-digit coefficients and 8-bit 2-signed-digit coefficients optimised with the bit-flipping algorithm

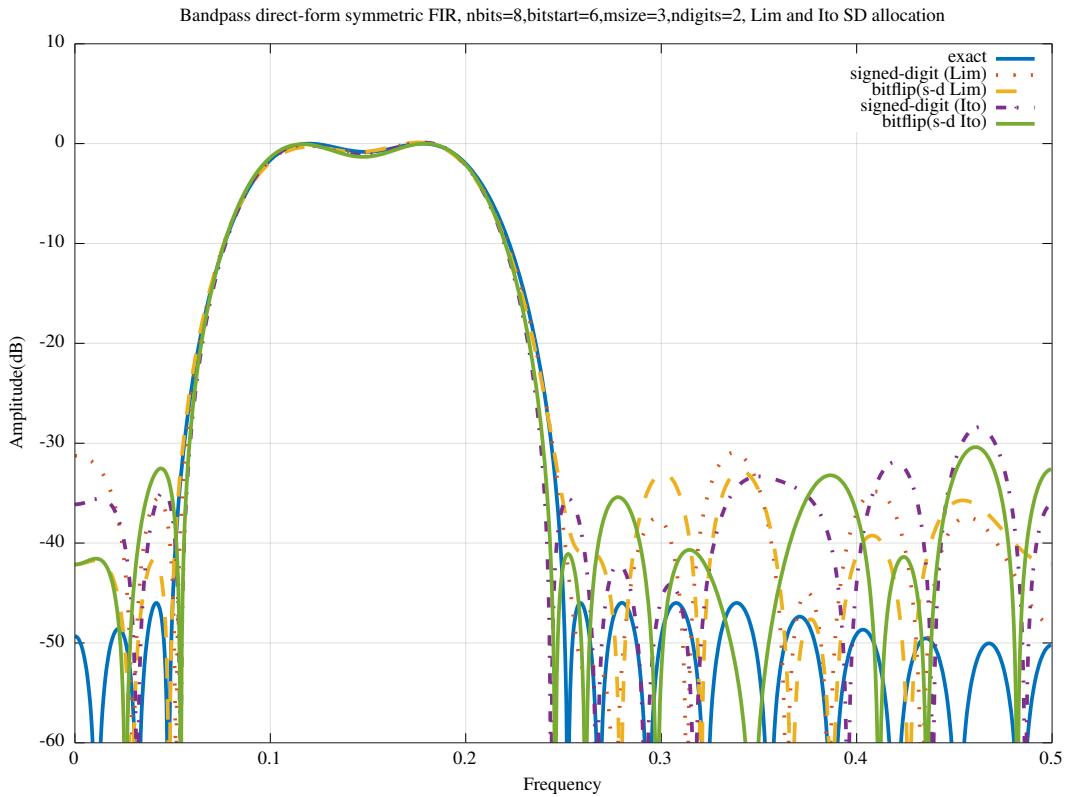

Figure 13.12: Amplitude and group-delay responses of a direct-form symmetric FIR band-pass filter with exact coefficients, 8-bit 2-signed-digit coefficients allocated with Lim's algorithm, 8-bit 2-signed-digit coefficients allocated with Lim's algorithm and optimised with the bit-flipping algorithm, 8-bit 2-signed-digit coefficients allocated with Ito's algorithm and 8-bit 2-signed-digit coefficients allocated with Ito's algorithm and optimised with the bit-flipping algorithm

The coefficients are scaled to make full use of the 8-bit range. A total of 12 adders is required to implement these signed-digit coefficients.

The *bitflip* optimised 8-bit rounded direct-form symmetric FIR coefficients are:

```
hM_bf = [ 0, -3, -5, -2, ...
           6,  9,  4, -1, ...
           4, 11, -1, -30, ...
          -45, -17, 37, 65 ]/256;
```

A total of 14 adders is required to implement these coefficient multiplications in the direct-form symmetric FIR filter structure and 27 adders are required to implement the coefficient multiplications in the transposed (pipelined) direct-form FIR filter structure.

Chapter 14

***Branch-and-bound* search for signed-digit coefficients**

Given the K coefficients, x_k , of a filter, an exhaustive search of the upper and lower bounds on the integer or signed-digit approximations to these coefficients would require $\mathcal{O}(2^K)$ comparisons of the corresponding filter approximation error. *Branch-and-bound* [5], [134, p.627] is a heuristic for reducing the number of branches searched in a binary decision tree. At each branch of the binary tree the solution is compared to the estimated lower bounds on the cost of the full path proceeding from that branch. If the cost of that full path is greater than that of the best full path found so far then further search on that path is abandoned. Figure 14.1 shows a flow diagram of an implementation of the algorithm using a stack. The exact filter coefficients x are approximated by the signed-digit coefficients \bar{x} . Each coefficient, x_k and \bar{x}_k is bounded by the corresponding signed-digit numbers u_k and l_k so that $l_k \leq x_k \leq u_k$ and $l_k \leq \bar{x}_k \leq u_k$. The search for the set of coefficients with minimum cost is “depth-first”, starting at the root of the search tree and fixing successive coefficients. Ito *et al.* [136] recommend choosing, at each branch, the x_k with the greatest difference $u_k - l_k$. The two sub-problems at that branch fix x_k to l_k and u_k . One of the two sub-problems is pushed onto a stack and the other is solved and the cost calculated. I assume that this cost is the least possible for the remaining coefficients on the current branch. If the cost of the current sub-problem is greater than the current minimum cost then the current branch is abandoned and a new sub-problem is popped off the problem stack. Otherwise, if the search has reached the maximum depth of the tree then the current solution is a new signed-digit minimum cost solution. If the current cost is less than the minimum cost and the search has not reached the maximum depth then the search continues with a new branch.

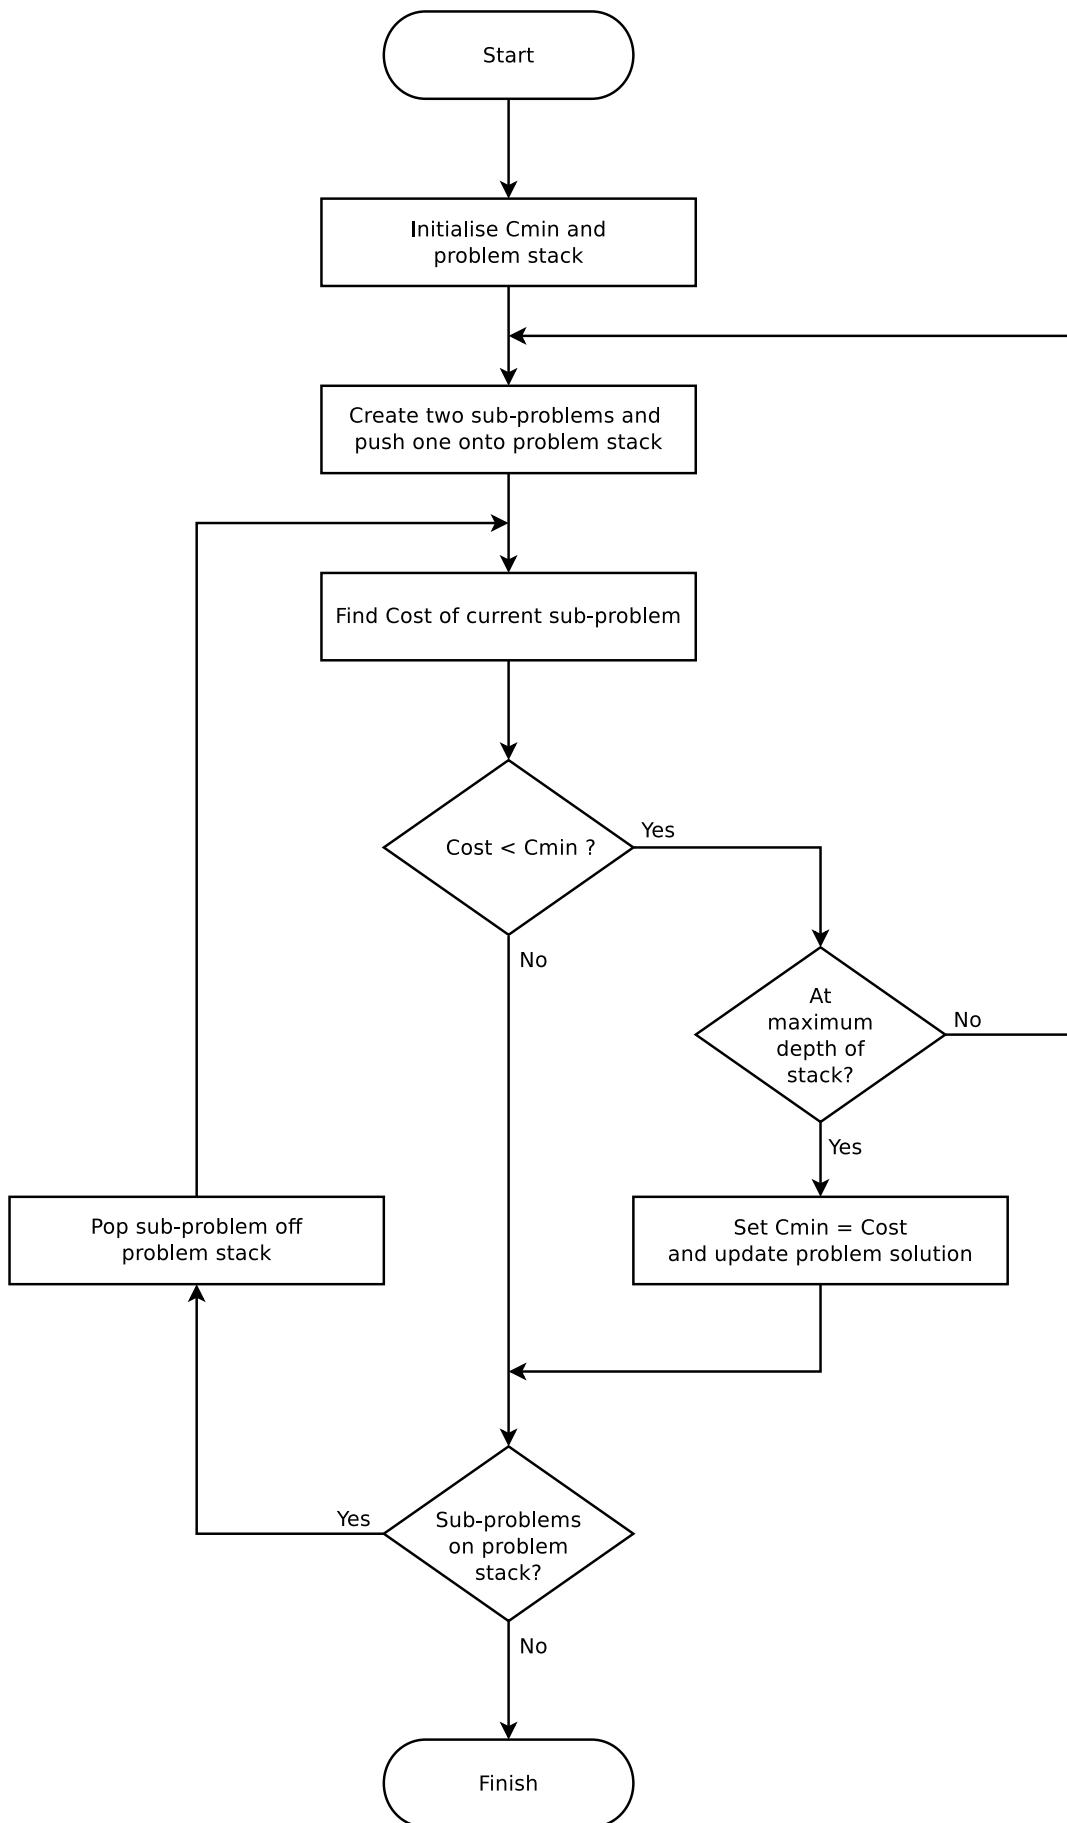

Figure 14.1: The branch-and-bound tree search algorithm.

14.1 Branch-and-bound search for the 8-bit 3-signed-digit coefficients of a direct-form symmetric bandpass FIR filter

The Octave script `branch_bound_directFIRsymmetric_bandpass_8_nbits_test.m` uses the branch-and-bound algorithm to optimise the 8-bit 3-signed-digit coefficients of a direct-form symmetric FIR bandpass filter.

The initial filter polynomial is that designed by the Octave script `directFIRsymmetric_slb_bandpass_test.m`.

```
hM1 = [ -0.0058181010, 0.0017787857, -0.0047084625, -0.0143846688, ...
-0.0077550125, 0.0219788564, 0.0432578789, 0.0247317110, ...
-0.0077853817, -0.0010276677, 0.0304650309, 0.0009925325, ...
-0.1110651112, -0.1806101683, -0.0725659905, 0.1536437055, ...
0.2719559562 ]';
```

The filter specification is:

```
nbits=8 % Coefficient bits
ndigits=3 % Nominal average coefficient signed-digits
escale=2 % Coefficient scaling for full range
tol=0.0001 % Tolerance on coefficient. update
maxiter=400 % iteration limit
fapl=0.1 % Amplitude pass band lower edge
fapu=0.2 % Amplitude pass band upper edge
Wap=1 % Amplitude pass band weight
fasl=0.05 % Amplitude stop band lower edge
fasu=0.25 % Amplitude stop band upper edge
Wasl=5 % Amplitude lower stop band weight
Wasu=10 % Amplitude upper stop band weight
```

The initial filter response and the filter responses after coefficient truncation to 8-bit 3-signed-digits and branch-and-bound search are shown in Figure 14.2. Table 14.1 compares the cost results.

The *branch-and-bound* optimised 8-bit 2-signed-digits direct-form symmetric filter coefficients are:

```
hM_min = [ -1, 0, -2, -4, ...
-2, 5, 11, 6, ...
-1, 0, 8, 1, ...
-28, -47, -19, 39, ...
70 ]'/256;
```

The coefficients are scaled to make full use of the 8-bit range. A total of 13 adders is required to implement these signed-digit coefficient multiplications.

Band-pass direct-form symmetric FIR	Cost	Signed-digits	Additions
Exact	0.00133		
8-bit 3-signed-digit	0.00141	27	13
8-bit 3-signed-digit(branch-and-bound)	0.00127	28	13

Table 14.1: Summary of the cost results for the direct-form symmetric FIR bandpass filter with exact coefficients, 8-bit 3-signed-digit coefficients and 8-bit 3-signed-digit coefficients optimised with the branch-and-bound algorithm.

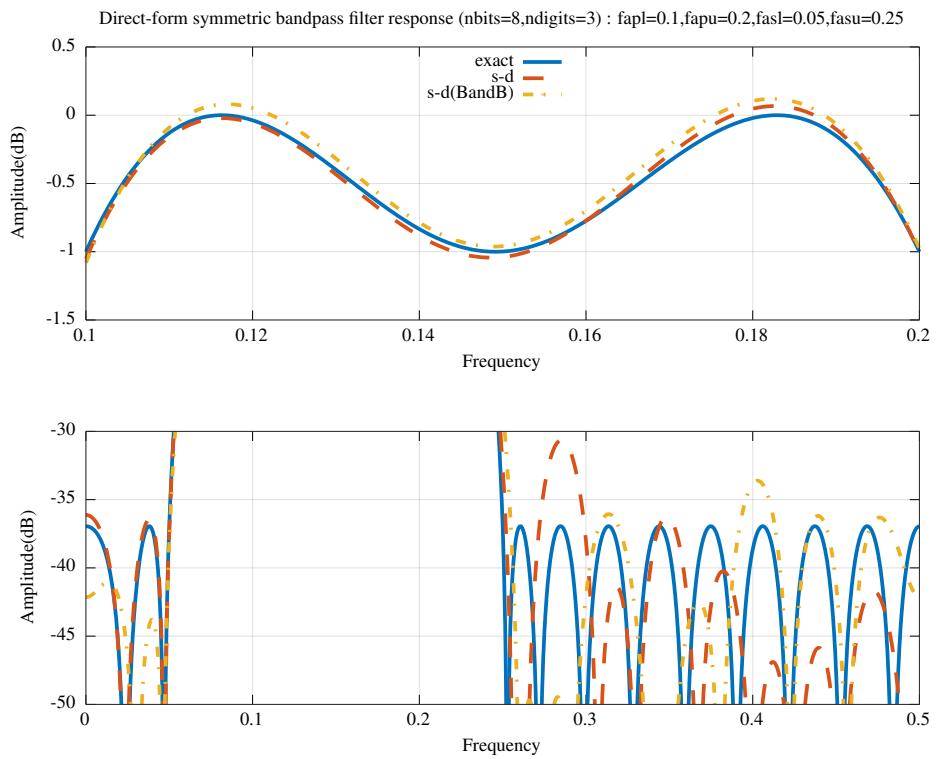

Figure 14.2: Amplitude responses of a direct-form symmetric FIR band-pass filter with exact coefficients, 8-bit 3-signed-digit coefficients and 8-bit 3-signed-digit coefficients optimised with the branch-and-bound algorithm

14.2 Branch-and-bound search for the 8-bit 3-signed-digit coefficients of a lattice band-pass IIR filter

The Octave script `branch_bound_schurOneMlattice_bandpass_8_nbites_test.m` uses the branch-and-bound heuristic to optimise the response of the SQP optimised band-pass Schur one-multiplier lattice filter of Section 10.3.3 with coefficients truncated to 8 bits and 3 signed-digits. The filter specification is:

```
nbits=8 % Coefficient bits
ndigits=3 % Nominal average coefficient signed-digits
tol=0.0001 % Tolerance on coefficient. update
maxiter=400 % SQP iteration limit
npoints=250 % Frequency points across the band
length(c0)=21 % Num. tap coefficients
sum(k0~=0)=10 % Num. non-zero all-pass coef.s
dmax=0.250000 % Constraint on norm of coefficient SQP step size
rho=0.992188 % Constraint on allpass coefficients
fapl=0.1 % Amplitude pass band lower edge
fapu=0.2 % Amplitude pass band upper edge
Wap=1 % Amplitude pass band weight
ftpl=0.09 % Delay pass band lower edge
ftpu=0.21 % Delay pass band upper edge
tp=16 % Nominal passband filter group delay
Wtp=10 % Delay pass band weight
fasl=0.05 % Amplitude stop band lower edge
fasu=0.25 % Amplitude stop band upper edge
Wasl=10000 % Amplitude lower stop band weight
Wasu=10000000 % Amplitude upper stop band weight
```

The 31 non-zero 8-bit 3-signed-digit one-multiplier lattice coefficients found by the branch-and-bound search are:

```
k_min = [      0,      84,      0,      64, ...
            0,      44,      0,      54, ...
            0,      38,      0,      32, ...
            0,      20,      0,      13, ...
            0,       5,      0,       2 ] '/128;

c_min = [     18,      -4,     -76,    -123, ...
           -41,      31,     100,      78, ...
            5,     -21,     -20,      -3, ...
           -2,      -9,      -7,       1, ...
            6,       4,      0,       0, ...
            1 ] '/256;
```

The c_{min} tap coefficients have been scaled to make full use of the range of integers available. I assume that the internal filter state scaling is approximated by bit-shifts. The ϵ one-multiplier lattice coefficients are not recalculated since that would require rescaling the c_{min} tap coefficients. Figure 14.3 compares the pass-band responses of the filter with exact coefficients, the initial 8-bit 3-signed-digit coefficients and 8-bit 3-signed-digit coefficients found by branch-and-bound search. Figure 14.4 shows the filter stop-band response and Figure 14.5 shows the filter pass-band group delay response. Table 14.2 compares the cost and number of 8 bit shift-and-add operations required to implement the 31 coefficient multiplications for the initial signed-digit coefficients and the coefficients found by the branch-and-bound search. A further 41 additions are required by the lattice filter structure^a. Although 3 signed-digits are allocated to each coefficient, many of these signed-digits are not used.

^aA one-multiplier lattice filter with order 21 and denominator polynomial coefficients in z^2 would normally require 1 multiplication and 3 additions for each of 10 lattice sections and 21 filter output tap multiplications and additions. In this case 1 of the lattice filter coefficients and 7 of the tap coefficients are zero. See Figure 5.4.

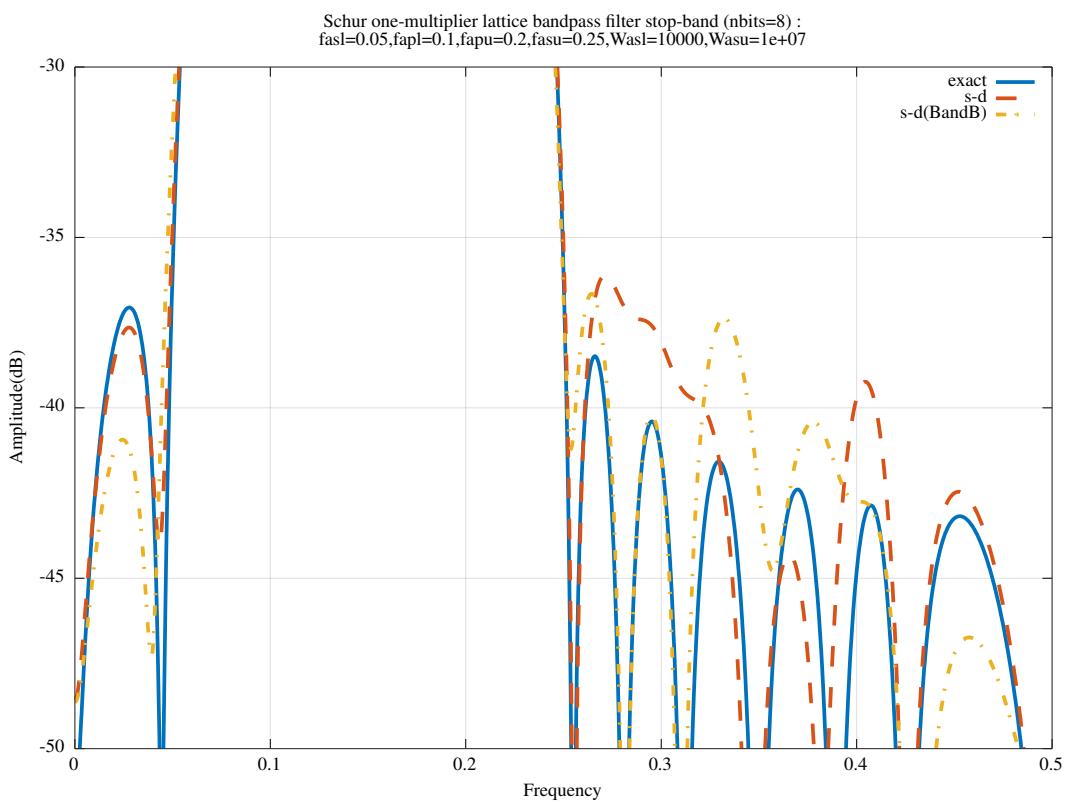

Figure 14.4: Comparison of the stop-band amplitude responses for a Schur one-multiplier lattice bandpass filter with 8-bit 3-signed-digit coefficients found by branch-and-bound search

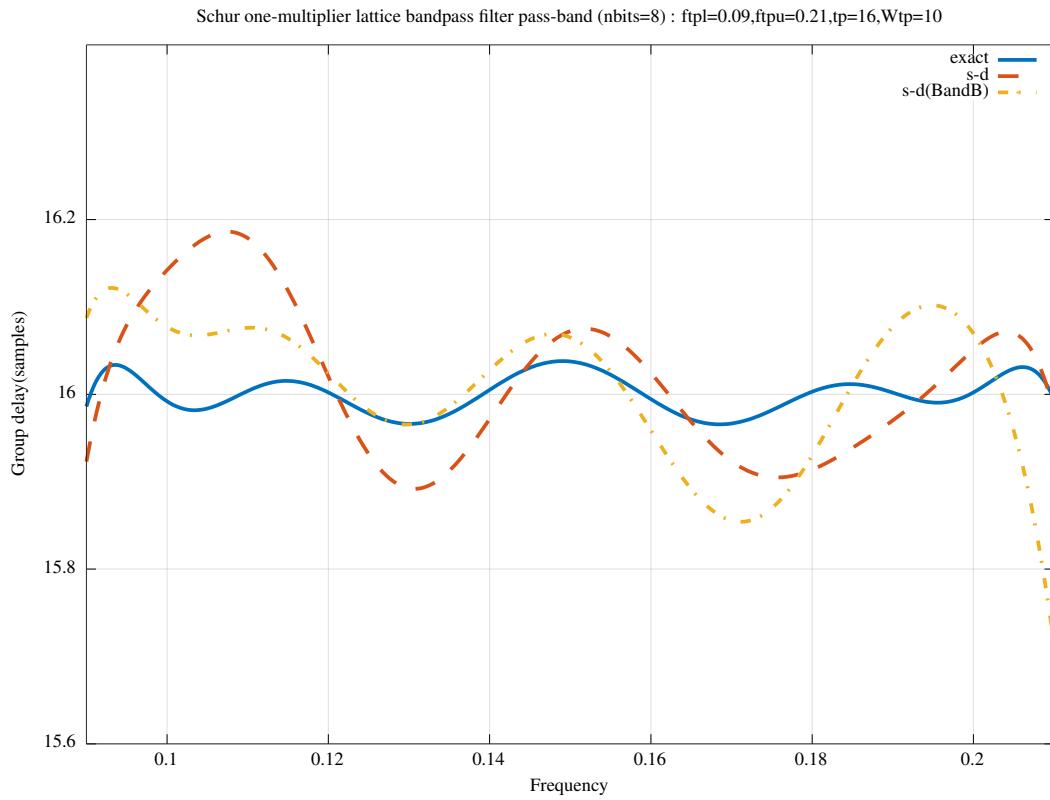

Figure 14.5: Comparison of the pass-band group delay responses for a Schur one-multiplier lattice bandpass filter with 8-bit 3-signed-digit coefficients found by branch-and-bound search

	Cost	Signed-digits	Additions
Exact	0.0521		
8-bit 3-signed-digit	0.2202	64	34
8-bit 3-signed-digit(branch-and-bound)	0.1651	61	32

Table 14.2: Comparison of the cost and number of additions required to implement the coefficient multiplications for a Schur one-multiplier lattice bandpass filter with 8-bit 3-signed-digit coefficients found by branch-and-bound search

14.3 Branch-and-bound search for the 10-bit 3-signed-digit coefficients of a lattice band-pass IIR filter

The Octave script `branch_bound_schurOneMlattice_bandpass_10_nbites_test.m` uses the branch-and-bound heuristic to optimise the response of the band-pass Schur one-multiplier lattice filter of Section 10.3.3. The filter specification is:

```

nbits=10 % Coefficient bits
ndigits=3 % Nominal average coefficient signed-digits
tol=0.0001 % Tolerance on coefficient update
ctol=0.0001 % Tolerance on constraints
maxiter=400 % SQP iteration limit
npoints=250 % Frequency points across the band
length(c0)=21 % Num. tap coefficients
sum(k0~=0)=10 % Num. non-zero all-pass coef.s
dmax=0.250000 % Constraint on norm of coefficient SQP step size
rho=0.998047 % Constraint on allpass coefficients
fapl=0.1 % Amplitude pass band lower edge
fapu=0.2 % Amplitude pass band upper edge
dBap=2 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
ftpl=0.09 % Delay pass band lower edge
ftpu=0.21 % Delay pass band upper edge
tp=16 % Nominal passband filter group delay
tpr=0.2 % Delay pass band peak-to-peak ripple
Wtp=5 % Delay pass band weight
fasl=0.05 % Amplitude stop band lower edge
fasu=0.25 % Amplitude stop band upper edge
dBas=33 % Amplitude stop band peak-to-peak ripple
Wasl=500000 % Amplitude lower stop band weight
Wasu=1000000 % Amplitude upper stop band weight

```

The filter coefficients are truncated to 10 bits with an average of 3 signed-digits allocated to each coefficient. The number of signed-digits allocated to each coefficient is determined by the heuristic of *Ito et al.* as shown in Section 11.2. The average number of non-zero signed-digits per coefficient is close to 2. The tap coefficients are scaled to make full use of the range of integers available. I assume that the internal filter state scaling is approximated by bit-shifts.

At each branch the script fixes the coefficient with the largest difference between upper and lower 3 signed-digit approximations to the floating-point value. For each sub-problem the coefficients “higher-up-the-tree” are fixed and the remaining free coefficients are SQP PCLS optimised with the filter specification given above. For this example the branch-and-bound search makes thousands of branches and requires several hours CPU time on my PC.

The filter coefficients found by the branch-and-bound search are:

```

k_min = [      0,      328,      0,      256, ...
            0,      176,      0,      216, ...
            0,      149,      0,      128, ...
            0,       78,      0,       54, ...
            0,       19,      0,        8 ]'/512;

c_min = [      72,      -32,     -336,     -480, ...
           -129,      160,      416,      280, ...
            -4,      -94,      -80,       -8, ...
            -8,      -32,      -20,        9, ...
           28,       16,        1,       -2, ...
            2 ]'/1024;

```

Figure 14.6 compares the pass-band responses of the filter with exact, 10-bit signed-digit coefficients allocated with the algorithm of *Ito et al.* and 10-bit signed-digits allocated with the algorithm of *Ito et al.* and branch-and-bound search. Figure 14.7 shows the filter stop-band response and Figure 14.8 shows the filter pass-band group delay response. Table 14.3 compares the cost and the number of 10 bit shift-and-add operations required to implement the 31 coefficient multiplications found by the signed-digit allocation heuristic of *Ito et al.* with the branch-and-bound search. A further 51 additions are required by the lattice filter structure. The truncation of the last coefficient is, by necessity, not PCLS optimised so the final set of coefficients may not meet the PCLS specifications.

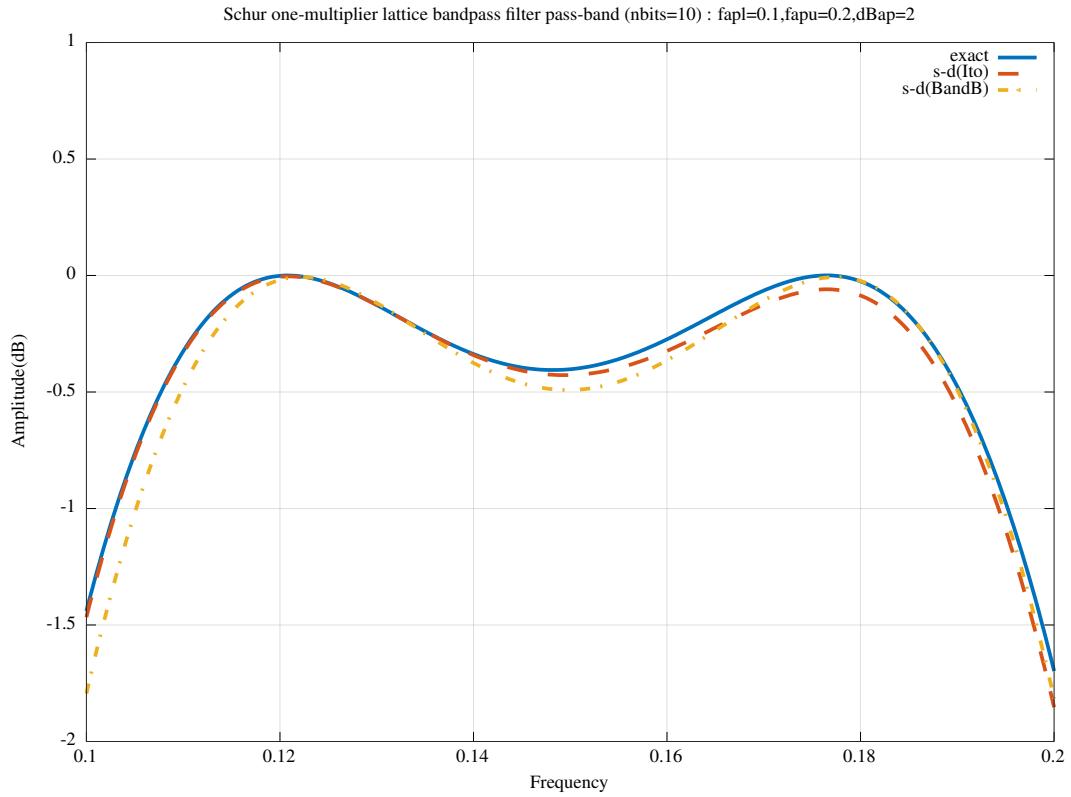

Figure 14.6: Comparison of the pass-band amplitude responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search

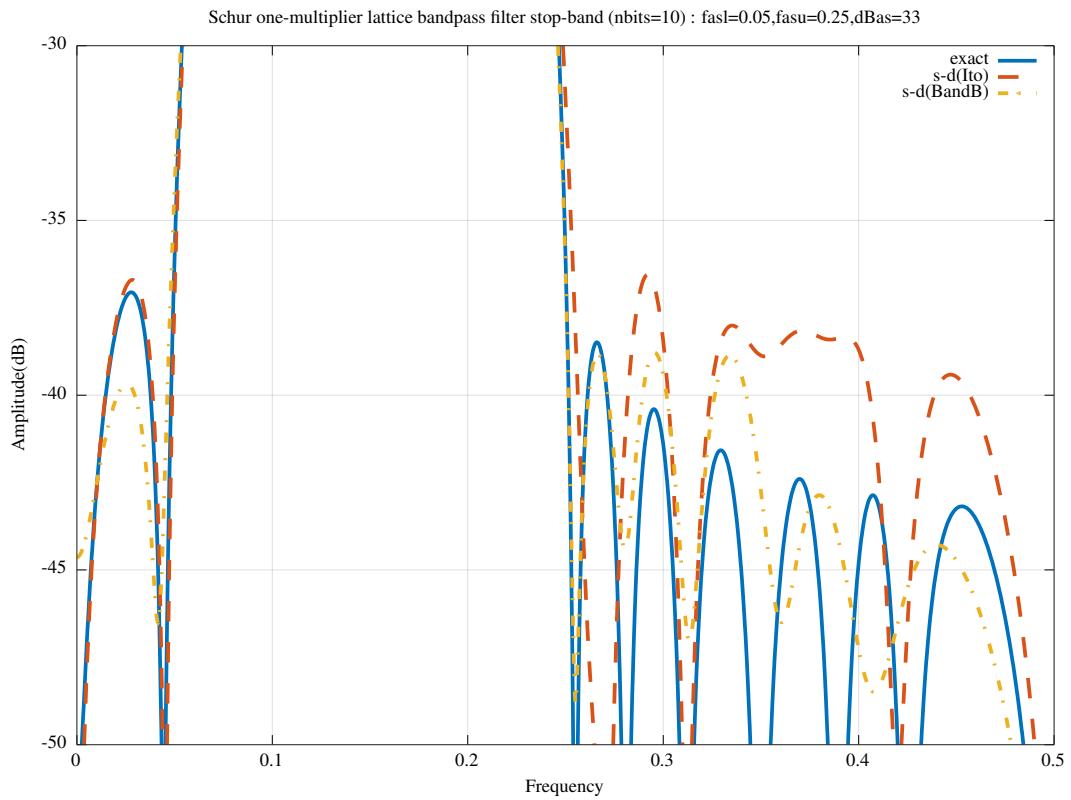

Figure 14.7: Comparison of the stop-band amplitude responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search

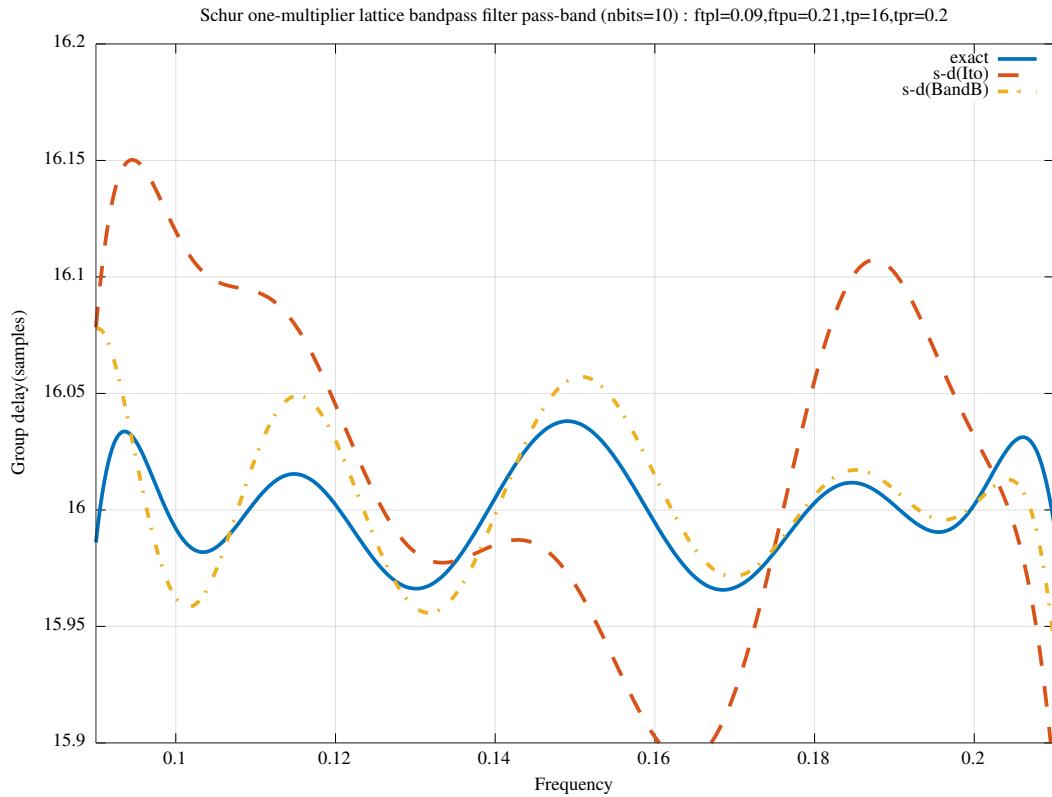

Figure 14.8: Comparison of the pass-band group delay responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search

	Cost	Signed-digits	Shift-and-adds
Exact	0.0158		
10-bit 3-signed-digit(Ito)	0.0596	64	33
10-bit 3-signed-digit(branch-and-bound)	0.0218	62	31

Table 14.3: Comparison of the cost and number of 10-bit shift-and-add operations required to implement the coefficient multiplications for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search

14.4 Branch-and-bound search for the 12-bit 3-signed-digit coefficients of a parallel all-pass lattice low-pass IIR filter

The Octave script `branch_bound_schurOneMPAlattice_lowpass_12_nbites_test.m` performs branch-and-bound search to optimise the response of the parallel Schur one-multiplier all-pass lattice low-pass filter of Section 10.3.6 with 12-bit integer coefficients. The filter specification is:

```

nbits=12 % Coefficient word length
ndigits=3 % Average number of signed digits per coef.
tol=0.0001 % Tolerance on coefficient update vector
ctol=5e-07 % Tolerance on constraints
n=400 % Frequency points across the band
difference=0 % Use difference of all-pass filters
m1=11 % Allpass model filter 1 denominator order
m2=12 % Allpass model filter 2 denominator order
rho=0.992188 % Constraint on allpass coefficients
fap=0.125 % Amplitude pass band edge
dBap=0.2 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
Wat=0 % Amplitude transition band weight
fas=0.25 % Amplitude stop band edge
dBas=56 % amplitude stop band peak-to-peak ripple
Was=10000 % Amplitude stop band weight
ftp=0.175 % Delay pass band edge
td=11.5 % Nominal pass band filter group delay
tdr=0.08 % Delay pass band peak-to-peak ripple
Wtp=0.1 % Delay pass band weight

```

The filter coefficients are truncated to 12 bits allocated with an average of 3 signed-digits by the heuristic of *Ito et al.* as shown in Section 11.2. At each branch the script fixes the coefficient with the largest difference between upper and lower 3 signed-digit approximations to the floating-point value. For each sub-problem the coefficients “higher-up-the-tree” are fixed and the remaining free coefficients are SOCP PCLS optimised with the filter specification given above. In this case there are no filter tap coefficients and the one-multiplier lattice ϵ coefficients can be recalculated. The signed-digit lattice coefficients found by the heuristic of *Ito et al.* are:

```

A1k0_sd = [ 1576,      -176,      -544,      -128, ...
             -128,       501,      -296,       -8, ...
              336,      -327,      112 ]'/2048;

A2k0_sd = [ 800,      -560,      384,      336, ...
             -96,        84,      -412,      368, ...
              8,      -364,      308,     -113 ]'/2048;

```

The signed-digit lattice coefficients found by the branch-and-bound search are:

```

A1k_min = [ 1584,      -184,      -544,      -128, ...
             -128,       488,      -296,        1, ...
              336,      -316,      112 ]'/2048;

A2k_min = [ 784,      -584,      384,      336, ...
             -96,        88,      -404,      368, ...
              4,      -360,      300,     -113 ]'/2048;

```

The signed-digit lattice coefficients found by the branch-and-bound search are implemented with 61 signed-digits and 38 shift-and-add operations.

Figure 14.9 shows the amplitude pass-band response of the filter with 12-bit 3-signed-digit coefficients allocated with the algorithm of *Ito et al.* and branch-and-bound search. Figure 14.10 shows the corresponding filter pass-band group-delay response. Figure 14.11 shows the corresponding filter stop-band amplitude response. Table 14.4 compares the cost and the number of 12 bit shift-and-add operations required to implement the coefficient multiplications found by the signed-digit allocation heuristic of *Ito et al.* with the branch-and-bound search.

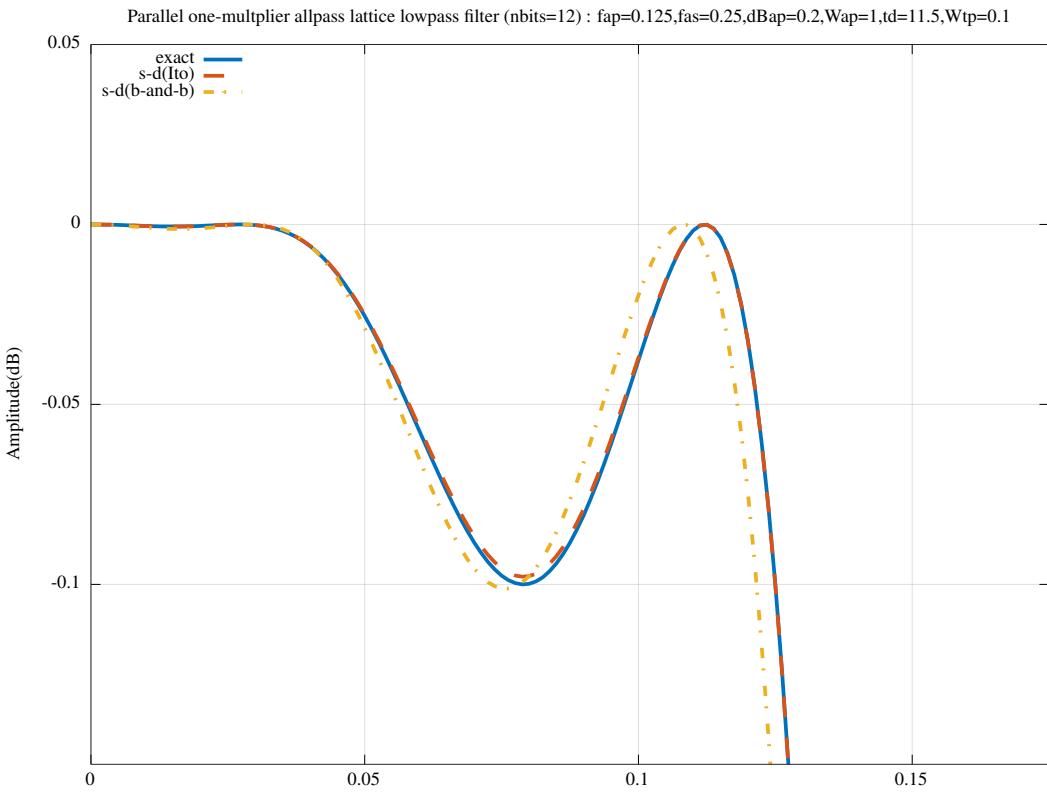

Figure 14.9: Amplitude pass-band response for a parallel Schur one-multiplier all-pass lattice low-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search.

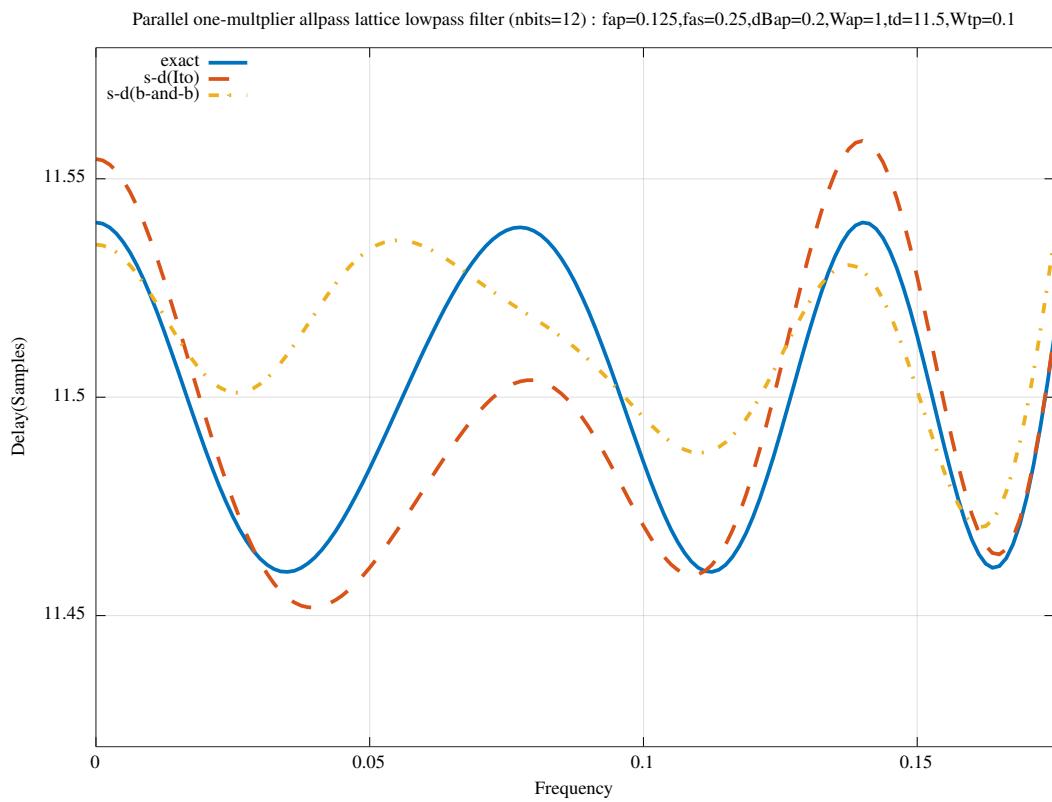

Figure 14.10: Group-delay pass-band response for a parallel Schur one-multiplier all-pass lattice low-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search.

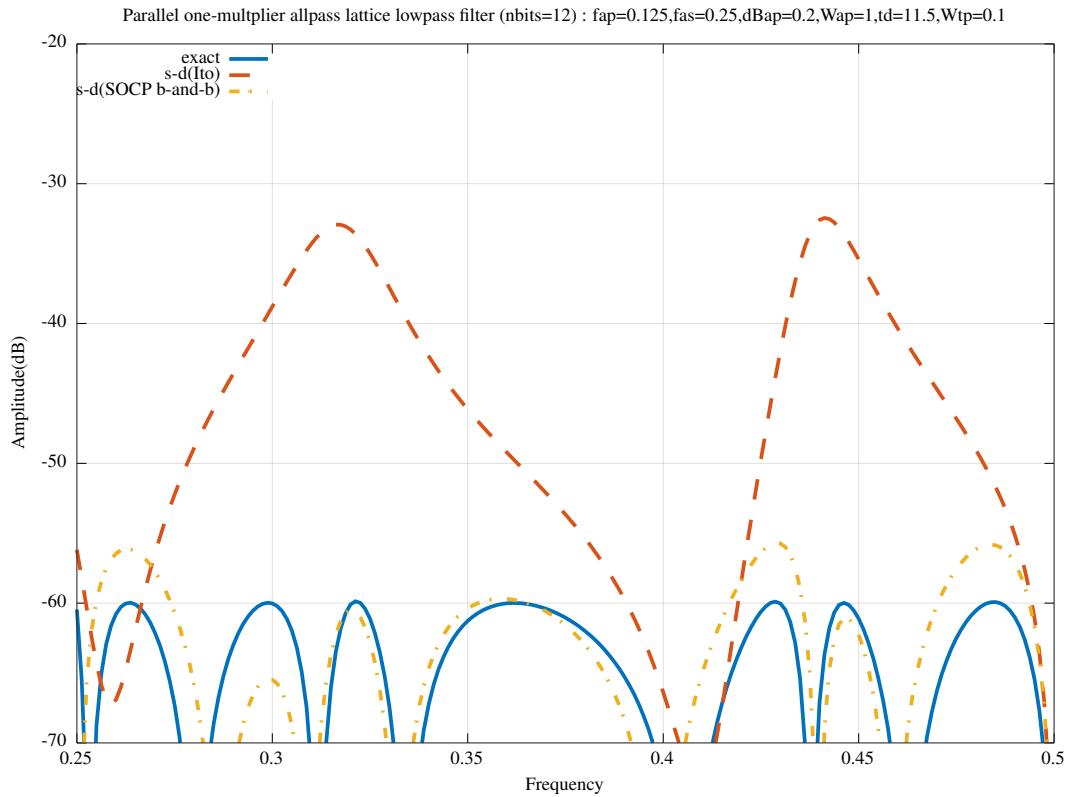

Figure 14.11: Amplitude stop-band response for a parallel Schur one-multiplier all-pass lattice low-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search.

	Cost	Signed-digits	Shift-and-adds
Exact	0.000192		
12-bit 3-signed-digit(Ito)	0.000709	63	40
12-bit 3-signed-digit(SOCP b-and-b)	0.000175	61	38

Table 14.4: Comparison of the cost and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for a parallel Schur one-multiplier all-pass lattice low-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search.

14.5 Branch-and-bound search for the 8-bit 3-signed-digit coefficients of a parallel all-pass lattice IIR elliptic low-pass filter

The Octave script *branch_bound_schurOneMPAlattice_elliptic_lowpass_8_nbits_test.m* performs branch-and-bound search to optimise the response of a parallel Schur one-multiplier all-pass lattice elliptic approximation low-pass filter with 8-bit integer coefficients. The filter specification is:

```
N=5 % Filter order
nbits=8 % Coefficient word length
ndigits=2 % Average number of signed digits per coef.
tol=0.0001 % Tolerance on coefficient update vector
ctol=1e-08 % Tolerance on constraints
n=1000 % Frequency points across the band
difference=0 % Use difference of all-pass filters
rho=0.992188 % Constraint on allpass coefficients
fap=0.04 % Amplitude pass band edge
dBap=0.2 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
Wat=0 % Amplitude transition band weight
fas=0.053 % Amplitude stop band edge
dBas=20 % amplitude stop band peak-to-peak ripple
Was=10 % Amplitude stop band weight
```

The filter coefficients are truncated to 8 bits and 2 signed-digits. At each branch the script fixes the coefficient with the largest difference between upper and lower 2 signed-digit approximations to the floating-point value. For each sub-problem the coefficients “higher-up-the-tree” are fixed and the remaining free coefficients are SOCP PCLS optimised with the filter specification given above.

The 8 bit, 2 signed-digit lattice coefficients are:

```
A1k0_sd = [ -124, 112 ]'/128;
A2k0_sd = [ -124, 127, -96 ]'/128;
```

The signed-digit lattice coefficients found by the branch-and-bound search are:

```
A1k_min = [ -124, 96 ]'/128;
A2k_min = [ -124, 126, -96 ]'/128;
```

The signed-digit lattice coefficients found by the branch-and-bound search are implemented with 10 signed-digits and 5 shift-and-add operations.

Figure 14.12 shows the amplitude response of the filter with 8-bit, 2-signed-digit coefficients and branch-and-bound search. Figure 14.13 shows the filter pass-band amplitude response. Table 14.5 compares the cost and the number of 8 bit shift-and-add operations required to implement the coefficient multiplications found with the branch-and-bound search.

	Cost	Signed-digits	Shift-and-adds
Exact	0.000661		
8-bit 2-signed-digit	0.008154	10	5
8-bit 2-signed-digit(b-and-b)	0.000046	10	5

Table 14.5: Comparison of the cost and number of 8-bit shift-and-add operations required to implement the coefficient multiplications for a parallel Schur one-multiplier all-pass lattice elliptic approximation low-pass filter with 8 bit, 2 signed-digit integer coefficients found by performing branch-and-bound search.

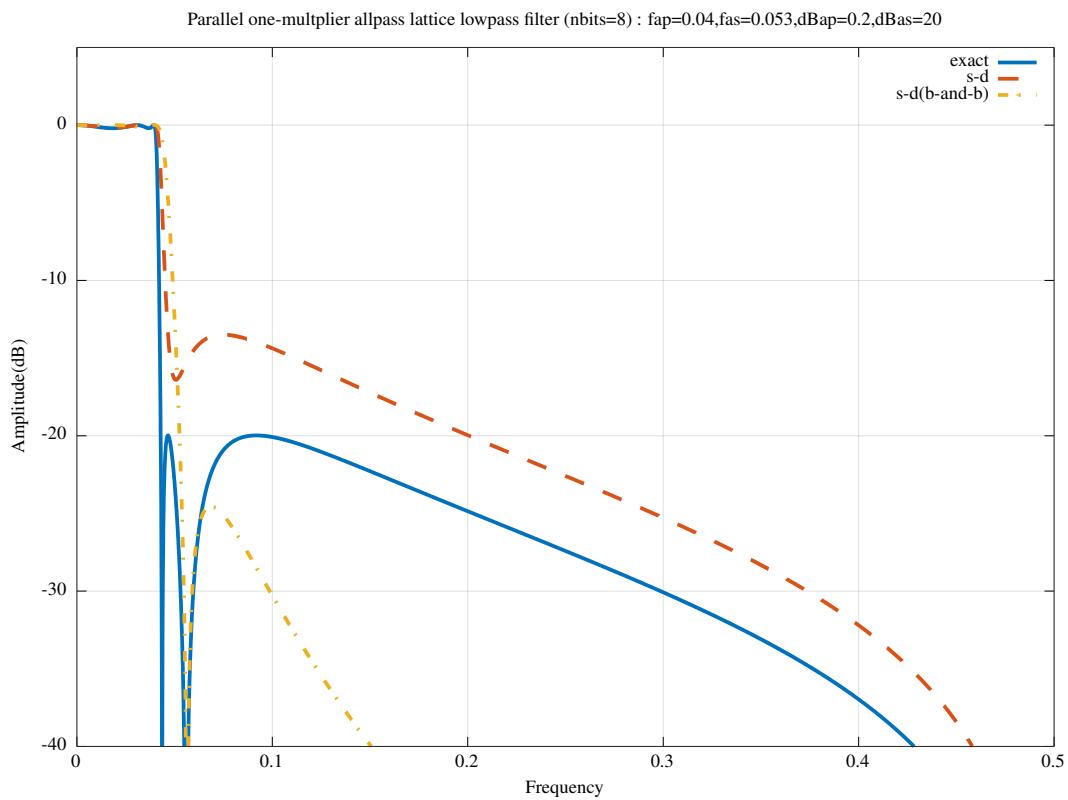

Figure 14.12: Amplitude response for a parallel Schur one-multiplier all-pass lattice elliptic approximation low-pass filter with 8 bit, 2-signed-digits integer coefficients found performing branch-and-bound search.

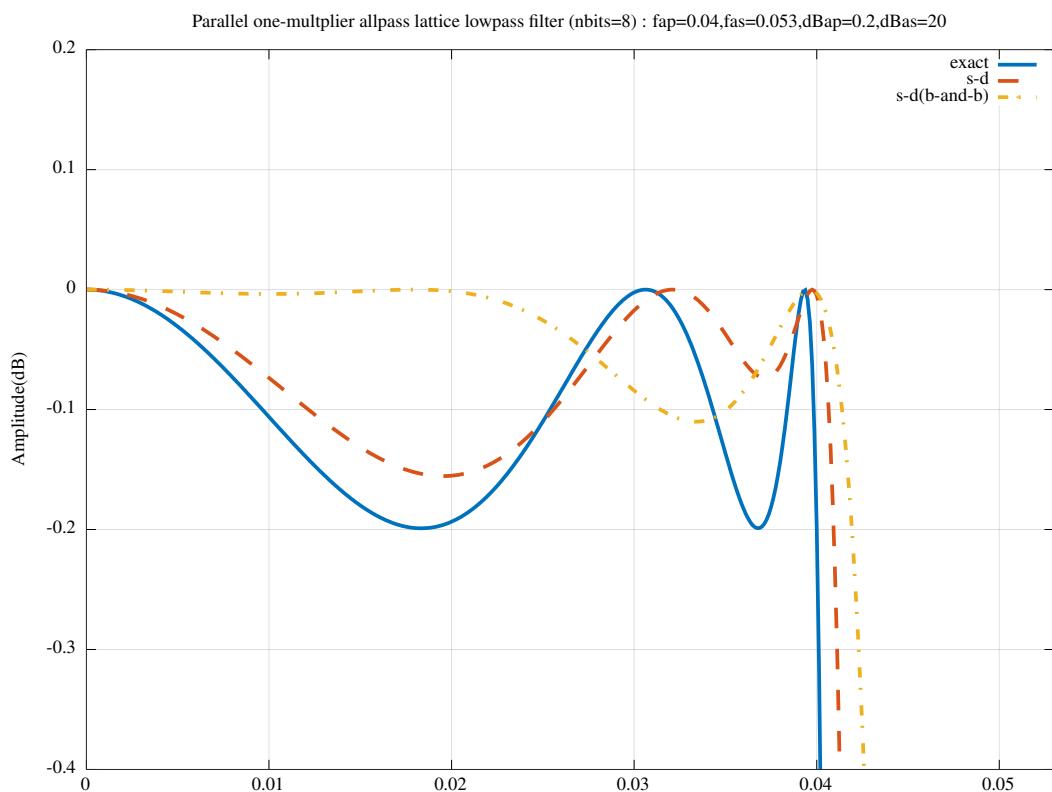

Figure 14.13: Amplitude pass-band response for a parallel Schur one-multiplier all-pass lattice elliptic approximation low-pass filter with 8 bit, 2 signed-digit integer coefficients found by performing branch-and-bound search.

14.6 Branch-and-bound search for the 16-bit 4-signed-digit coefficients of a parallel all-pass lattice IIR elliptic low-pass filter

The Octave script *branch_bound_schurOneMPAlattice_elliptic_lowpass_16_nbis_test.m* performs branch-and-bound search to optimise the response of the parallel Schur one-multiplier all-pass lattice elliptic low-pass filter with 16-bit integer coefficients. The filter specification is:

```
nbits=16 % Coefficient word length
ndigits=4 % Average number of signed digits per coef.
tol=0.0001 % Tolerance on coefficient update vector
ctol=5e-09 % Tolerance on constraints
n=2000 % Frequency points across the band
difference=0 % Use difference of all-pass filters
rho=0.992188 % Constraint on allpass coefficients
fape=0.05 % Extra amplitude weight pass band edge
fap=0.15 % Amplitude pass band edge
dBap=0.04 % Amplitude pass band peak-to-peak ripple
Wape=0 % Extra amplitude pass band weight
Wap=1 % Amplitude pass band weight
Wat=0.0001 % Amplitude transition band weight
fas=0.171 % Amplitude stop band edge
fase=0.271 % Extra amplitude weight stop band edge
dBas=77 % amplitude stop band peak-to-peak ripple
Was=10000000 % Amplitude stop band weight
Wase=0 % Extra amplitude stop band weight
```

The initial parallel all-pass filters are those for the filter designed by the Octave function *ellip(11,0.02,84,2*0.15)*. The filter coefficients are truncated to 16 bits allocated with an average of 4 signed-digits by the heuristic of *Ito et al.* as shown in Section 11.2. The following numbers of signed-digits are allocated to the lattice coefficients:

```
A1k0_allocsd_digits = [ 4, 3, 5, 5, ...
4, 4 ]';
```

```
A2k0_allocsd_digits = [ 3, 3, 5, 5, ...
3 ]';
```

The signed-digit lattice coefficients found by the heuristic of *Ito et al.* are:

```
A1k0_sd = [ -19712, 32384, -25792, 28320, ...
-23520, 11808 ]'/32768;
```

```
A2k0_sd = [ -22528, 30736, -26768, 23872, ...
-11776 ]'/32768;
```

The signed-digit lattice coefficients found by the branch-and-bound search are:

```
A1k_min = [ -19584, 32384, -25760, 28304, ...
-23551, 11840 ]'/32768;
```

```
A2k_min = [ -22528, 30736, -26768, 23904, ...
-11776 ]'/32768;
```

The signed-digit lattice coefficients found by the branch-and-bound search are implemented with 44 signed-digits and 33 shift-and-add operations.

Figure 14.14 shows the amplitude pass-band response of the filter with 16-bit 4-signed-digit coefficients allocated with the algorithm of *Ito et al.* and branch-and-bound search. Figure 14.15 shows the amplitude stop-band response. Table 14.6 compares the cost and the number of 16 bit shift-and-add operations required to implement the coefficient multiplications found by the signed-digit allocation heuristic of *Ito et al.* with the branch-and-bound search.

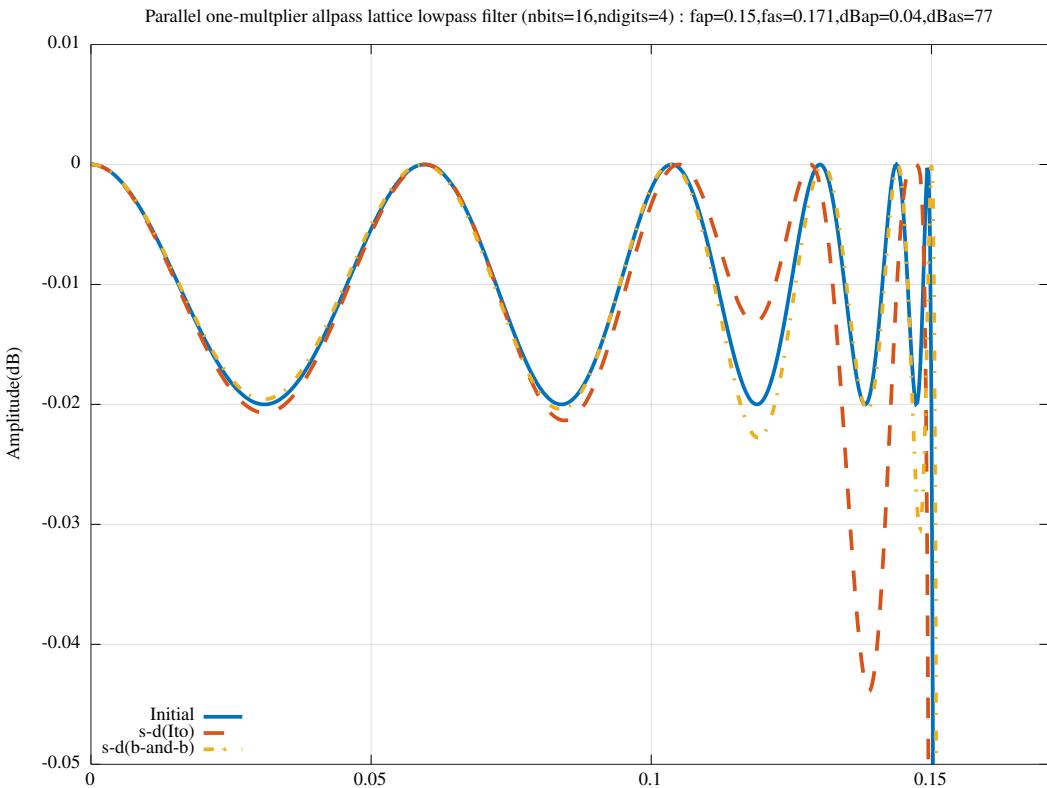

Figure 14.14: Amplitude pass-band response of a parallel Schur one-multiplier all-pass lattice elliptic approximation low-pass filter with 16 bit integer coefficients found by allocating an average of 4-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search.

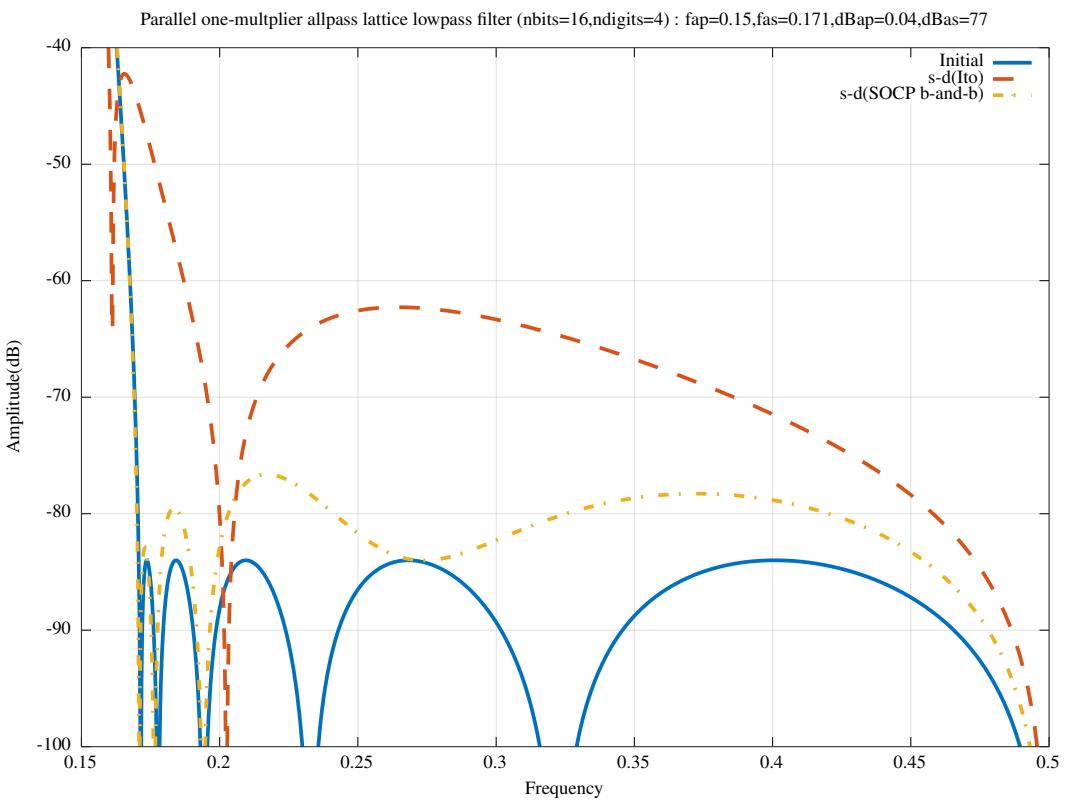

Figure 14.15: Amplitude stop-band response of a parallel Schur one-multiplier all-pass lattice elliptic approximation low-pass filter with 16 bit integer coefficients found by allocating an average of 4-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search.

	Cost	Signed-digits	Shift-and-adds
Initial	7.49e-06		
16-bit 4-signed-digit(Ito)	1.67e-04	44	33
16-bit 4-signed-digit(SOCP b-and-b)	8.25e-06	44	33

Table 14.6: Comparison of the cost and number of 16-bit shift-and-add operations required to implement the coefficient multiplications for a parallel Schur one-multiplier all-pass lattice elliptic approximation low-pass filter with 16 bit integer coefficients found by allocating an average of 4-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search.

14.7 Branch-and-bound search for the 12-bit 3-signed-digit coefficients of a parallel all-pass lattice band-pass IIR filter

The Octave script `branch_bound_schurOneMPAlattice_bandpass_12_nbites_test.m` performs branch-and-bound search to optimise the response of the parallel Schur one-multiplier all-pass lattice band-pass filter of Section 10.3.7 with 12-bit integer coefficients. The filter specification is:

```

use_best_branch_and_bound_found=1
enforce_pccls_constraints_on_final_filter=1
branch_bound_schurOneMPAlattice_bandpass_12_nbites_test_allocsd_Lim=1
branch_bound_schurOneMPAlattice_bandpass_12_nbites_test_allocsd_Ito=0
nbits=12 % Coefficient word length
ndigits=3 % Average number of signed digits per coef.
tol=0.0001 % Tolerance on coefficient update vector
ctol=1e-06 % Tolerance on constraints
n=1000 % Frequency points across the band
difference=1 % Use difference of all-pass filters
m1=10 % Allpass model filter 1 denominator order
m2=10 % Allpass model filter 2 denominator order
rho=0.992188 % Constraint on allpass coefficients
fapl=0.1 % Pass band amplitude response lower edge

td=16.000000 % Pass band nominal group-delay response(samples)
tdr=0.200000 % Pass band group-delay response ripple(samples)
Wtp=1 % Pass band group-delay response weight

```

The filter coefficients are truncated to 12 bits allocated with an average of 3 signed-digits by the heuristic of Lim *et al.* as shown in Section 11.1. At each branch the script fixes the coefficient with the largest difference between upper and lower 3 signed-digit approximations to the floating-point value. For each sub-problem the coefficients “higher-up-the-tree” are fixed and the remaining free coefficients are SOCP PCLS optimised with the filter specification given above.

The signed-digit lattice coefficients found by the heuristic of Lim *et al.* are:

```
A1k0_sd = [ -1570,      1775,       48,      -760, ...
             1158,     -224,        0,      880, ...
            -636,      312 ]'/2048;
```

```
A2k0_sd = [ -905,      1696,       120,      -672, ...
             1116,     -392,      -376,      896, ...
            -580,      320 ]'/2048;
```

The signed-digit lattice coefficients found by the branch-and-bound search are:

```
A1k_min = [ -1564,      1732,       160,      -832, ...
              1287,     -504,        0,      736, ...
             -560,      312 ]'/2048;
```

```

              1250,     -636,      -58,      752, ...
             -540,      320 ]'/2048;
```

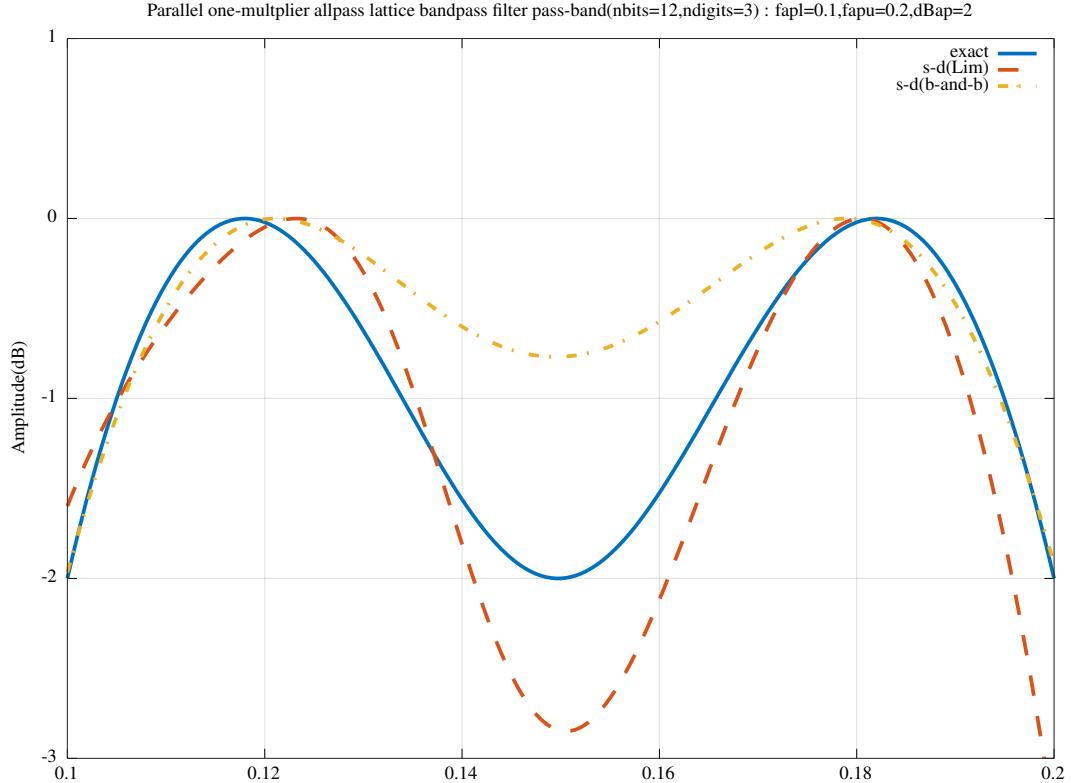

Figure 14.16: Amplitude pass-band response for a parallel Schur one-multiplier all-pass lattice band-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing branch-and-bound search.

The signed-digit lattice coefficients found by the branch-and-bound search are implemented with 59 signed-digits and 40 shift-and-add operations.

Figure 14.16 shows the amplitude pass-band response of the filter with 12-bit 3-signed-digit coefficients allocated with the algorithm of *Lim et al.* and branch-and-bound search. Figure 14.17 shows the corresponding filter pass-band group-delay response. Figure 14.18 shows the corresponding filter stop-band amplitude response. Table 14.7 compares the cost and the number of 12 bit shift-and-add operations required to implement the coefficient multiplications found by the signed-digit allocation heuristic of *Lim et al.* with the branch-and-bound search.

	Cost	Signed-digits	Shift-and-adds
Exact	0.018358		
12-bit 3-signed-digit(Lim)	4.567953	58	39
12-bit 3-signed-digit(SOCP b-and-b)	0.011455	59	40

Table 14.7: Comparison of the cost and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for a parallel Schur one-multiplier all-pass lattice band-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing branch-and-bound search.

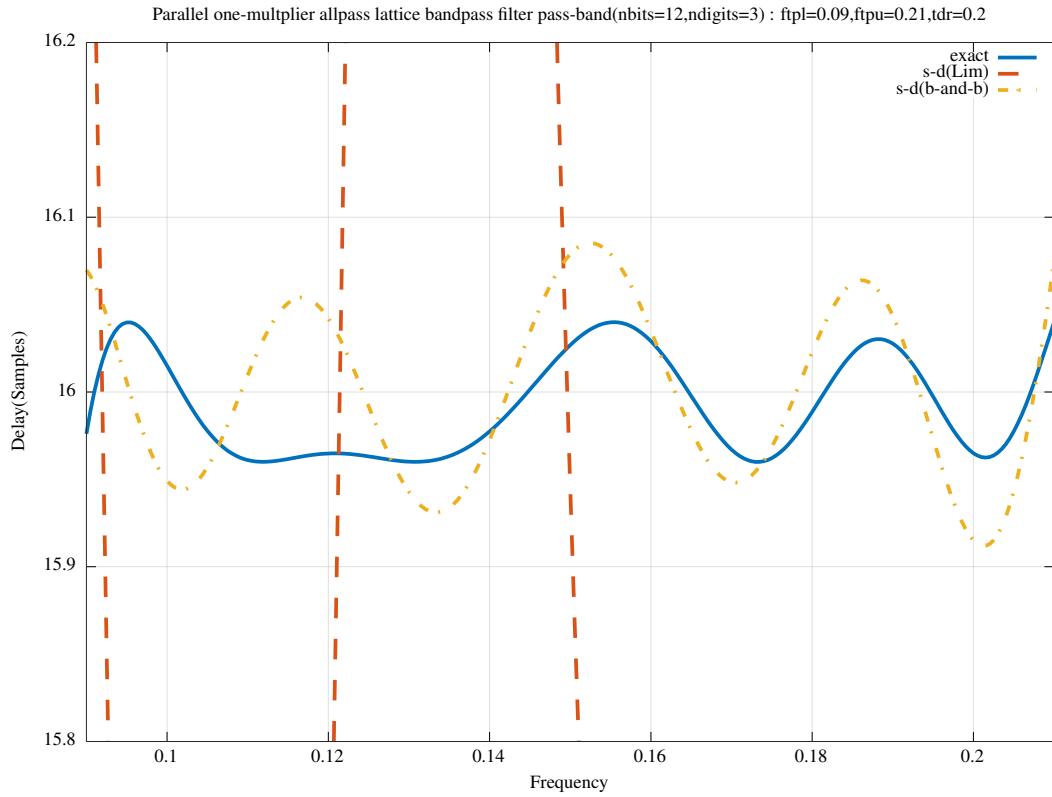

Figure 14.17: Group-delay pass-band response for a parallel Schur one-multiplier all-pass lattice band-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of Lim et al. and performing branch-and-bound search.

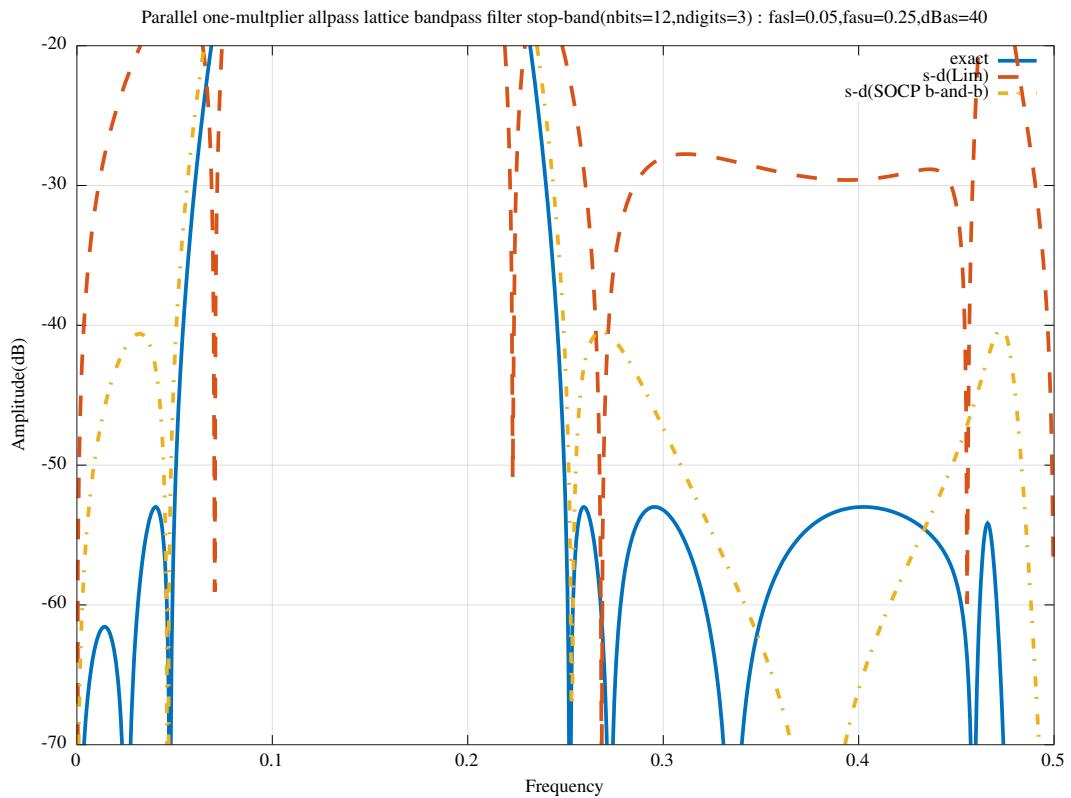

Figure 14.18: Amplitude stop-band response for a parallel Schur one-multiplier all-pass lattice band-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of Lim et al. and performing branch-and-bound search.

14.8 Branch-and-bound search for the 10-bit 3-signed-digit coefficients of a parallel all-pass lattice band-pass Hilbert IIR filter

The Octave script `branch_bound_schurOneMPAlattice_bandpass_hilbert_10_nbis_test.m` performs branch-and-bound search to optimise the response of the parallel Schur one-multiplier all-pass lattice band-pass Hilbert filter of Section 10.3.8 with 10-bit integer coefficients. The filter specification is:

```

use_best_branch_and_bound_found=1
enforce_pcls_constraints_on_final_filter=1
nbis=10 % Coefficient word length
ndigits=3 % Average number of signed digits per coef.
tol=0.0001 % Tolerance on coefficient update vector
ctol=1e-05 % Tolerance on constraints
n=1000 % Frequency points across the band
difference=1 % Use difference of all-pass filters
m1=10 % Allpass model filter 1 denominator order
m2=10 % Allpass model filter 2 denominator order
rho=0.999000 % Constraint on allpass coefficients
fapl=0.1 % Pass band amplitude response lower edge

tdr=0.200000 % Pass band group-delay response ripple(samples)
Wtp=2 % Pass band group-delay response weight
fppl=0.11 % Pass band phase response lower edge
fppu=0.19 % Pass band phase response upper edge
pd=3.500000 % Pass band nominal phase response(rad./pi)
pdr=0.040000 % Pass band phase response ripple(rad./pi)
Wpp=10 % Pass band phase response weight

```

The filter coefficients are truncated to 10 bits with 3 signed-digits. At each branch the script fixes the coefficient with the largest difference between upper and lower 3 signed-digit approximations to the floating-point value. For each sub-problem the coefficients “higher-up-the-tree” are fixed and the remaining free coefficients are SOCP PCLS optimised with the filter specification given above.

The 12-bit, 3-signed-digit, lattice coefficients found by the branch-and-bound search are:

```

A1k_min = [      -240,      432,     -188,       88, ...
             328,     -232,      138,       88, ...
            -78,        46 ]'/512;

A2k_min = [      -400,      452,     -216,       73, ...
             336,     -216,      140,       92, ...
            -74,        50 ]'/512;

```

The signed-digit lattice coefficients found by the branch-and-bound search are implemented with 59 signed-digits and 39 shift-and-add operations.

Figure 14.19 shows the amplitude pass-band response of the filter with 10-bit, 3-signed-digit coefficients. Figure 14.20 shows the corresponding filter pass-band group-delay response. Figure 14.21 shows the corresponding filter pass-band phase response (in multiples of π and corrected for delay). Figure 14.22 shows the corresponding filter stop-band amplitude response. Table 14.8 compares the cost and the number of 12 bit shift-and-add operations required to implement the coefficient multiplications found with the branch-and-bound search.

```

The filter coefficients are truncated to 12 bits allocated with an average of 3 signed-digits by the heuristic of *Ito et al.* as shown in Section 11.2. At each branch the script fixes the coefficient with the largest difference between upper and lower signed-digit approximations to the floating-point value. For each sub-problem the coefficients “higher-up-the-tree” are fixed and the remaining free coefficients are SOCP PCLS optimised with the filter specification given above.

The 12-bit, average of 3-signed-digit, lattice coefficients allocated with the algorithm of *Ito et al.* are:

```

A1k0_sd = [      -976,       1744,       -736,        384, ...
              1312,      -886,       544,        352, ...
             -312,       184 ]'/2048;

A2k0_sd = [     -1616,       1832,       -832,        336, ...
              1344,      -832,       560,        352, ...
             -288,       192 ]'/2048;

```

The 12-bit, average of 3-signed-digit, lattice coefficients allocated with the algorithm of *Ito et al.* found by the branch-and-bound search are:

```

A1k_min = [      -976,       1736,       -704,        384, ...
              1288,      -886,       576,        368, ...
             -290,       176 ]'/2048;

```

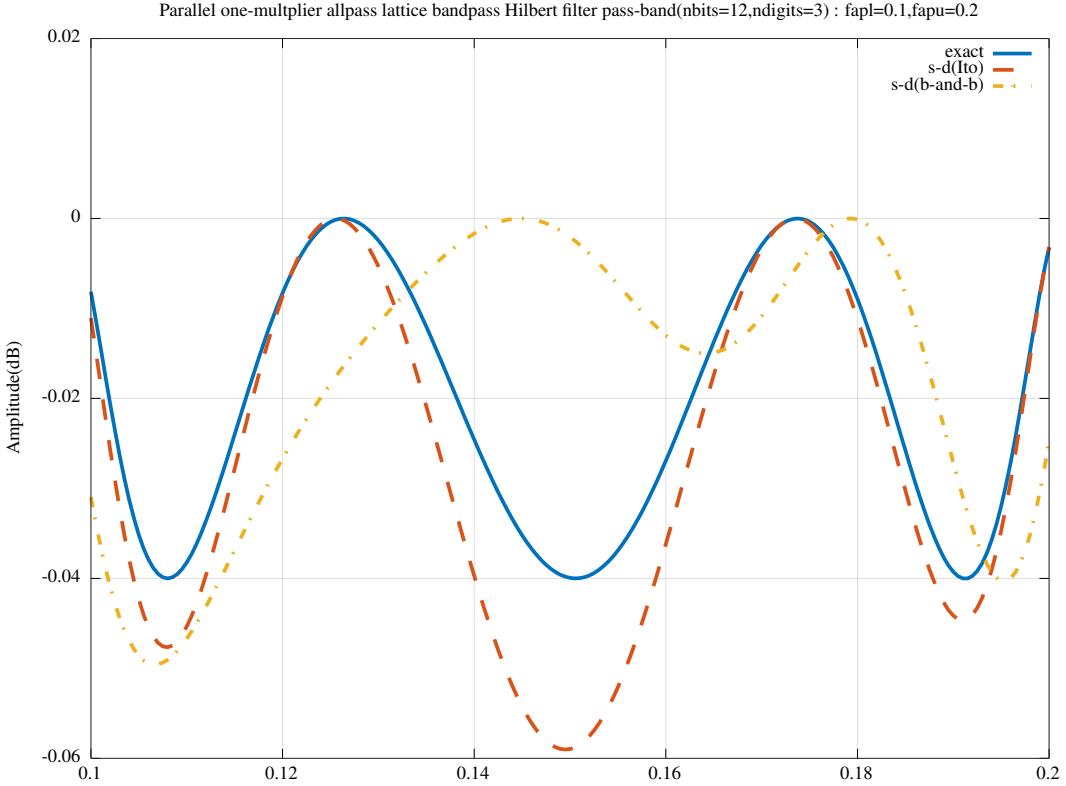

Figure 14.23: Amplitude pass-band response for a parallel Schur one-multiplier all-pass lattice band-pass Hilbert filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search.

```
A2k_min = [ -1632,      1824,      -832,       304, ...

            -258,      192 ]'/2048;
```

The signed-digit lattice coefficients found by the branch-and-bound search are implemented with 59 signed-digits and 39 shift-and-add operations.

Figure 14.23 shows the amplitude pass-band response of the filter with 12-bits 3-signed-digit coefficients allocated with the algorithm of *Ito et al.* and branch-and-bound search. Figure 14.24 shows the corresponding filter pass-band group-delay response. Figure 14.25 shows the corresponding filter pass-band phase response (in multiples of π and corrected for delay). Figure 14.26 shows the corresponding filter stop-band amplitude response. Table 14.9 compares the cost and the number of 12 bit shift-and-add operations required to implement the coefficient multiplications found by the signed-digit allocation heuristic of *Ito et al.* with the branch-and-bound search.

	Cost	Signed-digits	Shift-and-adds
Exact	0.016879		
12-bit 3-signed-digit(Ito)	0.072263	60	40
12-bit 3-signed-digit(SOCP b-and-b)	0.000960	59	39

Table 14.9: Comparison of the cost and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for a parallel Schur one-multiplier all-pass lattice band-pass Hilbert filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search.

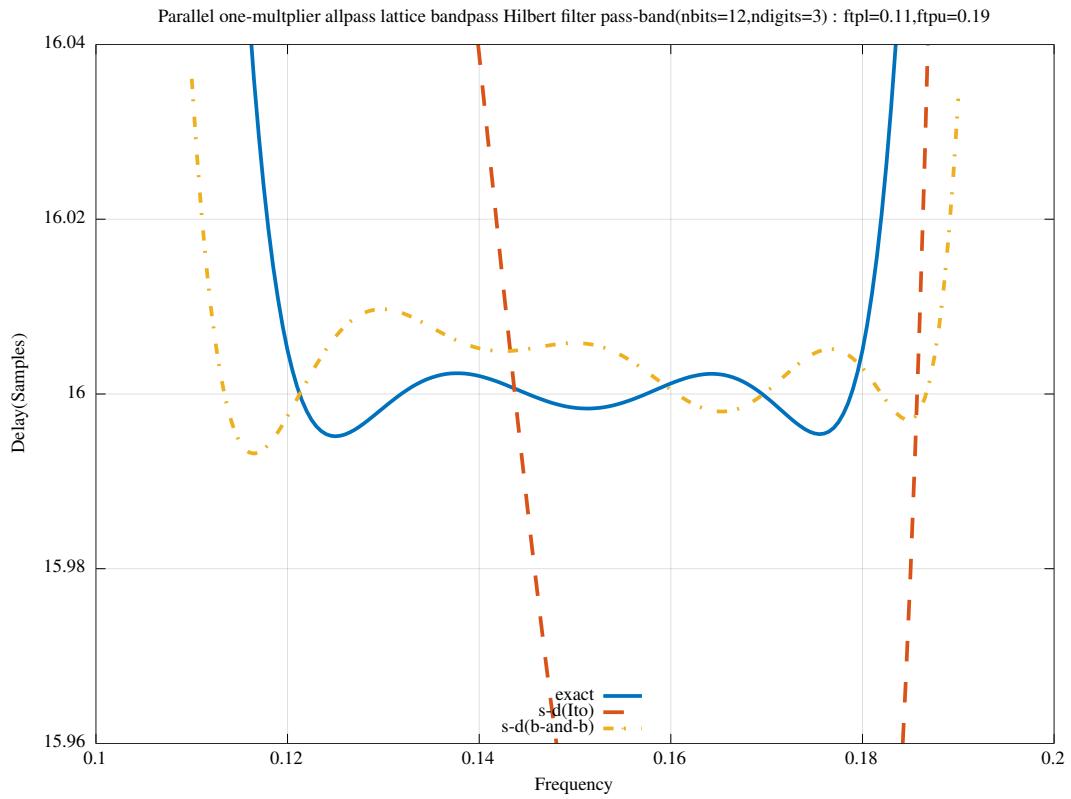

Figure 14.24: Group-delay pass-band response for a parallel Schur one-multiplier all-pass lattice band-pass Hilbert filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search.

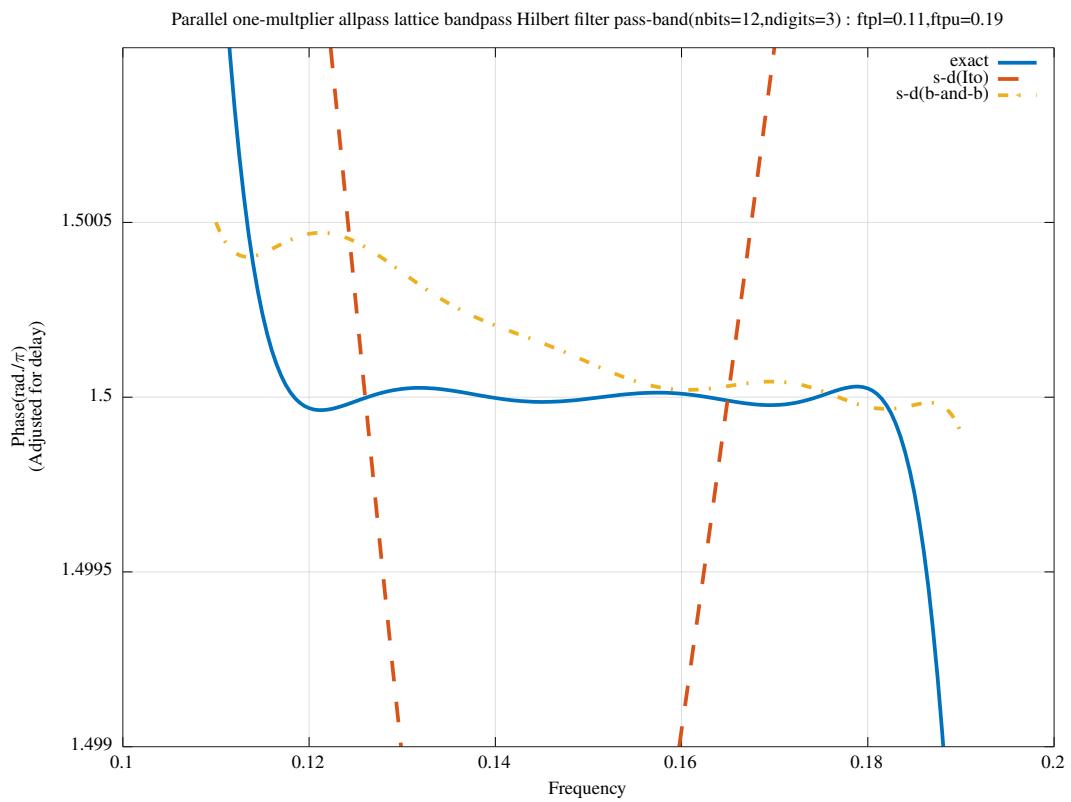

Figure 14.25: Phase pass-band response for a parallel Schur one-multiplier all-pass lattice band-pass Hilbert filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search.

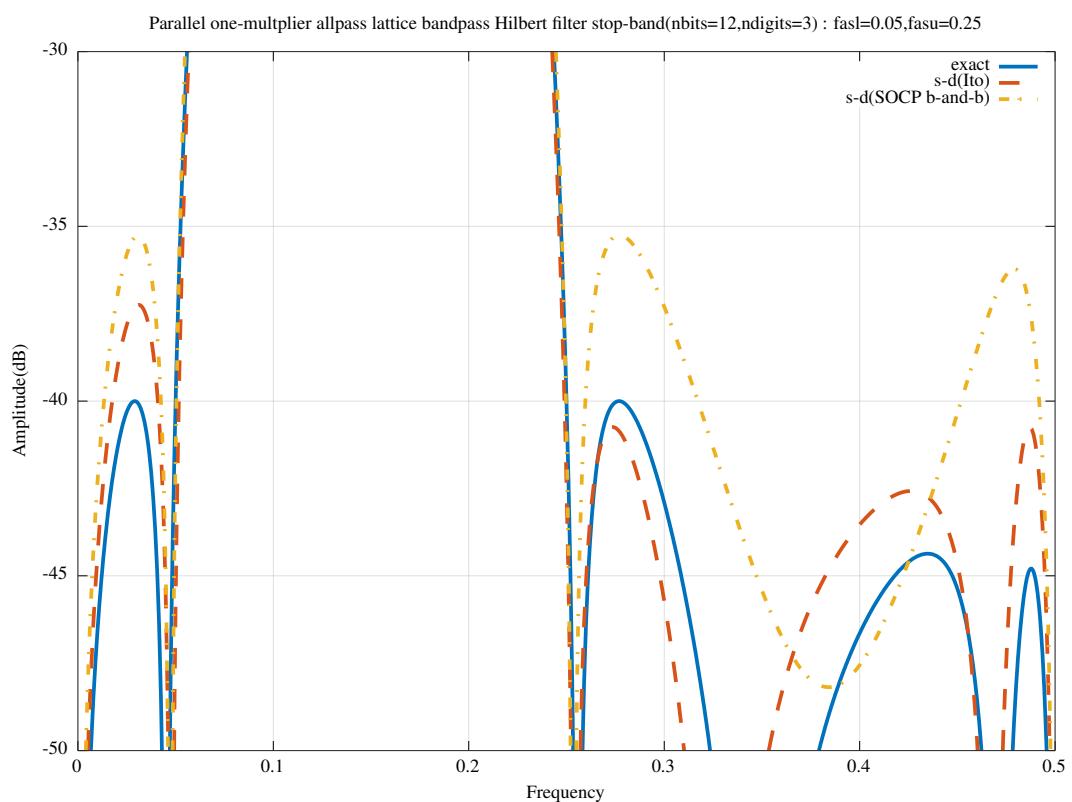

Figure 14.26: Amplitude stop-band response for a parallel Schur one-multiplier all-pass lattice band-pass Hilbert filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing branch-and-bound search.

14.10 Branch-and-bound search for the coefficients of an FRM low-pass filter implemented with 12-bits and an average of 3-signed-digits

The Octave script `branch_bound_schurOneMAPlattice_frm_12_nbts_test.m` uses the branch-and-bound heuristic to optimise the response of the FRM low-pass filter of Section 10.4.6 with 12-bit coefficients each having an average of 3 signed-digits allocated by the method of *Ito et al.*. The number of signed-digits allocated to the coefficients of the all-pass lattice filter are:

```
k_allocsd_digits = [ 1, 3, 2, 3, ...
                      1, 6, 6, 6, ...
                      6, 1 ]';
```

The number of signed-digits allocated to the distinct coefficients of the FIR masking filter are:

```
u_allocsd_digits = [ 3, 4, 1, 3, ...
                      3, 6, 3, 1, ...
                      2, 2, 1, 2, ...
                      2, 6, 1, 1, ...
                      6, 1, 1, 1, ...
                      6 ]';
```

The number of signed-digits allocated to the distinct coefficients of the FIR complementary masking filter are:

```
v_allocsd_digits = [ 5, 3, 6, 1, ...
                      2, 3, 6, 2, ...
                      2, 1, 2, 1, ...
                      6, 6, 1, 1, ...
                      6, 2, 2, 1, ...
                      6 ]';
```

The filter specification is:

```
n=1000 % Frequency points across the band
tol=0.0001 % Tolerance on coefficient update vector
ctol=1e-05 % Tolerance on constraints
n=1000 % Frequency points across the band
mr=10 % Allpass model filter denominator order
Mmodel=9 % Model filter FRM decimation factor
Dmodel=9 % Model filter nominal pass band group delay
dmask=20 % FIR masking filter delay
fap=0.3 % Magnitude-squared pass band edge
dBap=0.2 % Pass band magnitude peak-to-peak ripple
Wap=1 % Pass band magnitude-squared weight
fas=0.3105 % Magnitude-squared stop band edge
dBas=37 % Stop band magnitude minimum attenuation
Was=10 % Stop band magnitude-squared weight
ftp=0.3 % Delay pass band edge
tp=101 % Pass band nominal delay
tpr=tp/101 % Pass band delay peak-to-peak ripple
Wtp=1 % Pass band magnitude-squared weight
fpp=0.3 % Phase pass band edge
ppr=0.02*pi % Pass band phase peak-to-peak ripple (rad.)
Wpp=0.1 % Phase pass band weight
rho=0.992188 % Constraint on allpass pole radius
```

The filter coefficients found by the branch-and-bound search^b are:

```
k_min = [ -16,      1184,        40,       -292, ...
            -8,       117,         15,       -55, ...
            -7,       16 ]'/2048;
```

^bThe search was stopped after about 36 hours.

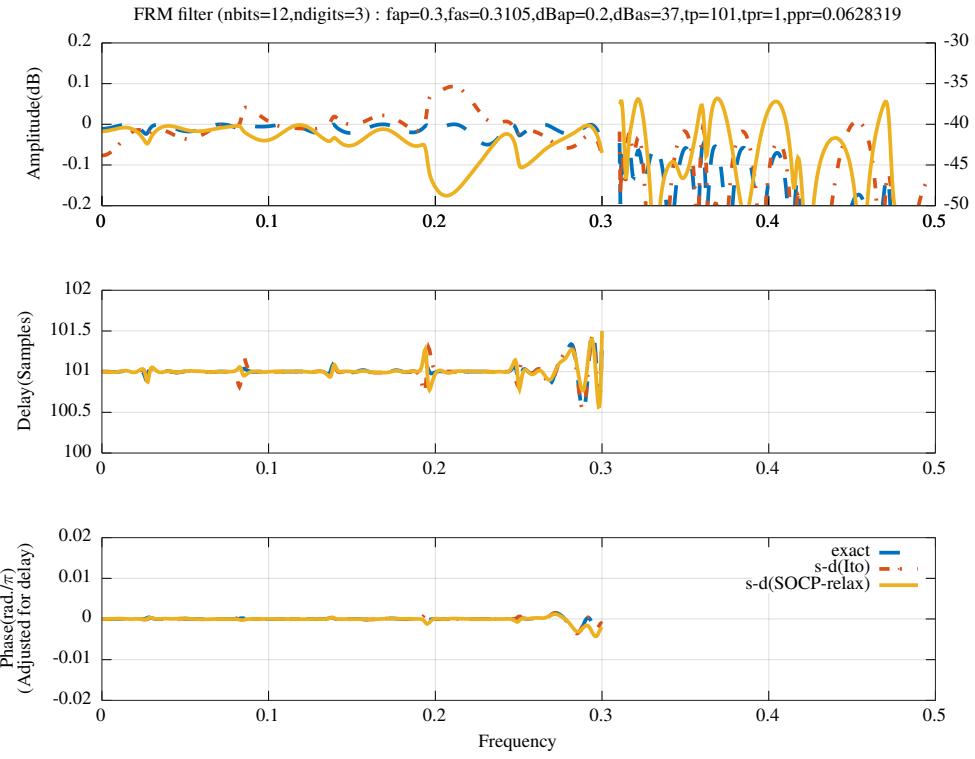

Figure 14.27: Comparison of the amplitude, delay and phase responses of an FRM low-pass filter with exact and 12 bit coefficients with an average of 3-signed-digits allocated by the method of *Ito et al.* and with the coefficients found by branch-and-bound search

```

epsilon_min = [ 1, 1, -1, 1, ...
               1, -1, -1, 1, ...
               1, -1 ];

u_min = [ 1168,      623,      -128,      -168, ...
           104,        64,       -88,        -8, ...
           72,       -28,       -32,        28, ...
           18,       -17,       -8,        16, ...
           -4,        -8,        8,         1, ...
           -7 ] '/2048;

v_min = [ -1361,     -560,      275,        8, ...
           -132,       104,        6,      -68, ...
            60,        -4,      -36,       32, ...
             4,       -19,       16,        4, ...
           -12,        12,       -4,      -4, ...
            6 ] '/2048;

```

Figure 14.27, compares the amplitude, delay and phase responses of the FRM low-pass filter with exact and 12-bit coefficients with an average of 3-signed-digits allocated by the method of *Ito et al.* and with the coefficients found by branch-and-bound search. Table 14.10 compares the cost and the number of 12 bit shift-and-add operations required to implement the coefficient multiplications found by branch-and-bound search.

	Cost	Signed-digits	Shift-and-adds
Exact	0.001537		
12-bit 3-signed-digit(Ito)	0.001799	101	49
12-bit 3-signed-digit(branch-and-bound)	0.001491	102	50

Table 14.10: Comparison of the cost and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for an FRM low-pass filter with 12-bit coefficients with an average of 3-signed-digits allocated by the method of *Ito et al.* and with the coefficients found by branch-and-bound search

14.11 Branch-and-bound search for the coefficients of an FRM Hilbert filter implemented with 12-bits and 2-signed-digits

The Octave script *branch_bound_schurOneMAPlattice_frm_hilbert_12_nbts_test.m* uses the branch-and-bound heuristic to optimise the response of the FRM Hilbert filter of Section 10.4.8 with 12-bit 2-signed-digit coefficients. The filter specification is:

```
n=800 % Frequency points across the band
tol=1e-05 % Tolerance on coefficient update vector
ctol=1e-05 % Tolerance on constraints
n=800 % Frequency points across the band
mr=5 % Allpass model filter denominator order
Mmodel=7 % Model filter FRM decimation factor
Dmodel=9 % Model filter nominal pass band group delay
dmask=16 % FIR masking filter delay
fap=0.01 % Magnitude-squared pass band edge
fas=0.49 % Magnitude-squared stop band edge
dBap=0.2 % Pass band magnitude-squared peak-to-peak ripple
Wap=1 % Pass band magnitude-squared weight
ftp=0.01 % Delay pass band edge
fts=0.49 % Delay stop band edge
tp=79 % Pass band nominal delay
tpr=tp/90 % Pass band delay peak-to-peak ripple
Wtp=1 % Pass band magnitude-squared weight
fpp=0.01 % Phase pass band edge
fps=0.49 % Phase stop band edge
pp=-0.5*pi % Pass band phase peak-to-peak ripple (rad.)
ppr=pi/360 % Pass band phase peak-to-peak ripple (rad.)
Wpp=0.005 % Phase pass band weight
```

The truncation of the last coefficient is, by necessity, not PCLS optimised so the final set of coefficients may not meet the PCLS specifications. The filter coefficients found by the branch-and-bound search are:

```
k_min = [ -1152,      -264,       -96,       -36, ...
           -12 ] '/2048;

u_min = [      0,       -3,       -16,       -24, ...
           -63,      -72,      -112,      -120, ...
           896 ] '/2048;

v_min = [     14,        9,       18,        8, ...
           -12,      -63,      -160,     -640 ] '/2048;
```

Figures 14.28, 14.29 and 14.30 compare the amplitude, phase and delay responses of the FRM Hilbert filter with exact and 12-bit 2-signed-digit coefficients and with the 12-bit 2-signed-digit coefficients found by branch-and-bound search. Figure 14.31 compares the amplitude and phase responses of a linear phase FIR Hilbert filter with 12-bit 2-signed-digit coefficients and the FRM Hilbert filter with 12 bit 2-signed digit integer coefficients found by branch-and-bound search. The group delay of the FIR Hilbert filter is the nominal delay of the FRM Hilbert filter:

```
b=remez(2*tp,2*[fap fas],[1 1],1,"hilbert");
```

The FIR Hilbert filter coefficients have not been optimised. Table 14.11 compares the cost and the number of 12 bit shift-and-add operations required to implement the coefficient multiplications found by the branch-and-bound search.

14.12 Branch-and-bound search for the 12-bit 2-signed-digit coefficients of an FIR Hilbert filter

The Octave script `branch_bound_directFIRhilbert_12_nbites_test.m` uses the branch-and-bound heuristic to optimise the response of a direct-form FIR Hilbert filter with 12-bit 2-signed-digit coefficients having a similar specification to the FIR Hilbert filter of Appendix L.3.1. An average of 2 signed-digits are allocated to each non-zero coefficient with the heuristic of *Ito et al.*. The Octave script `directFIRhilbert_allocsd_test.m` compares the heuristics of *Lim et al.* and *Ito et al.* for coefficient wordlengths from 6 to 16 bits. The direct-form FIR Hilbert filter specification is:

```
M=40 % Number of distinct coefficients
nbits=12 % Coefficient bits
ndigits=2 % Nominal average coefficient signed-digits
tol=0.0001 % Tolerance on coefficient. update
maxiter=400 % iteration limit
fapl=0.01 % Amplitude pass band lower edge
fapu=0.49 % Amplitude pass band upper edge
Wap=1 % Amplitude pass band weight
Was=0 % Amplitude stop band weight
```

The filter has 40 distinct non-zero coefficients and the filter group-delay is 80 samples. The distinct non-zero filter coefficients found by the branch-and-bound search are:

```
hM_min = [ 1304,      432,      258,      183, ...
           140,       112,       96,       80, ...
           69,        60,       52,       48, ...
           40,        36,       32,       30, ...
           28,        24,       20,       18, ...
           16,        16,       14,       12, ...
           10,         9,        8,        8, ...
            6,         4,        4,        4, ...
            2,         2,        2,        2, ...
            1,         1,        1,        1 ]'/2048;
```

Figure 14.32, compares the amplitude responses of the FIR Hilbert filter with exact, 12-bit 2-signed-digit coefficients, 12-bit 2-signed-digit coefficients with signed-digits allocated by the heuristic of *Ito et al.* and with the 12-bit 2-signed-digit coefficients found by branch-and-bound search. Table 14.12 compares the cost and the number of 12 bit shift-and-add operations required to implement the coefficient multiplications found by the branch-and-bound search. The FIR filter structure requires an extra 80 additions.

	Cost	Signed-digits	Shift-and-adds
Exact	9.57e-07		
12-bit 2-signed-digit	4.24e-04	71	31
12-bit 2-signed-digit(Ito)	1.53e-05	72	32
12-bit 2-signed-digit(branch-and-bound)	1.28e-05	72	32

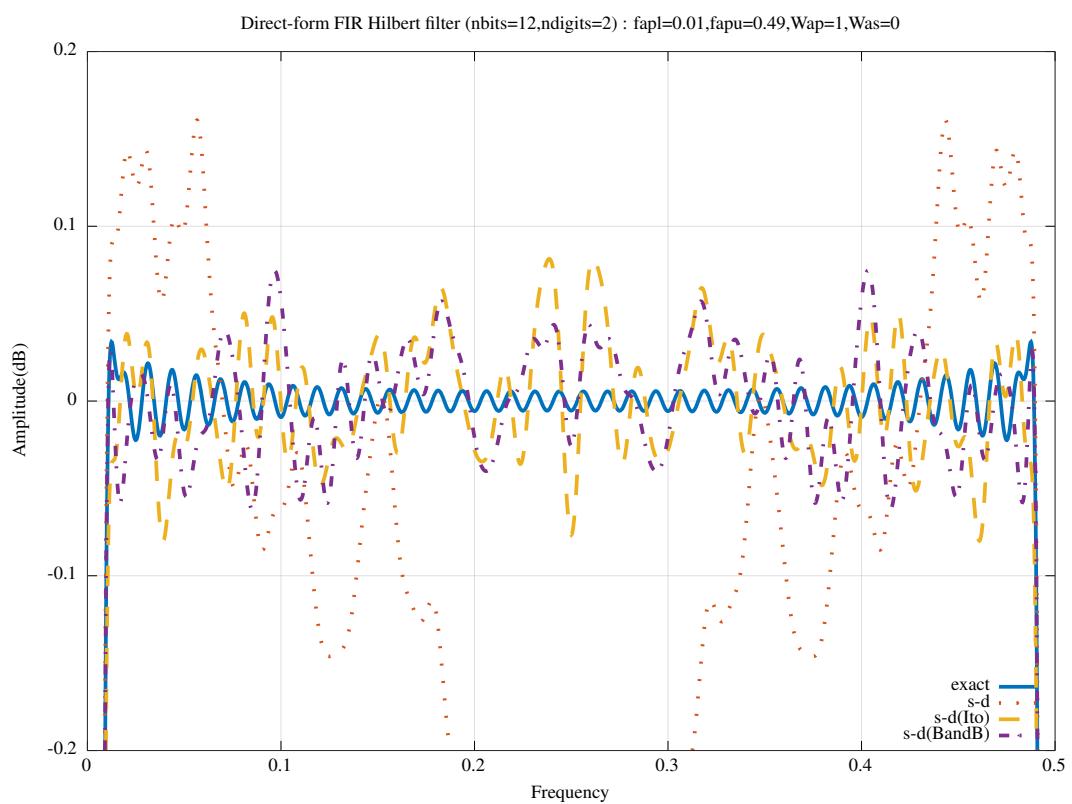

Figure 14.32: Comparison of the amplitude response of a direct-form FIR Hilbert filter with exact and 12-bit 2-signed digit integer coefficients found by branch-and-bound search

14.13 Branch-and-bound search for the 12-bit 2-signed-digit coefficients of an FIR Hilbert band-pass filter

The Octave script `branch_bound_directFIRhilbert_bandpass_12_nbits_test.m` uses the branch-and-bound heuristic to optimise the response of a direct-form FIR Hilbert band-pass filter with 12-bit 2-signed-digit coefficients having a similar bandwidth specification to the FIR Hilbert band-pass filter of Appendix L.3.2. An average of 2 signed-digits are allocated to each non-zero coefficient with the heuristic of *Ito et al.*. The direct-form FIR Hilbert filter specification is:

```
M=8 % Number of distinct coefficients
nbits=12 % Coefficient bits
ndigits=2 % Nominal average coefficient signed-digits
tol=0.0001 % Tolerance on coefficient. update
maxiter=400 % iteration limit
fapl=0.16325 % Amplitude pass band lower edge
fapu=0.33675 % Amplitude pass band upper edge
Wap=2 % Amplitude pass band weight
Was=1 % Amplitude stop band weight
```

The filter has 8 distinct non-zero coefficients and the filter group-delay is 16 samples. The distinct non-zero filter coefficients found by the allocation of signed-digits with the heuristic of *Ito et al.* are:

```
hM_sd = [ 868, -327, -112, 128, ...
           32, -64, -8, 20 ]'/2048;
```

and by branch-and-bound search are:

```
hM_min = [ 872, -327, -120, 128, ...
            32, -64, -8, 24 ]'/2048;
```

Figure 14.33, compares the amplitude responses of the FIR Hilbert band-pass filter with exact, 12-bit 2-signed-digit coefficients, 12-bit 2-signed-digit coefficients with signed-digits allocated by the heuristic of *Ito et al.* and with the 12-bit 2-signed-digit coefficients found by branch-and-bound search. Table 14.13 compares the cost and the number of 12 bit shift-and-add operations required to implement the coefficient multiplications found by the branch-and-bound search. The FIR filter structure requires an extra 16 additions.

	Cost	Signed-digits	Shift-and-adds
Exact	4.99e-05		
12-bit 2-signed-digit	5.39e-04	16	8
12-bit 2-signed-digit(Ito)	7.91e-05	16	8
12-bit 2-signed-digit(branch-and-bound)	4.96e-05	16	8

Table 14.13: Comparison of the cost and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for a direct-form FIR Hilbert band-pass filter with 12-bit 2-signed-digit coefficients found by branch-and-bound search

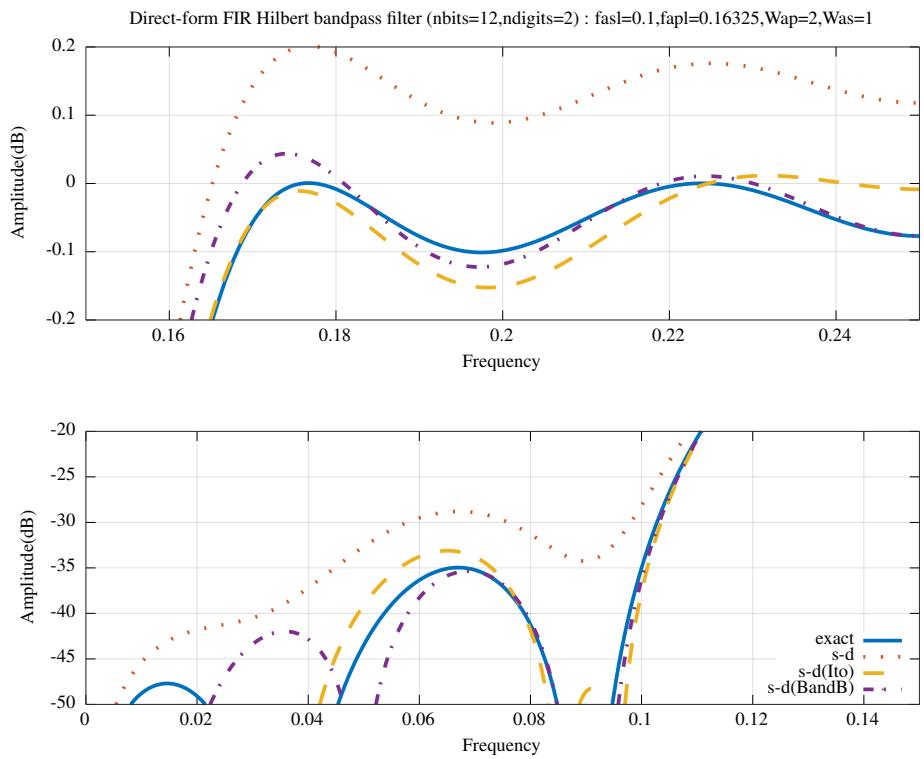

Figure 14.33: Comparison of the amplitude response of a direct-form FIR Hilbert bandpass filter with exact and 12-bit 2-signed digit integer coefficients found by branch-and-bound search

Chapter 15

Successive coefficient relaxation search for signed-digit filter coefficients

This section describes the results of experiments in which I fix one coefficient and minimise the objective function over the remaining free coefficients. This is called a *relaxation* of the optimisation. The relaxation is repeated until all the coefficients are fixed.

15.1 SOCP-relaxation search for the signed-digit coefficients of a direct-form symmetric bandpass FIR filter

The Octave script `socp_relaxation_directFIRsymmetric_bandpass_12_nbits_test.m` performs successive SOCP relaxations to optimise the response of a direct-form symmetric band-pass FIR filter. The filter specification is:

```
nbits=12 % Coefficient bits
ndigits=3 % Nominal average coefficient signed-digits
tol=1e-05 % Tolerance on coef. update
ctol=1e-05 % Tolerance on constraints
maxiter=5000 % SOCP iteration limit
npoints=1000 % Frequency points across the band
fapl=0.1 % Amplitude pass band lower edge
fapu=0.2 % Amplitude pass band upper edge
dBap=2 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
fasl=0.05 % Amplitude stop band(1) lower edge
fasu=0.25 % Amplitude stop band(1) upper edge
dBas=43 % Amplitude stop band(1) peak-to-peak ripple
fasll=0.04 % Amplitude stop band(2) lower edge
fasuu=0.26 % Amplitude stop band(2) upper edge
dBass=37 % Amplitude stop band(2) peak-to-peak ripple
Wasl=40 % Amplitude lower stop band weight
Wasu=40 % Amplitude upper stop band weight
```

The filter coefficients are truncated to 12 bits allocated with an average of 3 signed-digits by the heuristic of *Ito et al.* as shown in Section 11.2.

At each coefficient relaxation step the script finds the upper and lower signed-digit approximations to the current set of active coefficients and selects the coefficient with the largest difference in those approximations. The corresponding bounds are set in the bounds for that coefficient passed to the Octave function `directFIRsymmetric_socp_mmse`. The results of this MMSE optimisation are then passed to `directFIRsymmetric_slb` for PCLS optimisation. The resulting PCLS coefficient value selects the closer of the upper or lower signed-digit values as the final choice for that coefficient. The truncation of the last coefficient is, by necessity, not PCLS optimised so the final set of coefficients may not meet the PCLS specifications.

The distinct direct-form symmetric FIR bandpass filter coefficients found by the SOCP-relaxation search are:

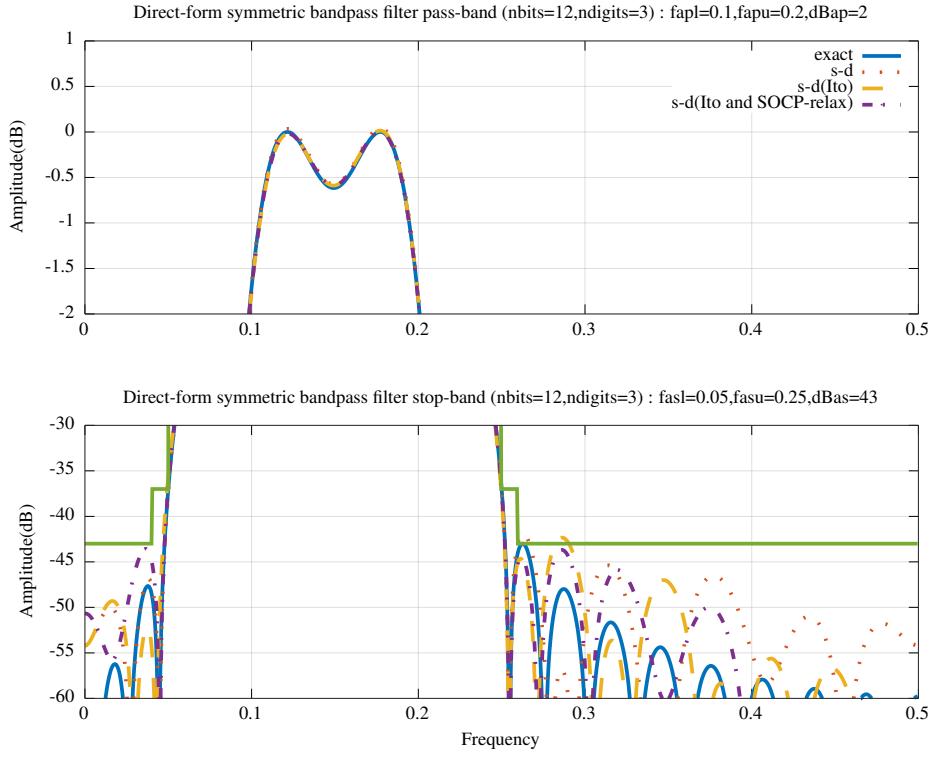

Figure 15.1: Comparison of the amplitude responses for a direct-form symmetric FIR bandpass filter with 12-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SOCP-relaxation search

```
hM_min = [      -1,      -16,      -33,      -15, ...
            39,       68,       32,       -8, ...
            28,       82,       -2,     -236, ...
           -366,     -142,      302,      530 ]'/2048;
```

Figure 15.1 compares the responses of the filter with exact, 12-bit signed-digit coefficients allocated with the algorithm of *Ito et al.* and 12-bit signed-digit coefficients allocated with the algorithm of *Ito et al.* and SOCP-relaxation search. Table 15.1 compares the cost and the number of 12 bit shift-and-add operations required to implement the 16 distinct coefficient multiplications found by the signed-digit allocation heuristic of *Ito et al.* with the SOCP-relaxation search.

	Cost	Signed-digits	Shift-and-adds
Exact	0.0009		
12-bit 3-signed-digit	0.000971	39	23
12-bit 3-signed-digit(Ito)	0.001018	36	20
12-bit 3-signed-digit(SOCP-relax)	0.001038	36	20

Table 15.1: Comparison of the cost and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for a direct-form symmetric FIR bandpass filter with 12-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SOCP-relaxation search

15.2 SQP-relaxation search for the signed-digit coefficients of a lattice bandpass IIR filter

The Octave script *sqp_relaxation_schurOneMlattice_bandpass_10_nbis_test.m* performs successive SQP relaxations to optimise the response of the SQP optimised band-pass Schur one-multiplier lattice filter of Section 10.3.3. The filter specification is:

```

nbis=10 % Coefficient bits
ndigits=3 % Nominal average coefficient signed-digits
tol=0.0001 % Tolerance on coef. update
ctol=0.0001 % Tolerance on constraints
maxiter=2000 % SQP iteration limit
npoints=250 % Frequency points across the band
length(c0)=21 % Num. tap coefficients
sum(k0~=0)=10 % Num. non-zero all-pass coef.s
dmax=0.250000 % Constraint on norm of coefficient SQP step size
rho=0.998047 % Constraint on allpass coefficients
fapl=0.1 % Amplitude pass band lower edge
fapu=0.2 % Amplitude pass band upper edge
dBap=2 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
ftpl=0.09 % Delay pass band lower edge
ftpup=0.21 % Delay pass band upper edge
tp=16 % Nominal passband filter group delay
tpr=0.2 % Delay pass band peak-to-peak ripple
Wtp=5 % Delay pass band weight
fasl=0.05 % Amplitude stop band(1) lower edge
fasu=0.25 % Amplitude stop band(1) upper edge
dBas=33 % Amplitude stop band(1) peak-to-peak ripple
fasll=0.04 % Amplitude stop band(2) lower edge
fasuu=0.26 % Amplitude stop band(2) upper edge
dBass=40 % Amplitude stop band(2) peak-to-peak ripple
Wasl=500000 % Amplitude lower stop band weight
Wasu=1000000 % Amplitude upper stop band weight

```

The filter coefficients are truncated to 10 bits allocated with an average of 3 signed-digits by the heuristic of *Ito et al.* as shown in Section 11.2.

At each coefficient relaxation step the script finds the upper and lower signed-digit approximations to the current set of active coefficients and selects the coefficient with the largest difference in those approximations. The corresponding bounds are set in the bounds for that coefficient passed to the Octave function *schurOneMlattice_sqp_mmse*. The results of this MMSE optimisation are then passed to *schurOneMlattice_slb* for PCLS optimisation. The resulting PCLS coefficient value selects the closer of the upper or lower signed-digit values as the final choice for that coefficient. The truncation of the last coefficient is, by necessity, not PCLS optimised so the final set of coefficients may not meet the PCLS specifications.

The filter coefficients found by the SQP-relaxation search are:

```

k_min = [      0,      336,      0,      256, ...
            0,      176,      0,      216, ...
            0,      150,      0,      128, ...
            0,       77,      0,       54, ...
            0,       18,      0,        8 ]'/512;

c_min = [     34,      -16,     -168,     -240, ...
           -63,       80,      208,      138, ...
           -2,      -46,      -40,       -4, ...
           -5,      -16,      -11,        5, ...
          14,        8,        1,       -1, ...
           2 ]'/512;

```

Figure 15.2 compares the pass-band responses of the filter with exact, 10-bit signed-digit coefficients allocated with the algorithm of *Ito et al.* and 10-bit signed-digit coefficients allocated with the algorithm of *Ito et al.* and SQP-relaxation search. Figure 15.3 shows the filter stop-band response and Figure 15.4 shows the filter pass-band group delay response. Table 15.2 compares the cost and the number of 10 bit shift-and-add operations required to implement the 31 coefficient multiplications found by the signed-digit allocation heuristic of *Ito et al.* with the SQP-relaxation search. A further 51 additions are required by the lattice filter structure.

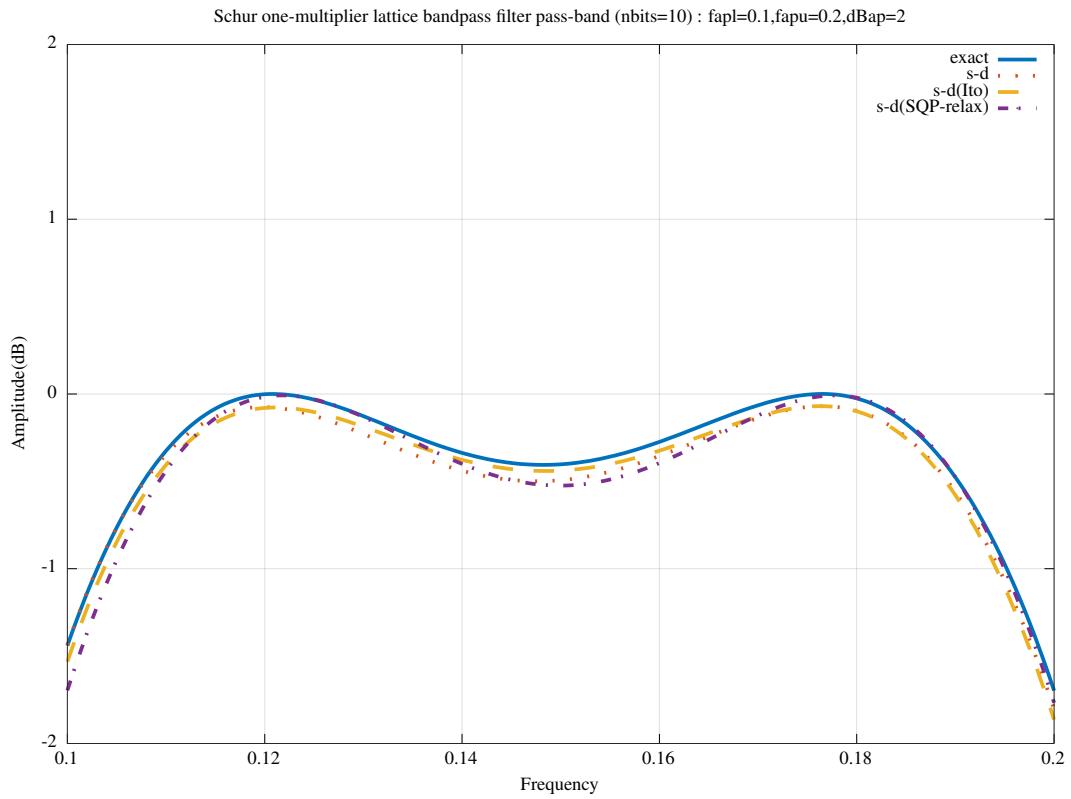

Figure 15.2: Comparison of the pass-band amplitude responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SQP-relaxation search

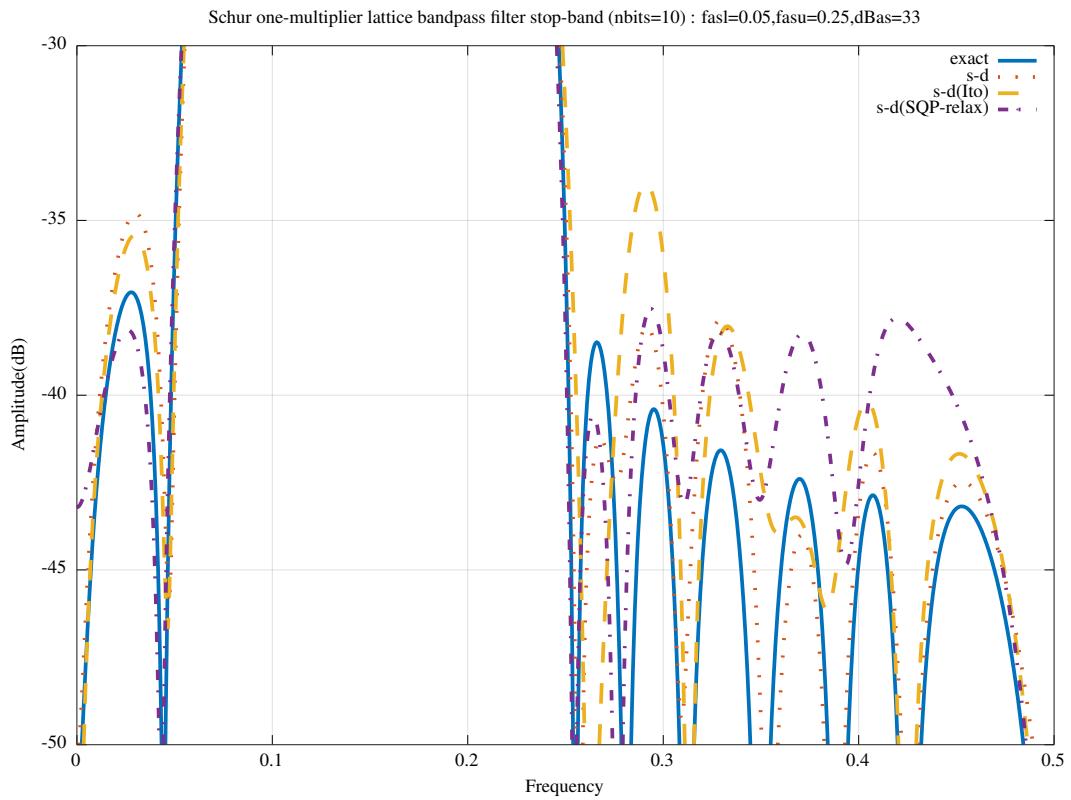

Figure 15.3: Comparison of the stop-band amplitude responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SQP-relaxation search

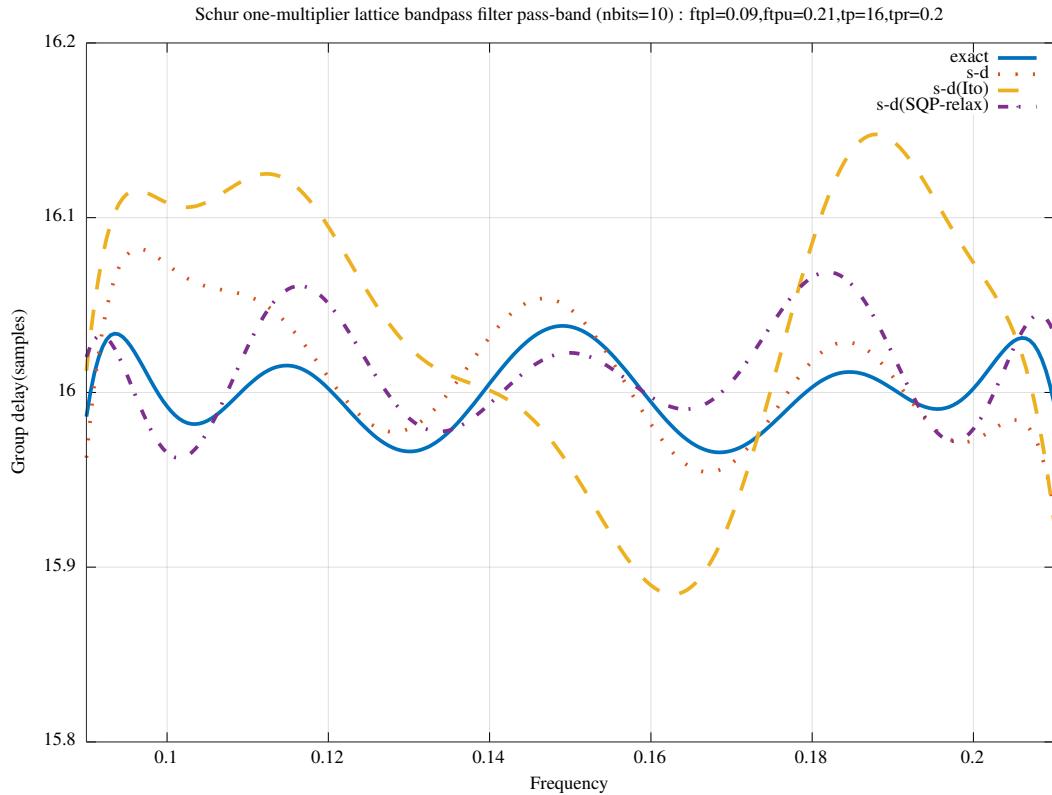

Figure 15.4: Comparison of the pass-band group delay responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SQP-relaxation search

	Cost	Signed-digits	Shift-and-adds
Exact	0.0158		
10-bit 3-signed-digit	0.0296	73	42
10-bit 3-signed-digit(Ito)	0.0718	64	33
10-bit 3-signed-digit(SQP-relax)	0.0309	64	33

Table 15.2: Comparison of the cost and number of 10-bit shift-and-add operations required to implement the coefficient multiplications for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SQP-relaxation search

15.3 SQP-relaxation search for the signed-digit coefficients of a lattice lowpass IIR filter

The Octave script `sqp_relaxation_schurOneMlattice_lowpass_10_nbites_test.m` performs successive SQP relaxations to optimise the response of the low-pass Schur one-multiplier lattice filter of Section 10.3.2 with 10-bit integer coefficients. The filter specification is:

```

tol=0.0001 % Tolerance on coefficient update vector
ctol=0.0001 % Tolerance on constraints
nbits=10 % coefficient length in bits
ndigits=3 % signed-digits per coefficient
n=400 % Frequency points across the band
length(c0)=11 % Tap coefficients
sum(k0~=0)=6 % Num. non-zero lattice coefficients
dmax=0.050000 % Constraint on norm of coefficient SQP step size
rho=0.992188 % Constraint on lattice coefficient magnitudes
fap=0.15 % Amplitude pass band edge
dBap=0.4 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
ftp=0.25 % Delay pass band edge
tp=10 % Nominal pass band filter group delay
tpr=0.2 % Delay pass band peak-to-peak ripple
Wtp=0.5 % Delay pass band weight
fas=0.3 % Amplitude stop band edge
dBas=37 % amplitude stop band peak-to-peak ripple
Was=20000 % Amplitude stop band weight

```

The filter coefficients are truncated to 10 bits allocated with an average of 3 signed-digits by the heuristic of *Lim et al.* as shown in Section 11.1. At each coefficient relaxation step the script finds the upper and lower signed-digit approximations to the current set of active coefficients and selects the coefficient with the largest difference in those approximations. The corresponding bounds are set in the bounds for that coefficient passed to the Octave function `schurOneMlattice_sqp_mmse`. The results of this MMSE optimisation are then passed to `schurOneMlattice_slb` for PCLS optimisation. The resulting PCLS coefficient value selects the closer of the upper or lower signed-digit values as the final choice for that coefficient. The truncation of the last coefficient is, by necessity, not PCLS optimised so the final set of coefficients may not meet the PCLS specifications.

The filter coefficients found by the SQP-relaxation search are:

```

k_min = [ -358,      355,      -303,      215, ...
           -112,       32,          0,          0, ...
            0,        0 ]'/512;

c_min = [   140,      350,       43,      -44, ...
           -22,        4,        12,         4, ...
            -4,       -4,        0 ]'/512;

```

Figure 15.5 shows the amplitude and group-delay responses of the filter with 10-bit 3-signed-digit coefficients allocated with the algorithm of *Lim et al.* and SQP-relaxation search. Figure 15.6 shows the corresponding filter pass-band response and Figure 15.7 shows the filter pole-zero plot. Table 15.3 compares the cost and the number of 10 bit shift-and-add operations required to implement the coefficient multiplications found by the signed-digit allocation heuristic of *Lim et al.* with the SQP-relaxation search.

	Cost	Signed-digits	Shift-and-adds
Exact	0.001253		
10-bit 3-signed-digit(Lim)	0.019346	42	26
10-bit 3-signed-digit(SQP-relax)	0.000629	44	28

Table 15.3: Comparison of the cost and number of 10-bit shift-and-add operations required to implement the coefficient multiplications for a Schur one-multiplier lattice low-pass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SQP-relaxation search.

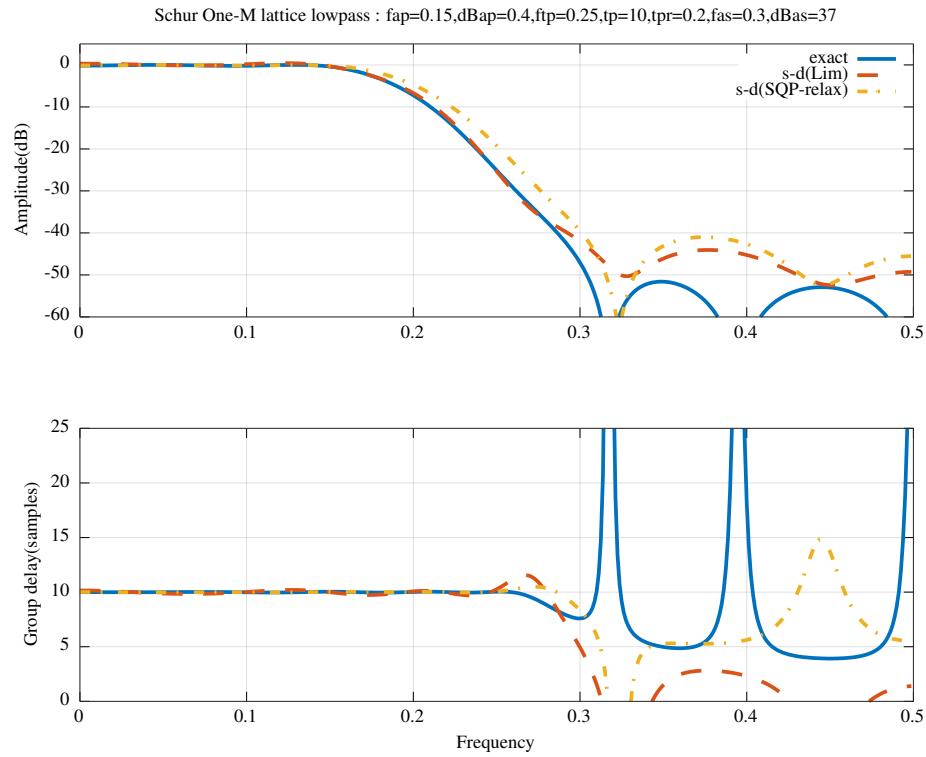

Figure 15.5: Amplitude and group-delay responses for a Schur one-multiplier lattice low-pass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SQP-relaxation search.

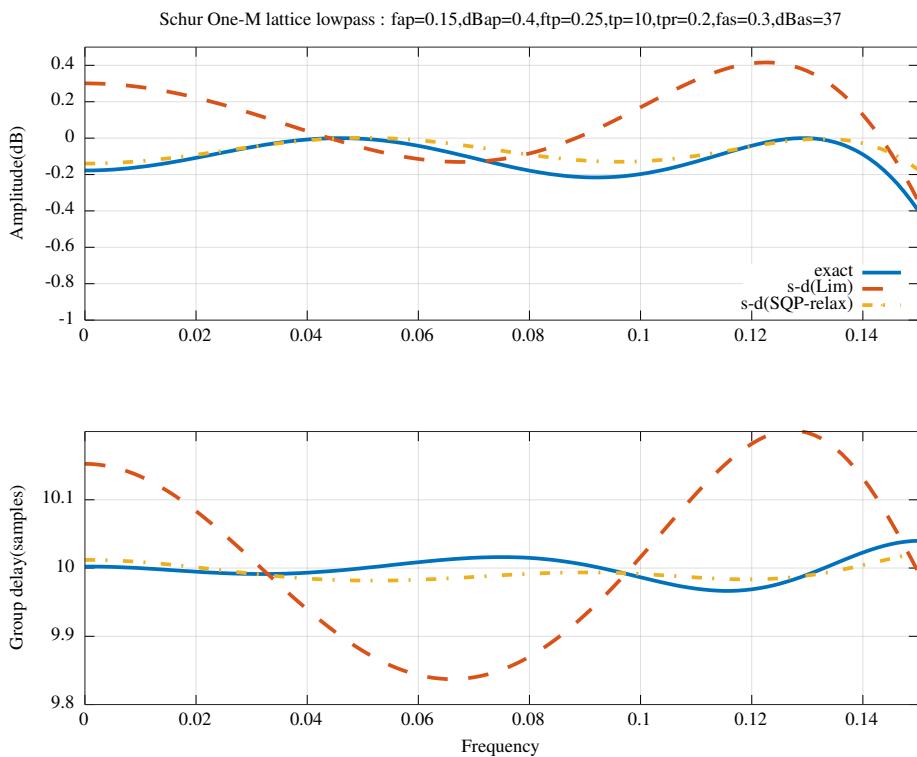

Figure 15.6: Amplitude and group-delay pass-band responses for a Schur one-multiplier lattice low-pass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SQP-relaxation search.

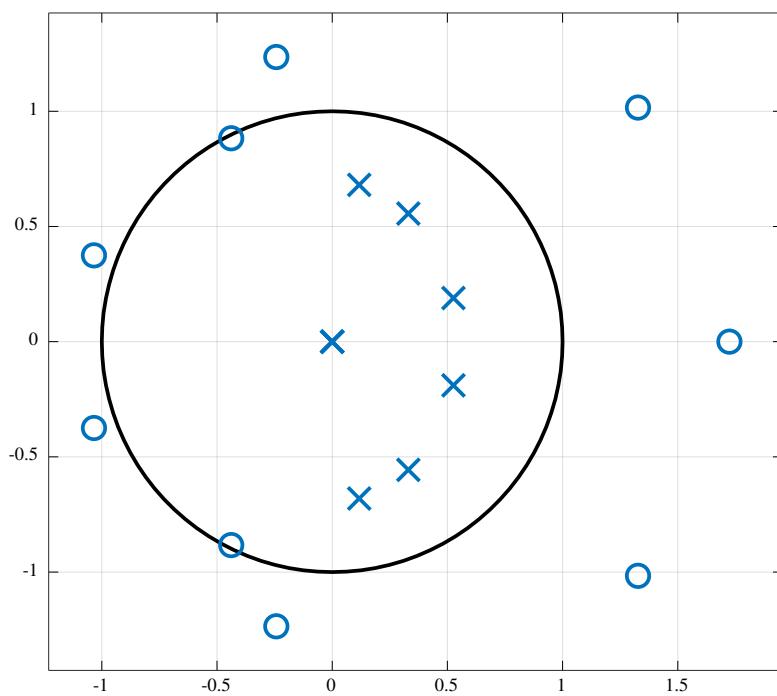

Figure 15.7: Pole-zero plot for a Schur one-multiplier lattice low-pass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SQP-relaxation search.

15.4 SOCP-relaxation search for the signed-digit coefficients of a parallel all-pass lattice low-pass IIR filter

The Octave script *socp_relaxation_schurOneMPAlattice_lowpass_12_nbites_test.m* performs successive SOCP relaxations to optimise the response of the parallel Schur one-multiplier all-pass lattice low-pass filter of Section 10.3.6 with 12-bit integer coefficients. The filter specification is:

```
nbits=12 % Coefficient word length
ndigits=3 % Average number of signed digits per coef.
tol=0.0001 % Tolerance on coefficient update vector
ctol=5e-07 % Tolerance on constraints
n=1000 % Frequency points across the band
m1=11 % Allpass model filter 1 denominator order
m2=12 % Allpass model filter 2 denominator order
rho=0.992188 % Constraint on allpass coefficients
fap=0.125 % Amplitude pass band edge
dBap=0.2 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
Wat=0 % Amplitude transition band weight
fas=0.25 % Amplitude stop band edge
dBas=50 % amplitude stop band peak-to-peak ripple
Was=100 % Amplitude stop band weight
ftp=0.175 % Delay pass band edge
td=11.5 % Nominal pass band filter group delay
tdr=0.06 % Delay pass band peak-to-peak ripple
Wtp=2 % Delay pass band weight
```

The filter weights differ from those used in Section 14.4.

The filter coefficients are truncated to 12 bits allocated with an average of 3 signed-digits by the heuristic of *Lim et al.* as shown in Section 11.1. At each coefficient relaxation step the script finds the upper and lower signed-digit approximations to the current set of active coefficients and selects the coefficient with the largest difference in those approximations. The corresponding bounds are set in the bounds for that coefficient passed to the Octave function *schurOneMPAlattice_socp_mmse*. The results of this MMSE optimisation are then passed to *schurOneMPAlattice_slb* for PCLS optimisation. The resulting PCLS coefficient value selects the closer of the upper or lower signed-digit values as the final choice for that coefficient. The truncation of the last coefficient is, by necessity, not PCLS optimised so the final set of coefficients may not meet the PCLS specifications.

The signed-digit lattice coefficients found by the heuristic of *Lim et al.* are:

```
A1k_sd = [ 1576,      -176,      -548,      -130, ...
           -121,       501,     -296,        -9, ...
            337,      -328,      128 ]'/2048;
A2k_sd = [  796,      -560,      382,      335, ...
           -95,        80,     -416,      368, ...
            8,      -368,      304,     -113 ]'/2048;
```

The signed-digit lattice coefficients found by the SOCP-relaxation search are:

```
A1k_min = [ 1576,      -184,      -548,      -133, ...
           -111,       494,     -296,        -6, ...
            337,      -328,      128 ]'/2048;
A2k_min = [  792,      -558,      380,      330, ...
           -94,        80,     -400,      368, ...
            4,      -368,      312,     -125 ]'/2048;
```

The signed-digit lattice coefficients found by the SOCP-relaxation search are implemented with 68 signed-digits and 45 shift-and-add operations.

Figure 15.8 shows the amplitude and group-delay pass-band responses of the filter with 12-bit 3-signed-digit coefficients allocated with the algorithm of *Lim et al.* and SOCP-relaxation search. Figure 15.9 shows the corresponding filter stop-band amplitude response. Table 15.4 compares the cost and the number of 12 bit shift-and-add operations required to implement the coefficient multiplications found by the signed-digit allocation heuristic of *Lim et al.* with the SOCP-relaxation search.

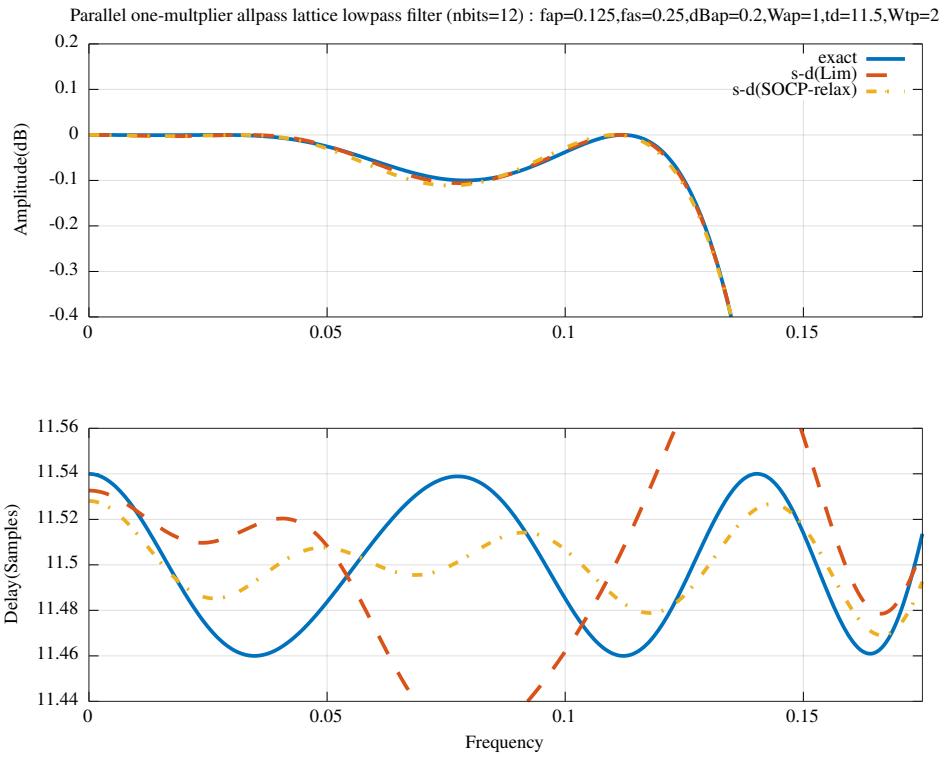

Figure 15.8: Amplitude and group-delay pass-band responses for a parallel Schur one-multiplier all-pass lattice low-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SOCP-relaxation search.

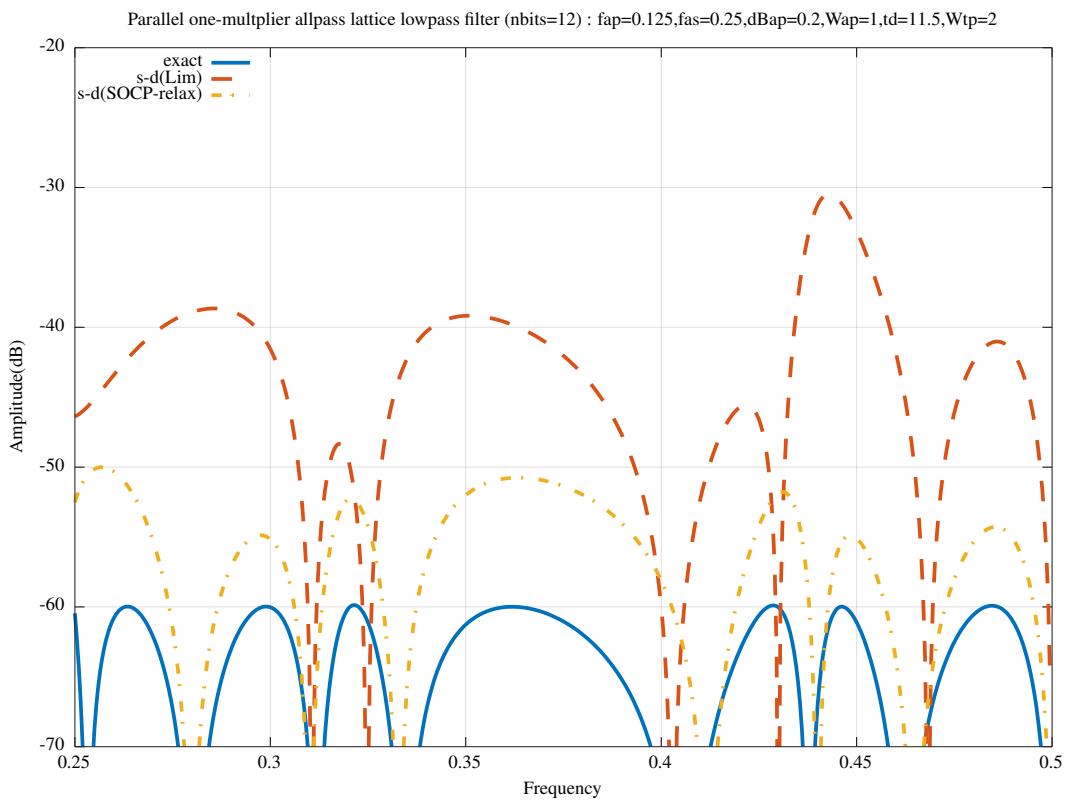

Figure 15.9: Amplitude stop-band responses for a parallel Schur one-multiplier all-pass lattice low-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SOCP-relaxation search.

	Cost	Signed-digits	Shift-and-adds
Exact	0.001818		
12-bit 3-signed-digit(Lim)	0.005382	67	44
12-bit 3-signed-digit(SOCP-relax)	0.000591	68	45

Table 15.4: Comparison of the cost and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for a parallel Schur one-multiplier all-pass lattice low-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SOCP-relaxation search.

15.5 SOCP-relaxation search for the signed-digit coefficients of a parallel all-pass lattice band-pass IIR filter

The Octave script `socp_relaxation_schurOneMPAlattice_bandpass_12_nbites_test.m` performs successive SOCP relaxations to optimise the response of the parallel Schur one-multiplier all-pass lattice band-pass filter of Section 10.3.7 with 12-bit integer coefficients. The filter specification is:

```
socp_relaxation_schurOneMPAlattice_bandpass_12_nbites_test_allocsd_Lim=1
socp_relaxation_schurOneMPAlattice_bandpass_12_nbites_test_allocsd_Ito=0
nbites=12 % Coefficient word length
ndigits=3 % Average number of signed digits per coef.
tol=0.0001 % Tolerance on coefficient update vector
ctol=1e-05 % Tolerance on constraints
n=1000 % Frequency points across the band
difference=1 % Use difference of all-pass filters
m1=10 % Allpass model filter 1 denominator order
m2=10 % Allpass model filter 2 denominator order
rho=0.992188 % Constraint on allpass coefficients
fapl=0.1 % Pass band amplitude response lower edge
fapu=0.2 % Pass band amplitude response upper edge
dBap=2.000000 % Pass band amplitude response ripple(dB)
Wap=1 % Pass band amplitude response weight
Watl=0.1 % Lower transition band amplitude response weight
Watu=0.1 % Upper transition band amplitude response weight
fasl=0.05 % Stop band amplitude response lower edge
fasu=0.25 % Stop band amplitude response upper edge
dBas=40.000000 % Stop band amplitude response ripple(dB)
Wasl=2000 % Lower stop band amplitude response weight
Wasu=1000 % Upper stop band amplitude response weight
ftpl=0.09 % Pass band group-delay response lower edge
ftpu=0.21 % Pass band group-delay response upper edge
td=16.000000 % Pass band nominal group-delay response(samples)
tdr=0.200000 % Pass band group-delay response ripple(samples)
Wtp=2 % Pass band group-delay response weight
```

The filter coefficients are truncated to 12 bits allocated with an average of 3 signed-digits by the heuristic of *Lim et al.* as shown in Section 11.1. At each coefficient relaxation step the script finds the upper and lower signed-digit approximations to the current set of active coefficients and selects the coefficient with the largest difference in those approximations. The corresponding bounds are set in the bounds for that coefficient passed to the Octave function `schurOneMPAlattice_socp_mmse`. The results of this MMSE optimisation are then passed to `schurOneMPAlattice_slb` for PCLS optimisation. The resulting PCLS coefficient value selects the closer of the upper or lower signed-digit values as the final choice for that coefficient. The truncation of the last coefficient is, by necessity, not PCLS optimised so the final set of coefficients may not meet the PCLS specifications.

The signed-digit lattice coefficients found by the heuristic of *Lim et al.* are:

```
A1k_sd = [ -1570,      1775,       48,      -760, ...
           1158,     -224,        0,      880, ...
          -636,      312 ]'/2048;
A2k_sd = [ -905,      1696,       120,      -672, ...
           1116,     -392,     -376,      896, ...
          -580,      320 ]'/2048;
```

The signed-digit lattice coefficients found by the SOCP-relaxation search are:

```
A1k_min = [ -1529,      1729,       80,      -641, ...
            1218,     -448,        0,      760, ...
           -552,      312 ]'/2048;
A2k_min = [ -878,      1696,       127,      -532, ...
            1220,     -560,     -82,      752, ...
           -542,      320 ]'/2048;
```

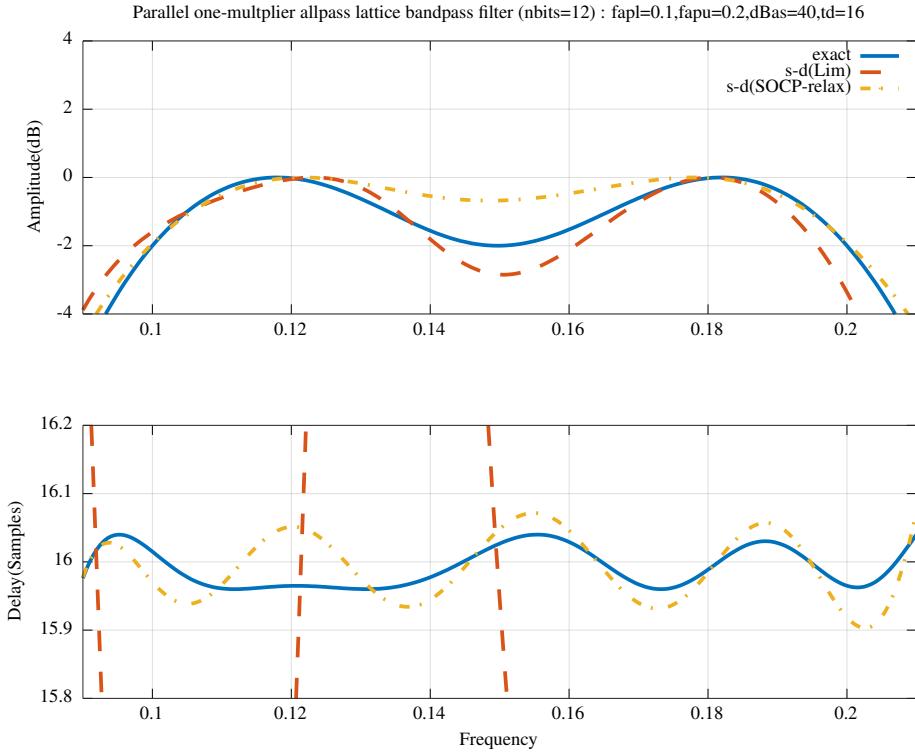

Figure 15.10: Amplitude and group-delay pass-band responses for a parallel Schur one-multiplier all-pass lattice band-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SOCP-relaxation search.

The signed-digit lattice coefficients found by the SOCP-relaxation search are implemented with 59 signed-digits and 40 shift-and-add operations.

Figure 15.10 shows the amplitude and group-delay pass-band responses of the filter with 12-bit 3-signed-digit coefficients allocated with the algorithm of *Lim et al.* and SOCP-relaxation search. Figure 15.11 shows the corresponding filter stop-band amplitude response. Table 15.5 compares the cost and the number of 12 bit shift-and-add operations required to implement the coefficient multiplications found by the signed-digit allocation heuristic of *Lim et al.* with the SOCP-relaxation search.

	Cost	Signed-digits	Shift-and-adds
Exact	0.033556		
12-bit 3-signed-digit(Lim)	2.876747	58	39
12-bit 3-signed-digit(SOCP-relax)	0.018050	59	40

Table 15.5: Comparison of the cost and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for a parallel Schur one-multiplier all-pass lattice band-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SOCP-relaxation search.

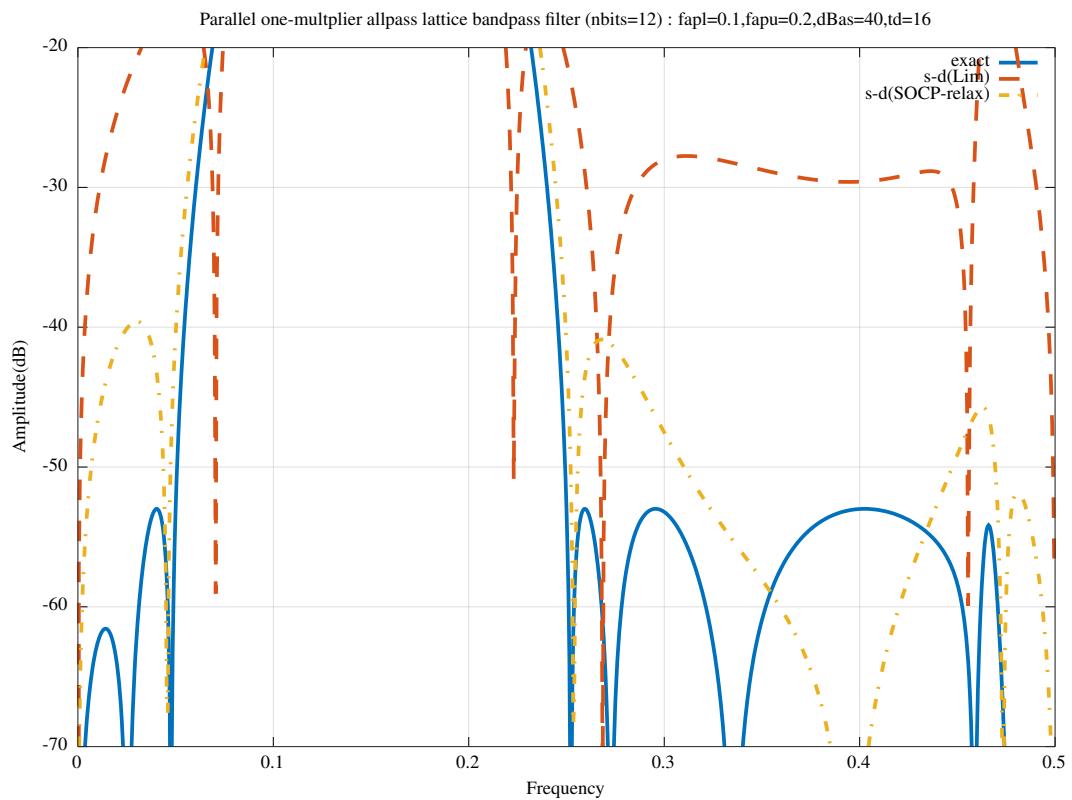

Figure 15.11: Amplitude stop-band responses for a parallel Schur one-multiplier all-pass lattice band-pass filter with 12 bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of Lim *et al.* and performing SOCP-relaxation search.

15.6 SOCP-relaxation search for the signed-digit coefficients of a lattice Hilbert IIR filter

The Octave script `socp_relaxation_schurOneMlattice_hilbert_10_nbis_test.m` performs successive SOCP relaxations to optimise the response of the band-pass Schur one-multiplier lattice filter of Section 10.3.4 with 10-bit integer coefficients. The filter specification is:

```
tol=1e-08 % Tolerance on coefficient update vector
ctol=1e-08 % Tolerance on constraints
n=400 % Frequency points across the band
rho=1.000000 % Constraint on lattice coefficient magnitudes
ft=0.05 % Transition band width [0,ft]
dBap=0.17 % Amplitude pass band peak-to-peak ripple
Wat=1e-08 % Amplitude transition band weight
Wap=1 % Amplitude pass band weight
tp=5.5 % Nominal pass band filter group delay (samples)
pr=0.011 * pi % Phase pass band peak-to-peak ripple (rad.)
Wpp=1 % Phase pass band weight
```

The filter coefficients are truncated to 10 bits allocated with an average of 3 signed-digits by the heuristic of *Lim et al.* as shown in Section 11.1. In this example, the group delay response is not constrained. I did not succeed in finding a Hilbert filter with integer coefficients using the SQP solver or using the signed-digit allocation heuristic of *Ito et al.*.

As in Section 15.2, at each coefficient relaxation step the script finds the upper and lower signed-digit approximations to the current set of active coefficients and selects the coefficient with the largest difference in those approximations. The corresponding bounds are set in the bounds for that coefficient passed to the Octave function `schurOneMlattice_socp_mmse`. The results of this MMSE optimisation are then passed to `schurOneMlattice_slb` for PCLS optimisation. The resulting PCLS coefficient value selects the closer of the upper or lower signed-digit values as the final choice for that coefficient. The truncation of the last coefficient is, by necessity, not PCLS optimised so the final set of coefficients may not meet the PCLS specifications.

The signed-digit filter coefficients found by the heuristic of *Lim et al.* are:

```
k0_sd = [      0,      -468,      0,      284, ...
            0,      -49,       0,       0, ...
            0,      -1,       0,       1 ]'/512;

c0_sd = [     22,       26,     124,     148, ...
           96,     146,     351,    -303, ...
          -84,     -40,     -22,     -12, ...
          -8 ]'/512;
```

The signed-digit filter coefficients found by the SOCP-relaxation search are:

```
k_min = [      0,      -468,      0,      284, ...
            0,      -50,       0,       0, ...
            0,      -1,       0,       1 ]'/512;

c_min = [     22,       26,     124,     148, ...
           96,     146,     351,    -303, ...
          -84,     -41,     -23,     -12, ...
          -9 ]'/512;
```

Figure 15.12 compares the amplitude, group delay and phase responses of the filter with exact, 10-bit signed-digit coefficients allocated with the algorithm of *Lim et al.* and 10-bit signed-digit coefficients allocated with the algorithm of *Lim et al.* and SOCP-relaxation search. The phase response shown is adjusted to allow for the filter group-delay and then scaled by π . Table 15.6 compares the cost, the number of signed-digits and the number of 10-bit shift-and-add operations required to implement the coefficient multiplications found by the signed-digit allocation heuristic of *Lim et al.* with SOCP-relaxation search.

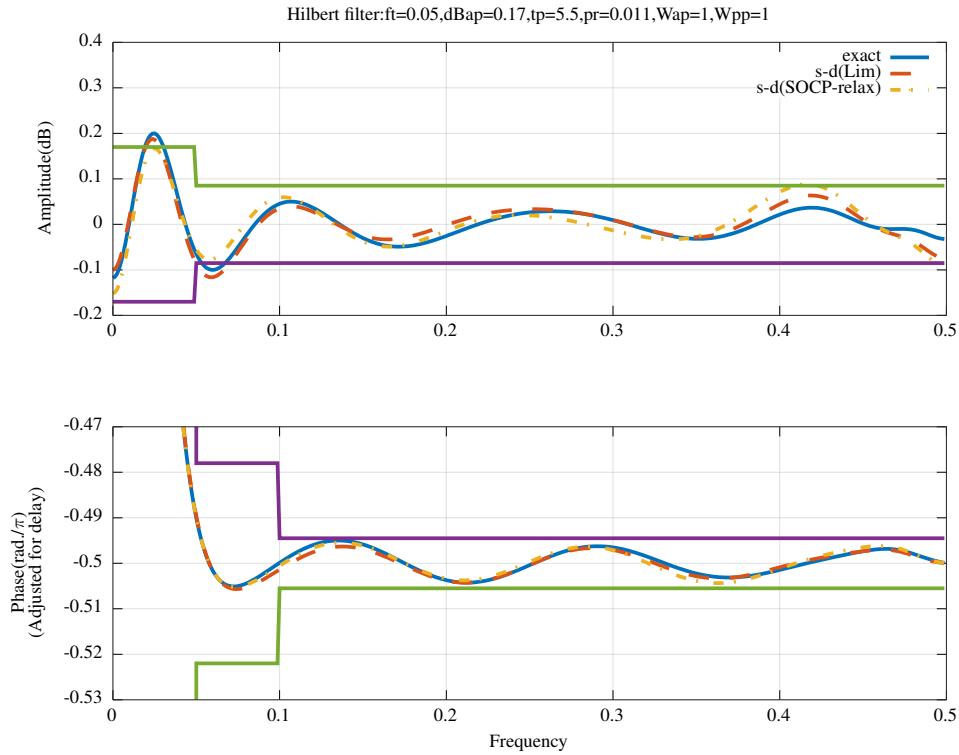

Figure 15.12: Comparison of the amplitude, group delay and phase responses for a Schur one-multiplier lattice Hilbert filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SOCP-relaxation search. The phase response shown is adjusted to allow for the filter group-delay and then scaled by π .

	Cost	Signed-digits	Shift-and-adds
Exact	0.000161		
10-bit 3-signed-digit(Lim)	0.000218	47	29
10-bit 3-signed-digit(SOCP-relax)	0.000259	48	30

Table 15.6: Comparison of the cost and number of 10-bit shift-and-add operations required to implement the coefficient multiplications for a Schur one-multiplier lattice Hilbert filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SOCP-relaxation search.

15.7 SOCP relaxation search for the 12-bit 3-signed-digit coefficients of a FRM low-pass filter

The Octave script *socp_relaxation_schurOneMAPlattice_frm_12_nbis_test.m* uses socp-relaxation search to optimise the response of the FRM low-pass filter of Section 10.4.6 with 12-bit coefficients each having an average of 3 signed-digits allocated by the method of *Ito et al.*. The number of signed-digits per coefficient is as shown in Section 14.10. The filter specification is:

```
n=1000 % Frequency points across the band
tol=0.0001 % Tolerance on coefficient update vector
ctol=1e-05 % Tolerance on constraints
n=1000 % Frequency points across the band
mr=10 % Allpass model filter denominator order
Mmodel=9 % Model filter FRM decimation factor
Dmodel=9 % Model filter nominal pass band group delay
dmask=20 % FIR masking filter delay
fap=0.3 % Magnitude-squared pass band edge
dBap=0.1 % Pass band magnitude peak-to-peak ripple
Wap=1 % Pass band magnitude-squared weight
fas=0.3105 % Magnitude-squared stop band edge
dBas=37 % Stop band magnitude minimum attenuation
Was=10 % Stop band magnitude-squared weight
ftp=0.3 % Delay pass band edge
tp=101 % Pass band nominal delay
tpr=tp/101 % Pass band delay peak-to-peak ripple
Wtp=1 % Pass band magnitude-squared weight
fpp=0.3 % Phase pass band edge
ppr=0.02*pi % Pass band phase peak-to-peak ripple (rad.)
Wpp=0.1 % Phase pass band weight
rho=0.992188 % Constraint on allpass pole radius
```

The filter coefficients found by the socp-relaxation search are:

```
k_min = [ -32,      1184,       36,      -292, ...
           -8,        113,        18,       -55, ...
          -10,        16 ]'/2048;

epsilon_min = [ 1,   1,  -1,   1, ...
                1,  -1,  -1,   1, ...
                1,  -1 ];

u_min = [ 1168,      620,     -128,     -176, ...
           104,        69,      -88,       -8, ...
            72,      -24,      -32,      28, ...
           20,      -18,       -8,      16, ...
           -2,      -16,        8,        4, ...
           -9 ]'/2048;

v_min = [ -1362,     -560,      275,        8, ...
           -132,       100,         7,      -68, ...
            56,        -2,      -36,      32, ...
             4,       -21,       16,        4, ...
           -14,        12,      -4,      -4, ...
             5 ]'/2048;
```

Figure 15.13, compares the amplitude, delay and phase responses of the FRM low-pass filter with exact and 12-bit coefficients with an average of 3-signed-digits allocated by the method of *Ito et al.* and with the coefficients found by SOCP-relaxation search. Table 15.7 compares the cost and the number of 12 bit shift-and-add operations required to implement the coefficient multiplications found by SOCP-relaxation search.

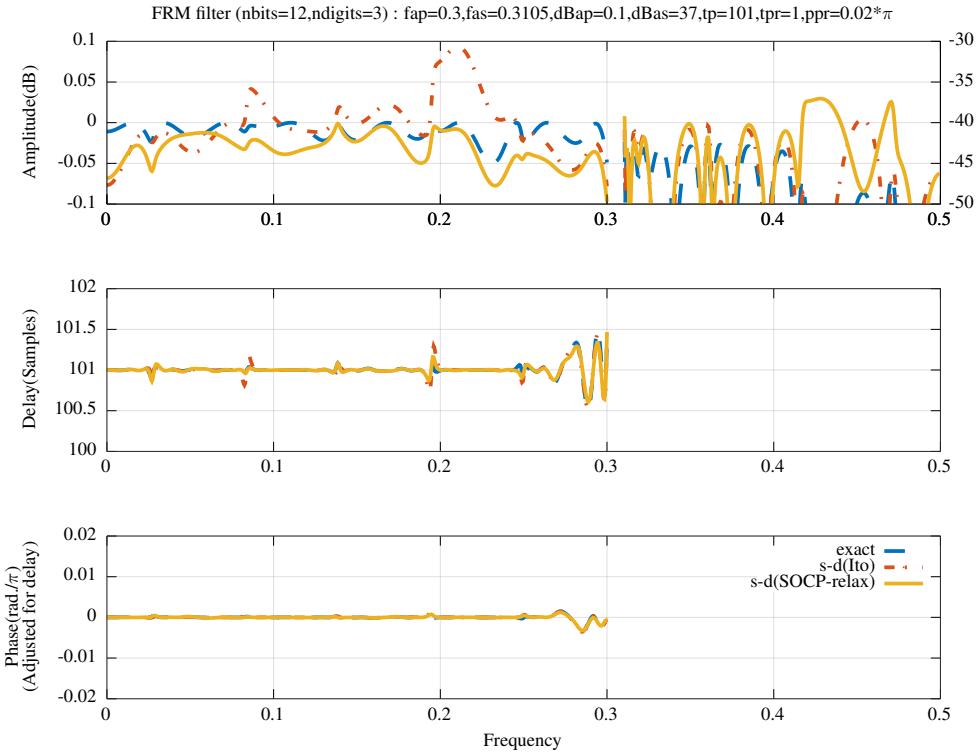

Figure 15.13: Comparison of the amplitude, delay and phase responses of an FRM low-pass filter with exact and 12 bit coefficients with an average of 3-signed-digits allocated by the method of *Ito et al.* and with the coefficients found by SOCP-relaxation search

	Cost	Signed-digits	Shift-and-adds
Exact	0.001537		
12-bit 3-signed-digit(Ito)	0.001799	101	49
12-bit 3-signed-digit(SOCP-relax)	0.001222	103	51

Table 15.7: Comparison of the cost and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for an FRM low-pass filter with 12-bit coefficients with an average of 3-signed-digits allocated by the method of *Ito et al.* and with the coefficients found by SOCP-relaxation search

15.8 SOCP-relaxation search for the signed-digit coefficients of an FRM Hilbert IIR filter with an all-pass lattice model filter

The Octave script `socp_relaxation_schurOneMAPlattice_frm_hilbert_12_nbits_test.m` performs successive SOCP relaxations to optimise the response of the FRM Hilbert filter of Section 10.4.8 with 12-bit integer coefficients. The FRM model model filter is implemented as a Schur one-multiplier all-pass lattice filter. The filter specification is:

```
n=800 % Frequency points across the band
tol=5e-05 % Tolerance on coefficient update vector
ctol=5e-05 % Tolerance on constraints
n=800 % Frequency points across the band
mr=5 % Allpass model filter denominator order
Mmodel=7 % Model filter FRM decimation factor
Dmodel=9 % Model filter nominal pass band group delay
dmask=16 % FIR masking filter delay
fap=0.01 % Magnitude-squared pass band edge
fas=0.49 % Magnitude-squared stop band edge
dBap=0.22 % Pass band magnitude-squared peak-to-peak ripple
Wap=1 % Pass band magnitude-squared weight
ftp=0.01 % Delay pass band edge
fts=0.49 % Delay stop band edge
tp=79 % Pass band nominal delay
tpr=tp/50 % Pass band delay peak-to-peak ripple
Wtp=1 % Pass band magnitude-squared weight
fpp=0.01 % Phase pass band edge
fps=0.49 % Phase stop band edge
pp=-0.5*pi % Pass band nominal phase (rad.)
ppr=0.01*pi % Pass band phase peak-to-peak ripple (rad.)
Wpp=0.005 % Phase pass band weight
```

The filter coefficients are truncated to 12 bits allocated with an average of 2 signed-digits by the heuristic of *Lim et al.* shown in Section 11.1.

As in Section 15.2, at each coefficient relaxation step the script finds the upper and lower signed-digit approximations to the current set of active coefficients and selects the coefficient with the largest difference in those approximations. The corresponding filter is PCLS optimised by the function `schurOneMAPlattice_frm_hilbert_slb`. The resulting PCLS coefficient value selects the nearer of the upper or lower signed-digit values as the final choice for that coefficient. The truncation of the last coefficient is necessarily not PCLS optimised so the final set of coefficients may not meet the PCLS specifications.

The signed-digit filter coefficients found by the heuristic of *Lim et al.* are:

```
k0_sd = [ -1152,      -272,      -112,      -32, ...
           -16 ]'/2048;

u0_sd = [      -2,       -4,      -15,      -24, ...
           -64,      -72,     -104,     -116, ...
          901 ]'/2048;

v0_sd = [      16,        9,      15,        4, ...
           -16,     -64,     -168,    -644 ]'/2048;
```

The signed-digit filter coefficients found by the SOCP-relaxation search are:

```
k_min = [ -1152,      -272,      -112,      -32, ...
           -16 ]'/2048;

u_min = [      -1,       -4,      -14,      -24, ...
           -64,      -72,     -104,     -116, ...
          901 ]'/2048;
```

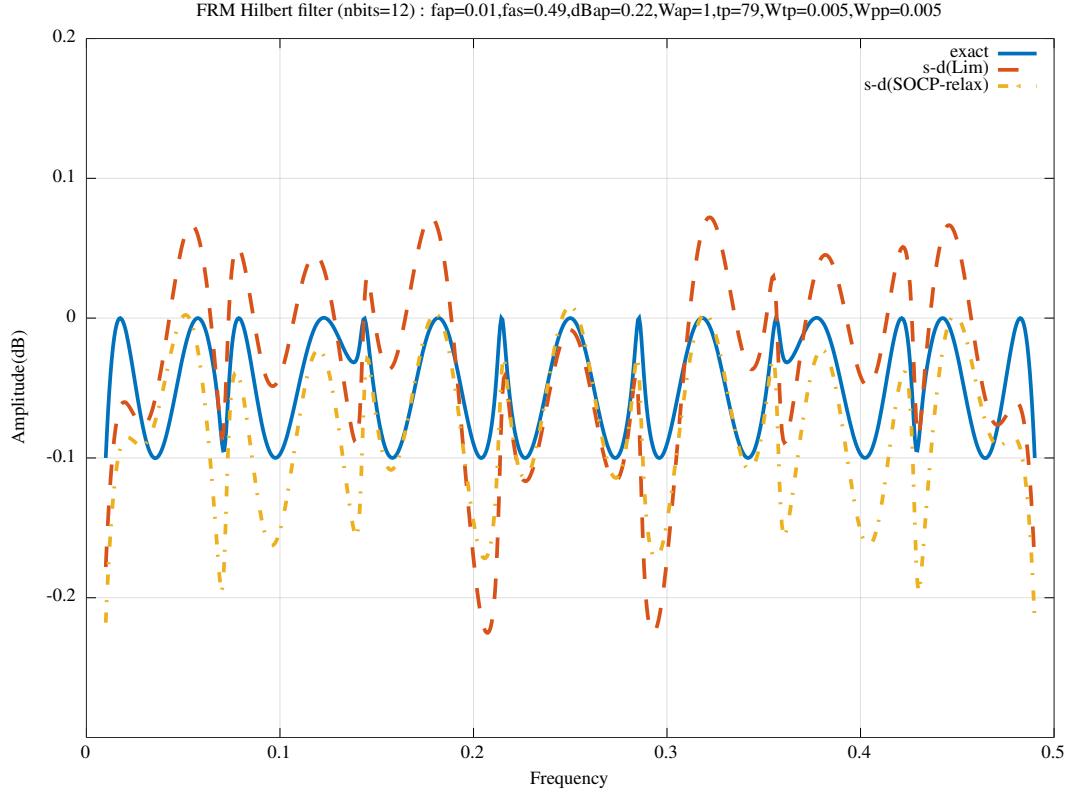

Figure 15.14: Comparison of the amplitude responses for an FRM Hilbert filter with 12 bit integer coefficients found by allocating an average of 2 signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SOCP-relaxation search. The FRM model filter is implemented as a Schur one-multiplier all-pass lattice filter.

```
v_min = [      16,      10,      14,      4, ...
           -16,     -64,    -164,   -641 ]'/2048;
```

Table 15.8 compares the cost, the number of signed-digits and the number of 12-bit shift-and-add operations required to implement the coefficient multiplications found by the signed-digit allocation heuristic of *Lim et al.* optimised by SOCP-relaxation search. The one-multiplier lattice implementation requires a further 15 additions (3 per coefficient) and the FIR masking filter requires a further 33 additions. Figures 15.14, 15.15 and 15.16 compare the amplitude, delay and phase responses of the filter with exact, 12 bit 2 signed-digit coefficients allocated with the algorithm of *Lim et al.* and 12-bit 2-signed-digit coefficients allocated with the algorithm of *Lim et al.* and optimised by SOCP-relaxation search. The phase response is adjusted for the nominal delay and normalised to π radians.

	Cost	Signed-digits	Shift-and-adds
Exact	0.000656		
12-bit 2-signed-digit(Lim)	0.001206	41	19
12-bit 2-signed-digit(SOCP-relax)	0.001701	41	19

Table 15.8: Comparison of the cost and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for an FRM Hilbert filter with 12 bit integer coefficients found by allocating an average of 2 signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SOCP-relaxation search. The FRM model filter is implemented as a Schur one-multiplier all-pass lattice filter.

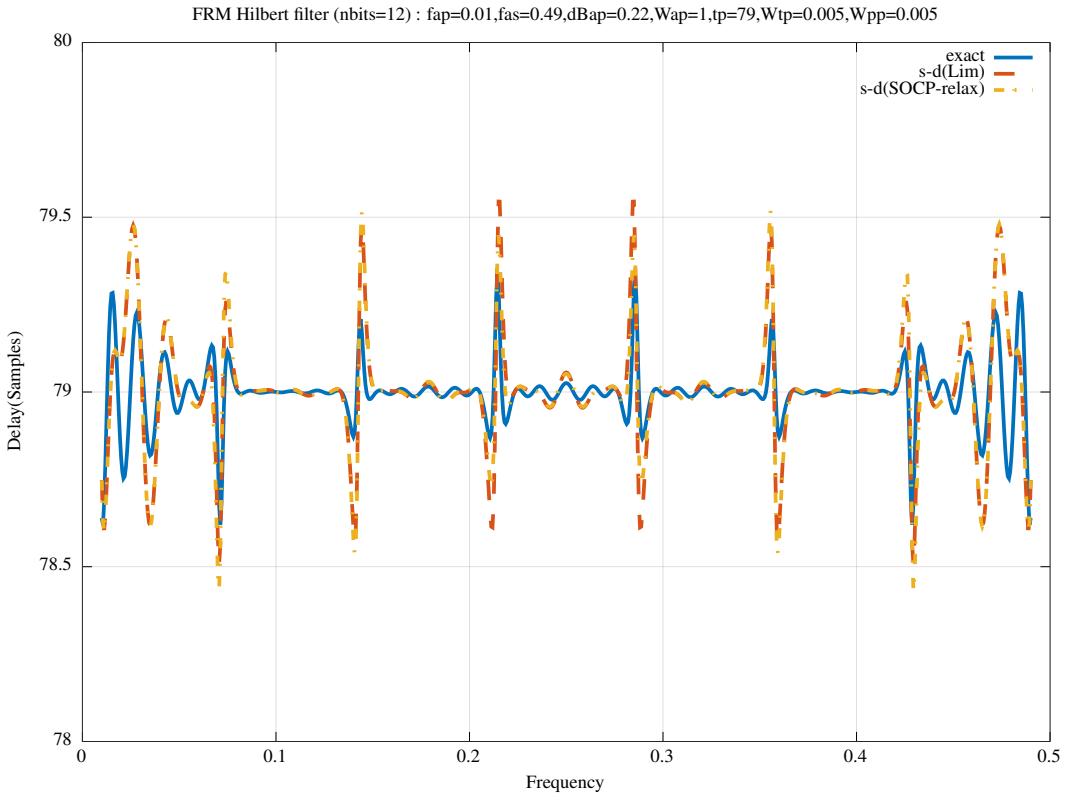

Figure 15.15: Comparison of the delay responses for an FRM Hilbert filter with with 12 bit integer coefficients found by allocating an average of 2 signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SOCP-relaxation search. The FRM model model filter is implemented as a Schur one-multiplier all-pass lattice filter.

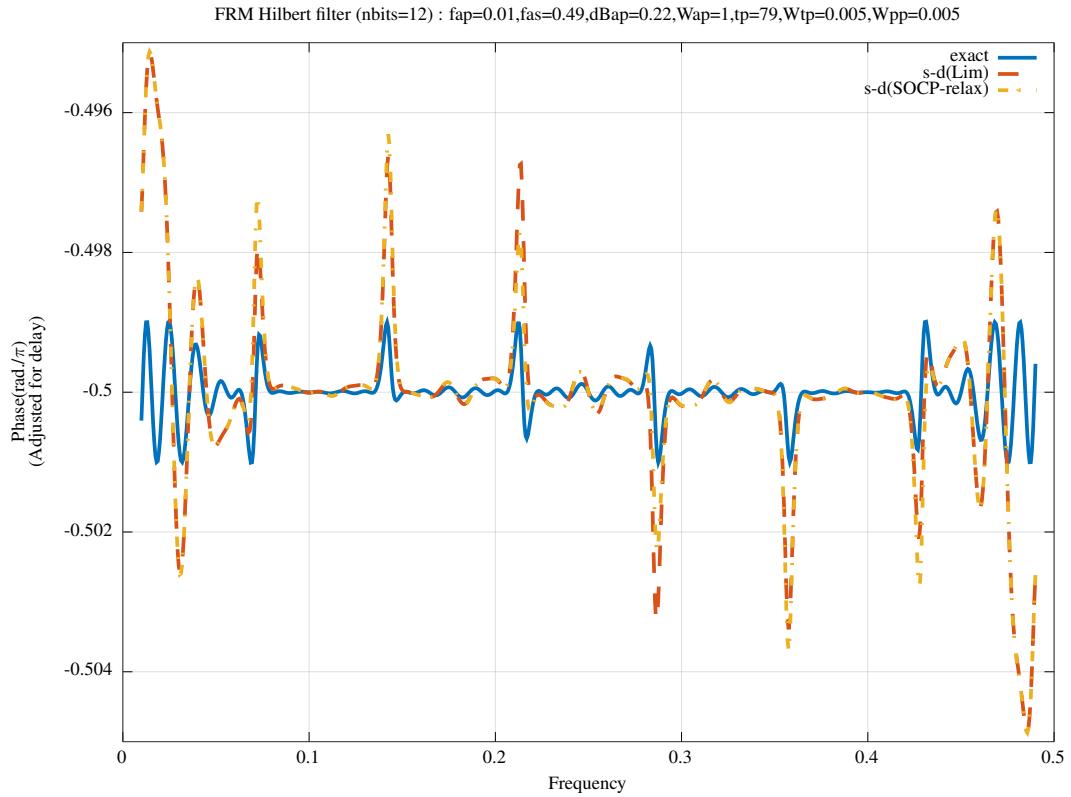

Figure 15.16: Comparison of the phase responses for an FRM Hilbert filter with with 12 bit integer coefficients found by allocating an average of 2 signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SOCP-relaxation search. The FRM model model filter is implemented as a Schur one-multiplier all-pass lattice filter.

15.9 SOCP-relaxation search for the signed-digit coefficients of a direct-form FIR Hilbert filter

The Octave script *socp_relaxation_directFIRhilbert_12_nbites_test.m* performs successive SOCP relaxations to optimise the response of a direct-form FIR Hilbert filter having a response similar to that of Section 15.8. The filter specification is:

```
nbits=12 % Coefficient bits
ndigits=2 % Nominal average coefficient signed-digits
tol=1e-05 % Tolerance on coef. update
ctol=1e-05 % Tolerance on constraints
maxiter=1000 % SOCP iteration limit
npoints=500 % Frequency points across the band
fapl=0.01 % Amplitude pass band lower edge
fapu=0.49 % Amplitude pass band upper edge
dBap=0.135 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
Was=0 % Amplitude stop band weight
```

The nominal filter polynomial order is 160, the filter group-delay is 80 samples and the filter has 40 distinct non-zero coefficients. The filter coefficients are truncated to 12 bits allocated with an average of 2 signed-digits by the heuristic of *Ito et al.*, as shown in Section 11.2. At each coefficient relaxation step the script finds the upper and lower signed-digit approximations to the current set of active coefficients and selects the coefficient with the largest difference in those approximations. The corresponding bounds are set in the bounds for that coefficient passed to the Octave function *directFIRhilbert_socp_mmse*. The results of this MMSE optimisation are then passed to *directFIRhilbert_slb* for PCLS optimisation. The resulting PCLS coefficient value selects the closer of the upper or lower signed-digit values as the final choice for that coefficient. The truncation of the last coefficient is, by necessity, not PCLS optimised so the final set of coefficients may not meet the PCLS specifications.

The 12-bit signed-digit filter coefficients found by the heuristic of *Ito et al.* are:

```
hM0_Ito_sd = [ 1304,      432,      258,      183, ...
                140,       112,       96,       80, ...
                 69,       60,       52,       48, ...
                 40,       36,       32,       28, ...
                 24,       24,       20,       20, ...
                 16,       16,       12,       12, ...

Figure 15.17 compares the amplitude responses of the filter with exact, 12-bit 2-signed-digit coefficients, 12-bit signed-digit coefficients allocated with the algorithm of *Ito et al.* and 12-bit signed-digit coefficients allocated with the algorithm of *Ito et al.* and SOCP-relaxation search. Table 15.9 compares the cost, the number of signed-digits and the number of 12-bit shift-and-add operations required to implement the coefficient multiplications found by the signed-digit allocation heuristic of *Ito et al.* with SOCP-relaxation search. The FIR filter structure requires an extra 80 additions.

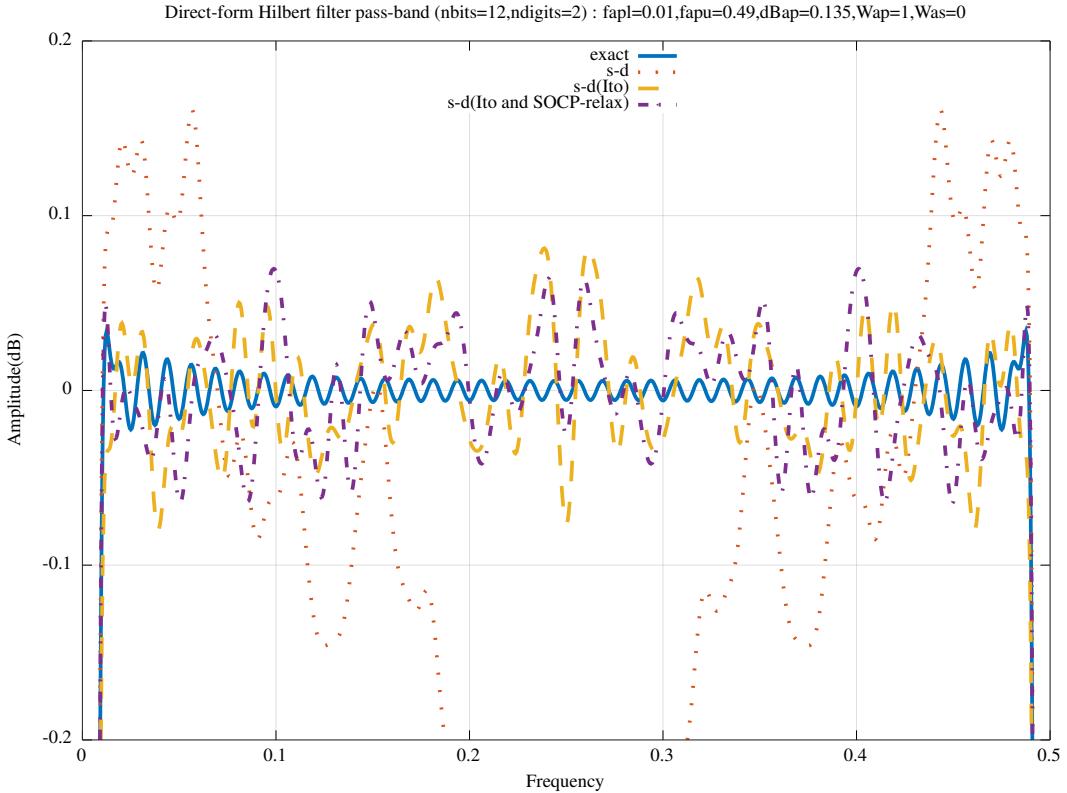

Figure 15.17: Comparison of the amplitude responses for a direct-form FIR Hilbert filter with 12-bit integer coefficients found by allocating an average of 2-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SOCP-relaxation search.

	Cost	Signed-digits	Shift-and-adds
Exact	4.778e-07		
12-bit 2-signed-digit	0.0002078	71	31
12-bit 2-signed-digit(Ito)	7.513e-06	72	32
12-bit 2-signed-digit(SOCP-relax)	6.676e-06	72	32

Table 15.9: Comparison of the cost and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for a direct-form FIR Hilbert filter with 12-bit integer coefficients found by allocating an average of 2-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SOCP-relaxation search.

15.10 POP relaxation search for the signed-digit coefficients of a one-multiplier lattice bandpass filter

Lu [84] and *Lu* and *Hinamoto* [162] point out that the integer programming optimisation of the truncated filter coefficients shown in Equation 16.1 can be rewritten as a *polynomial optimisation problem* (POP) in SOCP form as:

$$\begin{aligned} \text{minimise} \quad & \mathcal{E}(\mathbf{x}_k) + \nabla_x \mathcal{E}(\mathbf{x}_k)^T \Delta \mathbf{x} + \frac{1}{2} \Delta \mathbf{x}^T \nabla_{xx}^2 \mathcal{E}(\mathbf{x}_k) \Delta \mathbf{x} \\ \text{subject to} \quad & (\mathbf{x}_k + \Delta \mathbf{x} - \mathbf{x}_u)^T (\mathbf{x}_k + \Delta \mathbf{x} - \mathbf{x}_l) = 0 \end{aligned}$$

where $\Delta \mathbf{x}$ is the coefficient update vector, \mathcal{E} is the weighted response error at \mathbf{x}_k and \mathbf{x}_u and \mathbf{x}_l are the upper and lower bounds on the truncated coefficients, $\mathbf{x}_k + \Delta \mathbf{x}$.

Lasserre [67] and *Waki et al.* [53] show that polynomial optimisation can be reduced to the solution of “an often finite sequence of convex linear matrix inequality problems”. *Waki et al.* have written *SparsePOP* [54], a “Matlab implementation of sparse semidefinite programming (SDP) relaxation for polynomial optimization problems”. SparsePOP runs under Octave with minor modifications. SparsePOP converts the POP problem to a larger SOCP problem that is solved by SeDuMi.

The Octave script *pop_relaxation_schurOneMlattice_bandpass_10_nbites_test.m* performs SparsePOP optimisation of the truncated coefficients of the SQP optimised band-pass Schur one-multiplier lattice filter described in Section 10.3.3. The filter specification is:

```
nbits=10 % Coefficient bits
ndigits=3 % Nominal average coefficient signed-digits
tol=0.0001 % Tolerance on coef. update
ctol=0.0001 % Tolerance on constraints
maxiter=2000 % SOCP iteration limit
npoints=250 % Frequency points across the band
length(c0)=21 % Num. tap coefficients
sum(k0~=0)=10 % Num. non-zero all-pass coef.s
rho=0.998047 % Constraint on allpass coefficients
fapl=0.1 % Amplitude pass band lower edge
fapu=0.2 % Amplitude pass band upper edge
dBap=2 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
ftpl=0.09 % Delay pass band lower edge
ftpu=0.21 % Delay pass band upper edge
tp=16 % Nominal passband filter group delay
tpr=0.2 % Delay pass band peak-to-peak ripple
Wtp=5 % Delay pass band weight
fasl=0.05 % Amplitude stop band(1) lower edge
fasu=0.25 % Amplitude stop band(1) upper edge
dBas=33 % Amplitude stop band(1) peak-to-peak ripple
fasll=0.04 % Amplitude stop band(2) lower edge
fasuu=0.26 % Amplitude stop band(2) upper edge
dBass=36 % Amplitude stop band(2) peak-to-peak ripple
Wasl=100000 % Amplitude lower stop band weight
Wasu=1000000 % Amplitude upper stop band weight
```

The filter coefficients are truncated to 10 bits allocated with an average of 3 signed-digits by the heuristic of *Ito et al.* as shown in Section 11.2. At each coefficient relaxation step the script finds the upper and lower signed-digit approximations to the current set of active coefficients, selects the coefficient with the largest difference in those approximations and performs two optimisations. The first is an SOCP PCLS optimisation of the response with the current set of active coefficients. The second optimisation calls *SparsePOP* with a 2nd order polynomial equality constraint requiring that the previously selected coefficient be equal to either the signed-digit coefficient upper or lower bound. The remaining active coefficients are allowed to vary within the corresponding signed-digit upper and lower bounds. *SparsePOP* failed when I attempted to apply linear constraints on the response for PCLS optimisation (see *schurOneMlattice_pop_socp_mmse_test.m*).

The filter coefficients found by the SparsePOP relaxation search are:

```
k_min = [
    0,      336,      0,      256, ...
    0,      176,      0,      216, ...
    0,      148,      0,      128, ...
    0,      77,       0,      54, ...
    0,      19,       0,      9 ]'/512;
```

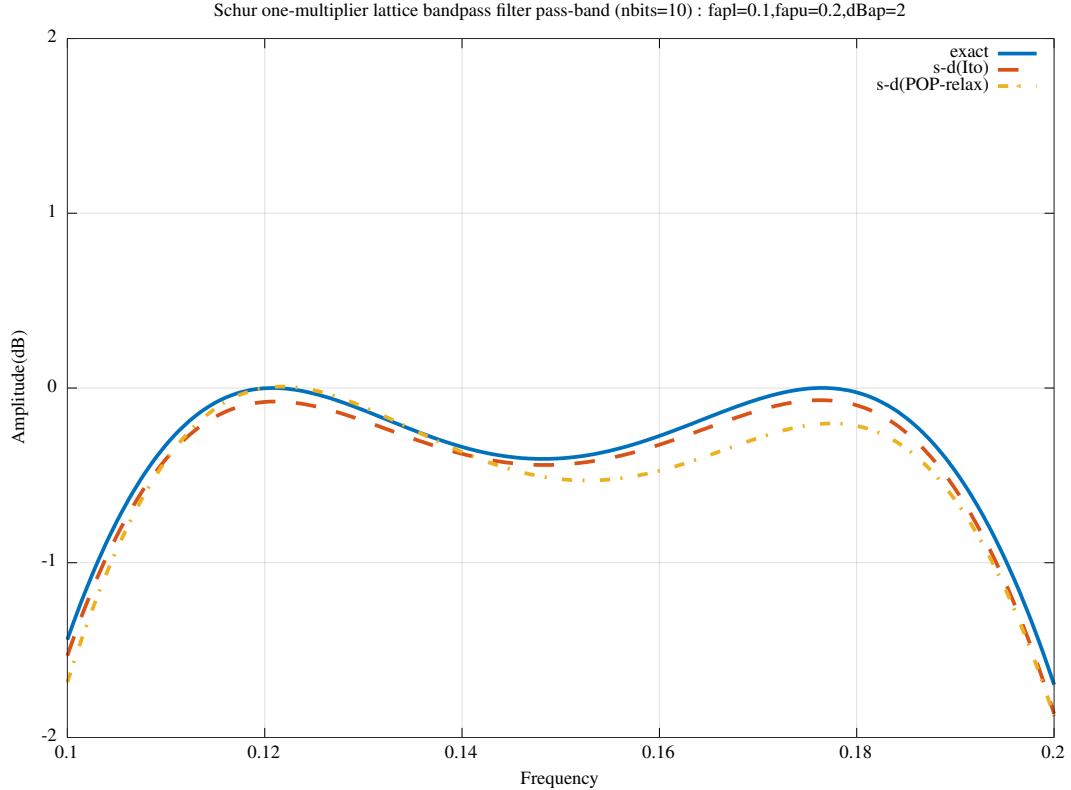

Figure 15.18: Comparison of the pass-band amplitude responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing POP-relaxation search

```
c_min = [      36,      -8,     -156,    -248, ...
           -82,      63,     200,     152, ...
             8,     -42,     -40,      -8, ...
            -4,     -16,     -12,       3, ...
           14,       8,       1,       0, ...
           2 ] '/512;
```

Table 15.10 compares the cost, the number of signed-digits and the number of 10-bit shift-and-add operations required to implement the coefficient multiplications found by the signed-digit allocation heuristic of *Ito et al.* and optimised by POP-relaxation search. Figure 15.18 compares the pass-band responses of the filter with exact and 10-bit coefficients allocated an average of 3-signed-digits found by the heuristic of *Ito et al.* and optimised by POP-relaxation search. Similarly, Figure 15.19 shows the filter stop-band response and Figure 15.20 shows the filter pass-band group delay response.

	Cost	Signed-digits	Shift-and-adds
Exact	0.0137		
10-bit 3-signed-digit(Ito)	0.0680	64	33
10-bit 3-signed-digit(POP-relax)	0.0258	63	33

Table 15.10: Comparison of the cost and number of 10-bit shift-and-add operations required to implement the coefficient multiplications for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing POP-relaxation search.

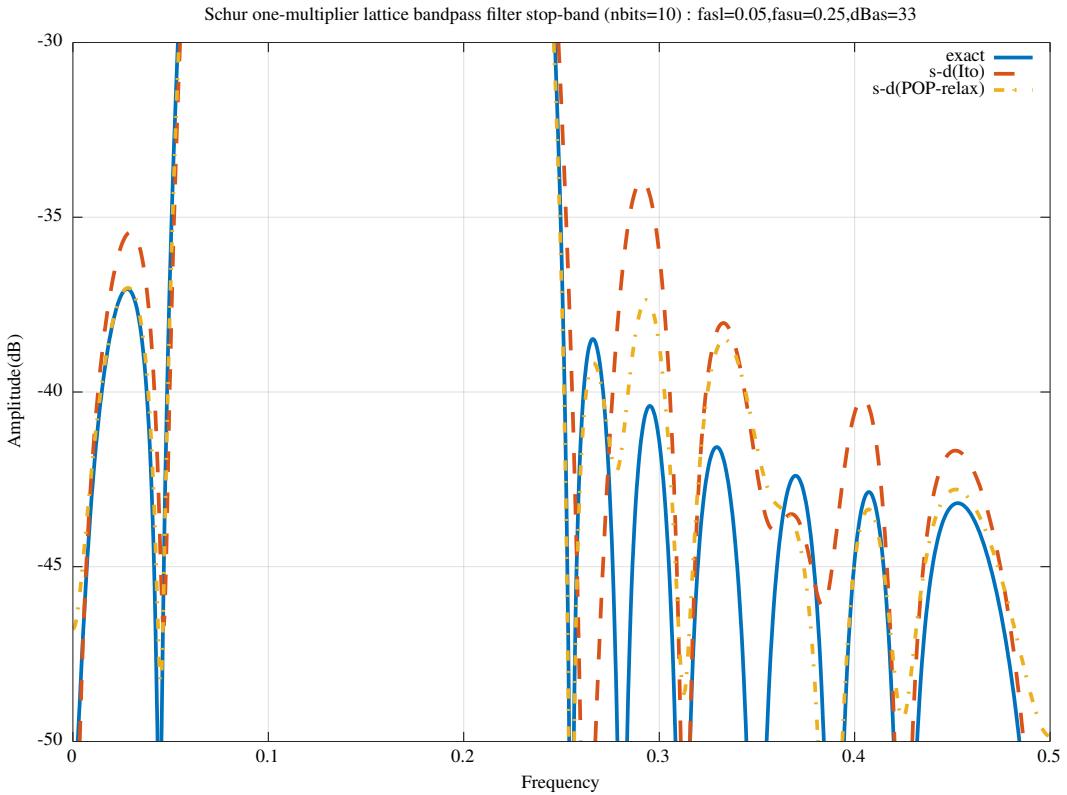

Figure 15.19: Comparison of the stop-band amplitude responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing POP-relaxation search

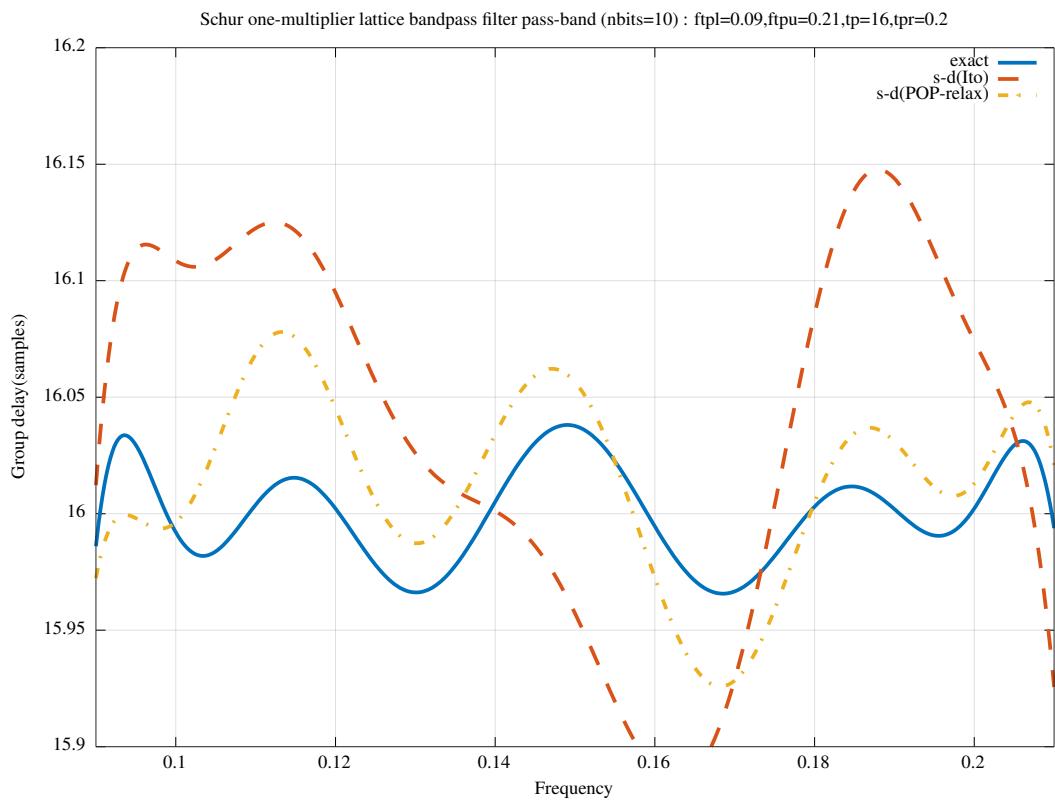

Figure 15.20: Comparison of the pass-band group delay responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing POP-relaxation search

15.11 SOCP-relaxation search for the signed-digit coefficients of a lattice FIR filter

The Gaussian function in the continuous angular frequency domain is:

$$G(\omega) = e^{-(\frac{\omega}{\alpha})^2}$$

Appendix J shows that the corresponding time domain Fourier transform pair function is:

$$g(t) = \frac{\alpha}{2\sqrt{\pi}} e^{-(\frac{t\alpha}{2})^2}$$

If the symbol interval is T_S then the normalised one-sided half-power bandwidth-symbol time product, BT_S , is given by:

$$e^{-\left(\frac{2\pi BT_S}{T_S \alpha}\right)^2} = \frac{1}{\sqrt{2}}$$

so:

$$\alpha = \frac{2\pi BT_S}{T_S} \sqrt{\frac{2}{\ln 2}}$$

Assume that the Gaussian filter has a length of N_S symbols and an over-sampling rate of R samples per symbol. After shifting and truncation the sampled filter coefficients of an odd length filter are:

$$g(k) = \frac{T_S}{R} \frac{1}{2\sqrt{\pi}} \frac{2\pi BT_S}{T_S} \sqrt{\frac{2}{\ln 2}} e^{-\left[\left(\frac{\pi BT_S}{T_S} \sqrt{\frac{2}{\ln 2}}\right) \frac{T_S}{R} \left(k - \frac{RN_S}{2}\right)\right]^2}$$

where $k = 0 \dots RN_S$. Assume that the modulation scheme uses $BT_S = 0.3$, that the Gaussian filter has a length of $N_S = 4$ symbols and that the over-sampling rate is $R = 8$ samples per symbol. The filter coefficients are:

```
g0= = [ 0.000003984, 0.000013788, 0.000044042, 0.000129853, ...
0.000353389, 0.000887708, 0.002058274, 0.004405067, ...
0.008701970, 0.015867136, 0.026705172, 0.041486623, ...
0.059488999, 0.078737407, 0.096192548, 0.108471994, ...
0.112904093, 0.108471994, 0.096192548, 0.078737407, ...
0.059488999, 0.041486623, 0.026705172, 0.015867136, ...
0.008701970, 0.004405067, 0.002058274, 0.000887708, ...
0.000353389, 0.000129853, 0.000044042, 0.000013788, ...
0.000003984 ]';
```

Figure 15.21 shows the impulse response of the filter.

The Octave script *socp_relaxation_schurFIRlattice_gaussian_16_nbts_test.m* performs SOCP relaxation to find the 16-bit coefficients of the Gaussian filter implemented as a complementary FIR lattice. (See Appendix L.1 for a description of the complementary FIR lattice filter). The response of this filter is compared with filters using 16-bit 3-signed-digit coefficients of the direct form implementation and the 16-bit signed-digit coefficients of the lattice implementation. The coefficients of the lattice filters are allocated an average of 3-signed-digits with the algorithm of Lim *et al.* shown in Section 11.2. The script does not implement signed-digit allocation or SOCP-relaxation optimisation of the direct-form coefficients. The filter specification is:

```
BTs=0.3 % Bandwidth-Symbol-rate product
Ns=4 % Filter width in symbols
R=8 % Samples-per-symbol
tol=1e-08 % Tolerance on coefficient update vector
ctol=1e-08 % Tolerance on constraints
nplot=1024 % Frequency points across the band
dBap=0.175 % Amplitude pass band peak-to-peak ripple
dBas=50 % Amplitude stop band peak-to-peak ripple
dBasu=63 % Amplitude upper stop band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
Was=1e+06 % Amplitude stop band weight
tp=16 % Nominal pass band filter group delay (samples)
tpr=0.4 % Delay pass band peak-to-peak ripple (rad.)
Wtp=0.01 % Delay pass band weight
```

The amplitude response in the “pass-band” (up to $dBas$) found by SOCP-relaxation is required to be within $\pm \frac{dBap}{2}$ of the exact response and below $dBasu$ in the “stop-band”.

The 16-bit 3-signed-digit direct form coefficients are:

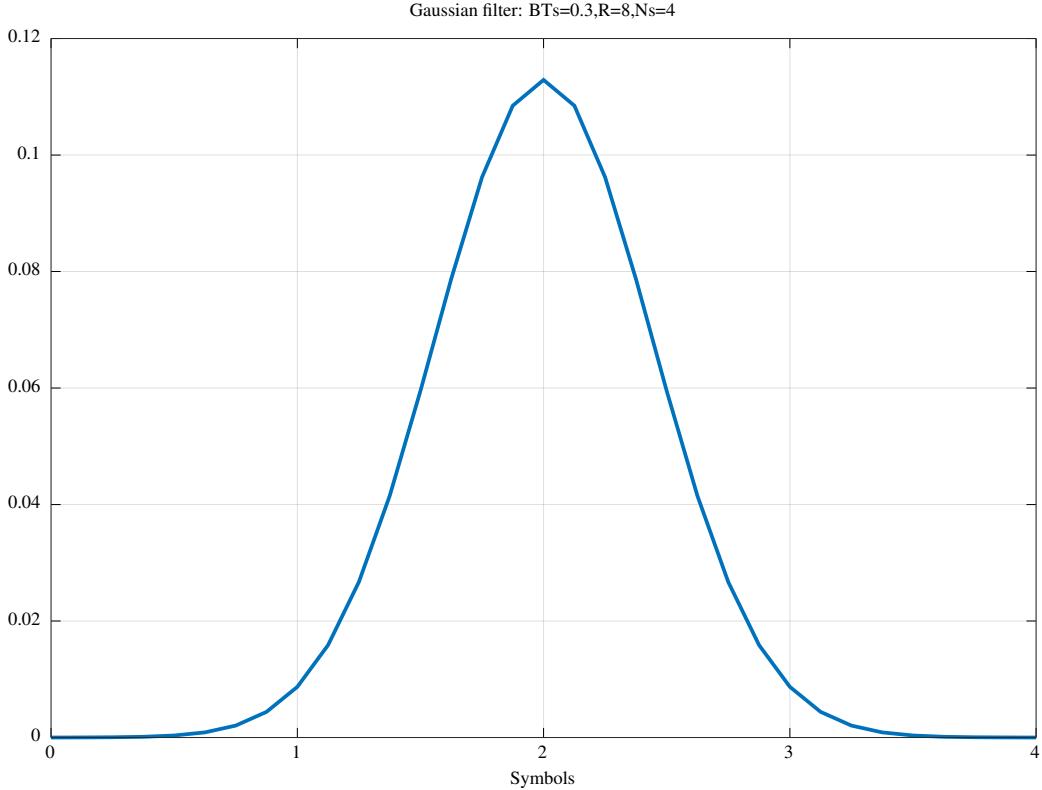

Figure 15.21: Impulse response of a sampled Gaussian filter with half-power bandwidth-symbol-interval product $BT_S = 0.3$, length $N_S = 4$ symbols and $R = 8$ samples per symbol

Table 15.11 compares the total number of signed-digits and 16-bit shift-and-add operations required to implement the coefficient multiplications. The values for the direct form filter assume that the implementation makes use of the symmetry of the impulse response, in which case the direct form filter has 17 multiplier scompared to the 130 required by the lattice implementation (though a number of the latter multipliers are 1 or 0).

	Signed-digits	Shift-and-adds
16-bit 3-signed-digit(direct-folded)	73	44
16-bit 3-signed-digit(lattice)	158	98
16-bit 3-signed-digit(SOCP-relax)	156	96

Table 15.11: Comparison of the number of 16-bit shift-and-add operations required to implement the coefficient multiplications for a direct form and a complementary FIR lattice implementation of a Gaussian filter with 16-bit 3-signed-digit coefficients.

Figure 15.22 compares the overall amplitude response of the filter for exact coefficients, direct form coefficients implemented with 16-bit 3-signed-digits, complementary FIR lattice coefficients implemented with 16-bit, 3-signed-digits having an average of 3-signed-digits per coefficient allocated with the algorithm of Lim *et al.* and lattice coefficients optimised with SOCP-relaxation. Figure 15.23 compares the amplitude responses in the “pass-band” (up to d_{Bas}). Figure 15.24 compares the group delay responses in the “pass-band” (up to d_{Bas}).

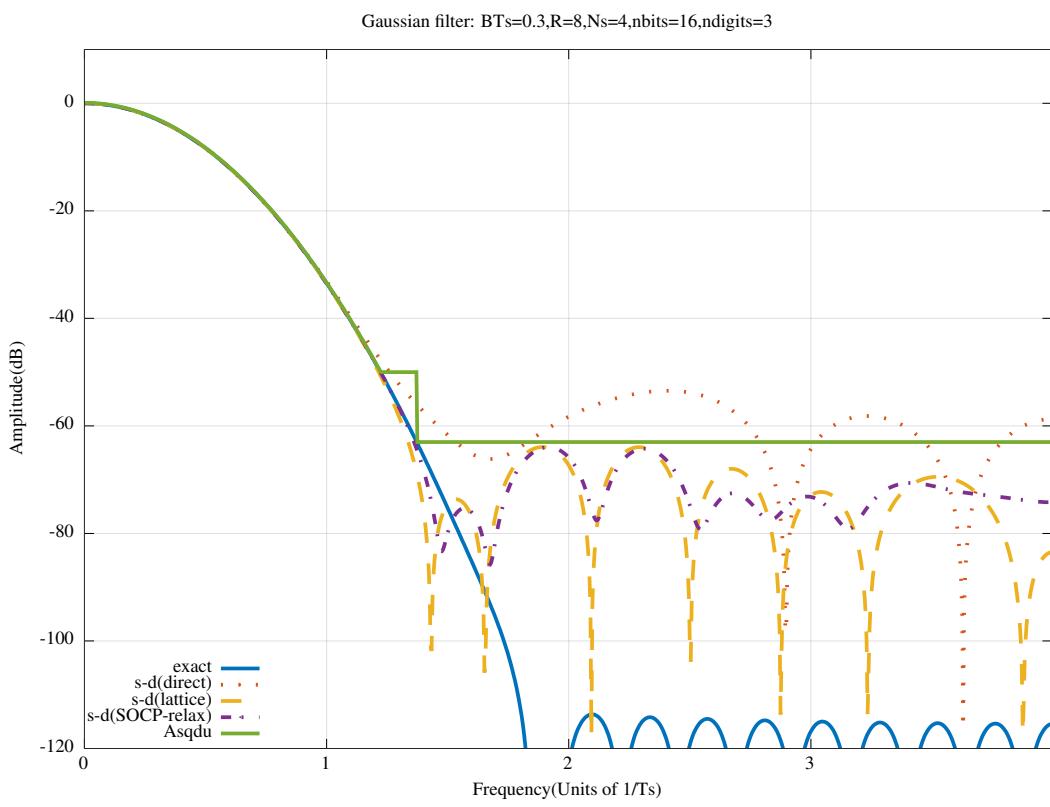

Figure 15.22: Comparison of the amplitude response of the FIR Gaussian filter for exact direct form coefficients, 16-bit 3-signed-digit direct form coefficients, 16-bit coefficients with an average of 3-signed-digits per coefficient and 16-bit coefficients with an average of 3-signed-digits per coefficient optimised by SOCP-relaxation.

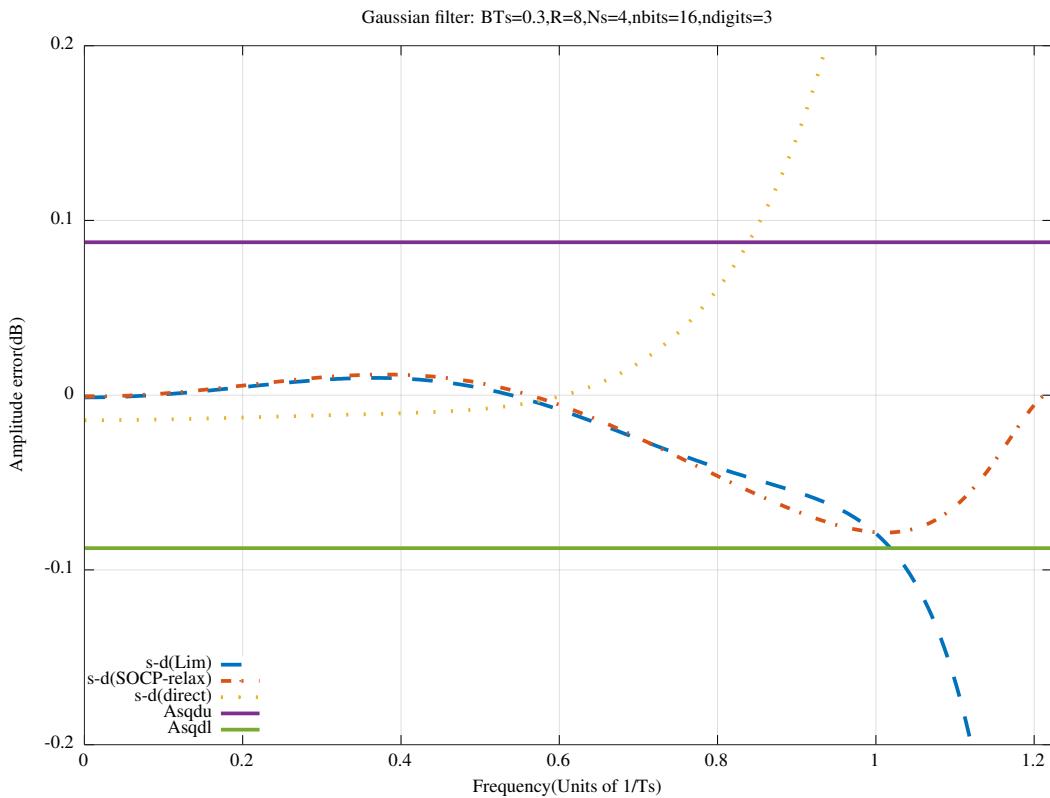

Figure 15.23: Comparison of the pass-band amplitude response of the FIR Gaussian filter for 16-bit coefficients with an average of 3-signed-digits per coefficient and 16-bit coefficients with an average of 3-signed-digits per coefficient optimised by SOCP-relaxation.

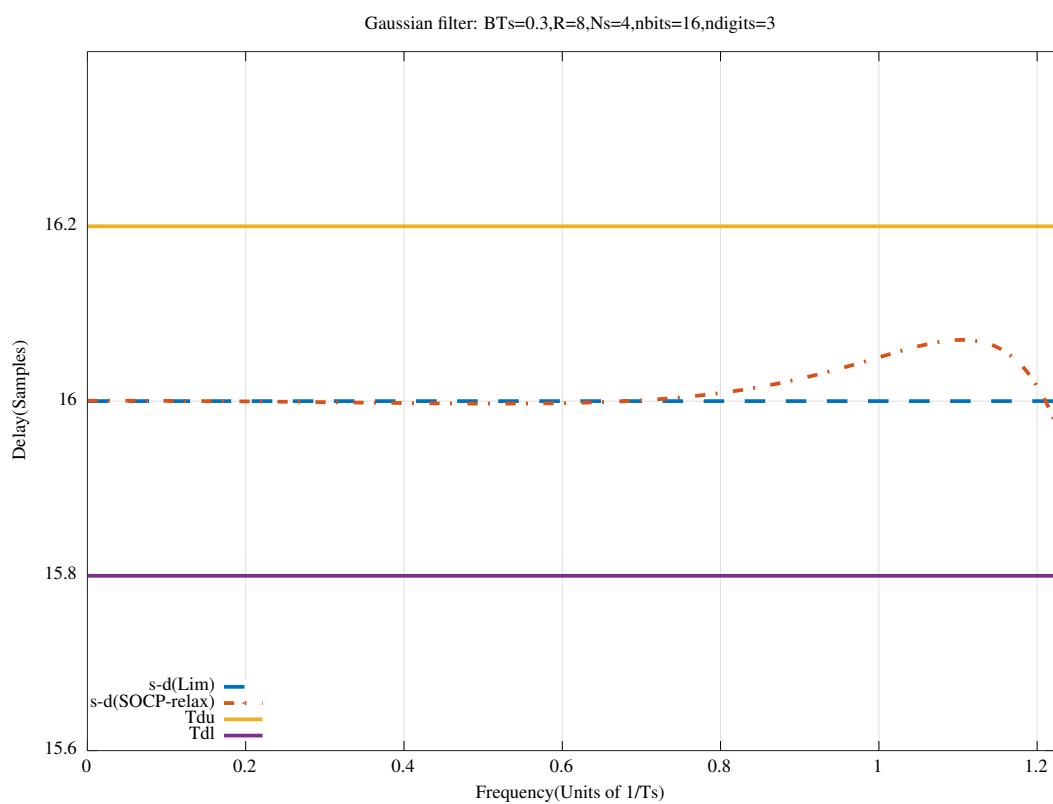

Figure 15.24: Comparison of the “pass-band” (up to d_{Bas}) group-delay response of the FIR Gaussian filter for 16-bit coefficients with an average of 3-signed-digits per coefficient and 16-bit coefficients with an average of 3-signed-digits per coefficient optimised by SOCP-relaxation.

Chapter 16

Semi-definite programming search for integer and signed-digit filter coefficients

This section follows the method introduced by *Lu* [167] and *Ito et al.* [137] to find the signed-digit coefficients of a direct-form FIR filter. The branch-and-bound algorithm of Section 14 and the successive coefficient relaxation methods of Section 15 perform SQP or SOCP optimisation at each coefficient optimisation relaxation step. Alternatively, the optimisation problem can be converted to an overall *integer programming* problem as follows: Given a set of exact coefficients, \mathbf{x} , and signed-power-of-two upper and lower bounds, \mathbf{u} and \mathbf{l} , corresponding to stable filter implementations such that $u_i \geq x_i \geq l_i$ for each of the N components of \mathbf{x} , define

$$\begin{aligned}\hat{\mathbf{x}} &= \frac{(\mathbf{u} + \mathbf{l})}{2} \\ \boldsymbol{\delta} &= \frac{(\mathbf{u} - \mathbf{l})}{2}\end{aligned}$$

Then $u_i = \hat{x}_i + y_i \delta_i$ if $y_i = 1$ and $l_i = \hat{x}_i + y_i \delta_i$ if $y_i = -1$. Define the filter coefficient vector as $\mathbf{x} = \hat{\mathbf{x}} + \mathbf{y} \circ \boldsymbol{\delta}$, where \circ represents the element-by-element product, and approximate the filter amplitude response by $A(\omega) \approx \hat{A}(\omega) + A_\delta(\omega)$ ^a. The weighted mean-squared-error of the filter amplitude response is approximately:

$$\mathcal{E} \approx \frac{1}{\pi} \int_0^\pi W(\omega) \left[\hat{A}(\omega) + A_\delta(\omega) - A_d(\omega) \right]^2 d\omega$$

The weighted mean-squared-error of the amplitude response, \mathcal{E} , of an IIR filter with signed-digit coefficients, $\hat{\mathbf{x}} + (\mathbf{y} \circ \boldsymbol{\delta})$, is approximately:

$$\mathcal{E} \approx \mathcal{E}(\hat{\mathbf{x}}) + \nabla_{\mathbf{x}} \mathcal{E}(\hat{\mathbf{x}})^T (\mathbf{y} \circ \boldsymbol{\delta}) + \frac{1}{2} (\mathbf{y} \circ \boldsymbol{\delta})^T \nabla_{\mathbf{x}}^2 \mathcal{E}(\hat{\mathbf{x}}) (\mathbf{y} \circ \boldsymbol{\delta}) \quad (16.1)$$

If $\mathbf{Y} = \mathbf{y} \mathbf{y}^T$ and $\boldsymbol{\Delta} = \boldsymbol{\delta} \boldsymbol{\delta}^T$, then mean-squared-error can be expressed in the form^b:

$$\mathcal{E} \approx \frac{1}{2} \text{trace}((\mathbf{Q} \circ \boldsymbol{\Delta}) \mathbf{Y}) + (\mathbf{q} \circ \boldsymbol{\delta}) \mathbf{y} + \text{const}$$

^aThis is an equality for an FIR filter transfer function.

^bThe elements of the product of two matrixes, \mathbf{R} and \mathbf{S} , of equal size, are:

$$[\mathbf{RS}]_{kl} = \sum_m R_{km} S_{ml}$$

The *trace* of a matrix is the sum of the diagonal elements:

$$\text{trace}(\mathbf{T}) = \sum_n T_{nn}$$

For a column vector, \mathbf{y} and a matrix, \mathbf{Q} :

$$\begin{aligned}\mathbf{y}^T \mathbf{Q} \mathbf{y} &= \sum_k \sum_l Q_{kl} y_k y_l \\ &= \sum_k \sum_l Q_{kl} Y_{kl} \\ &= \text{trace}(\mathbf{Q} \mathbf{Y})\end{aligned}$$

where $\mathbf{Y} = \mathbf{y} \mathbf{y}^T$ is symmetric.

The approximate minimum mean-squared-error is found by the integer programming optimisation:

$$\begin{aligned} & \text{minimise} \quad \text{trace}(\hat{\mathbf{Q}}\mathbf{Y}) + 2\hat{\mathbf{q}}\mathbf{y} \\ & \text{subject to} \quad y_i \in \{-1, 1\} \end{aligned}$$

The integer programming constraints are equivalent to:

$$Y_{ii} = 1, \quad \text{rank} \begin{bmatrix} \mathbf{Y} & \mathbf{y} \\ \mathbf{y}^T & 1 \end{bmatrix} = 1, \quad \begin{bmatrix} \mathbf{Y} & \mathbf{y} \\ \mathbf{y}^T & 1 \end{bmatrix} \succeq \mathbf{0}$$

where $\succeq 0$ means that the array is *positive semidefinite*. Lu [167, Section 2.3] suggests a relaxation of the integer programming problem by discarding the rank constraint. The resulting constraints are simplified by defining a symmetric matrix $\hat{\mathbf{Y}}$ with ones on the diagonal:

$$\begin{aligned} & \text{minimise} \quad \text{trace}(\hat{\mathbf{Q}}\hat{\mathbf{Y}}) + 2\hat{\mathbf{q}}\mathbf{y} \\ & \text{subject to} \quad \bar{\mathbf{Y}} = \begin{bmatrix} \hat{\mathbf{Y}} & \mathbf{y} \\ \mathbf{y}^T & 1 \end{bmatrix} \succeq \mathbf{0} \end{aligned}$$

Define a length $\frac{N(N+1)}{2}$ augmented variable, $\bar{\mathbf{y}}$, consisting of the N elements of \mathbf{y} and the $\frac{N(N-1)}{2}$ distinct off-diagonal elements of $\hat{\mathbf{Y}}$. The relaxed optimisation problem becomes:

$$\begin{aligned} & \text{minimise} \quad \mathbf{c}^T \bar{\mathbf{y}} \\ & \text{subject to} \quad \bar{\mathbf{Y}} \succeq \mathbf{0} \end{aligned}$$

Murumatsu and Suzuki [91, Section 3.3] and Ito et al. [137] add *triangle inequality* constraints:

$$\begin{aligned} y_i + y_j + \hat{Y}_{ij} &\geq -1 \\ y_i - y_j - \hat{Y}_{ij} &\geq -1 \\ -y_i - y_j + \hat{Y}_{ij} &\geq -1 \\ -y_i + y_j - \hat{Y}_{ij} &\geq -1 \end{aligned} \tag{16.2}$$

for $0 \leq i < j < N$.

Lu [166, Section V] shows how to solve this *semidefinite programming* optimisation problem with the *SeDuMi* [149] SOCP solver by representing it in the form:

$$\begin{aligned} & \text{minimise} \quad \mathbf{c}^T \bar{\mathbf{y}} \\ & \text{subject to} \quad \mathbf{A}\bar{\mathbf{y}} \geq \mathbf{b} \\ & \quad \bar{\mathbf{Y}} = \mathbf{F}_0 + \bar{y}_1 \mathbf{F}_1 + \dots + \bar{y}_P \mathbf{F}_P \succeq \mathbf{0} \end{aligned}$$

where $P = \frac{N(N+1)}{2}$, $\bar{\mathbf{y}} = [\bar{y}_1 \dots \bar{y}_P]^T$ and the \mathbf{F}_k are the symmetric matrixes that select the two off-diagonal elements of $\bar{\mathbf{Y}}$ corresponding to \bar{y}_k . If the SDP solution is \mathbf{y}^* and $\hat{\mathbf{Y}}^*$, then $\text{sign}(\mathbf{y}^*)$ is a reasonable solution to the original integer programming problem. Lu [167] points out that, given the singular-value decomposition

$$Z^* = \begin{bmatrix} \hat{\mathbf{Y}}^* & \mathbf{y}^* \\ \mathbf{y}^{*T} & 1 \end{bmatrix} = U\Sigma U^T$$

an alternative solution is $\text{sign}(u_{N+1,l} u_{1\dots N,l})$, where $u_{1\dots N,l}$ is the first column vector in U that corresponds to the largest singular value, σ_l . “The motivation ... is that a perfect solution \mathbf{Y}^* ... would imply that matrix Z^* has rank one, hence $\sigma_l u_{1\dots N+1,l} u_{1\dots N+1,l}^T$ is the best rank-one approximation of Z^* in the 2-norm sense.”

16.1 SDP optimisation of the signed-digit coefficients of a direct-form symmetric FIR filter

Following Appendix L.2, the components of the amplitude responses of a direct-form symmetric FIR filter with signed-digit coefficients are:

$$\hat{A}(\omega) = \hat{x}_M + 2 \sum_{n=0}^{M-1} \hat{x}_n \cos(M-n)\omega$$

$$A_\delta(\omega) = y_M \delta_M + 2 \sum_{n=0}^{M-1} y_n \delta_n \cos(M-n)\omega$$

The Octave script *sdp_relaxation_directFIRsymmetric_bandpass_10_nbites_test.m* performs SDP optimisation of the response of a direct-form symmetric band-pass FIR filter. The filter specification is:

```
nbits=10 % Coefficient bits
ndigits=3 % Nominal average coefficient signed-digits
tol=1e-06 % Tolerance on coef. update
ctol=1e-06 % Tolerance on constraints
npoints=1000 % Frequency points across the band
fapl=0.1 % Amplitude pass band lower edge
fapu=0.2 % Amplitude pass band upper edge
dBap=1.5 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
fasl=0.05 % Amplitude stop band(1) lower edge
fasu=0.25 % Amplitude stop band(1) upper edge
dBas=43 % Amplitude stop band(1) peak-to-peak ripple
Wasl=100 % Amplitude lower stop band weight
Wasu=100 % Amplitude upper stop band weight
```

The filter coefficients are truncated to 10 bits allocated with an average of 3 signed-digits by the heuristic of *Lim et al.* as shown in Section 11.1. The Octave function *directFIRsymmetric_sdp_mmsePW* implements SDP optimisation with the triangle inequalities of Equation 16.2. The resulting y values were all very close to -1 or 1 . Attempts at PCLS optimisation with *directFIRsymmetric_slb* failed.

The distinct direct-form symmetric FIR bandpass filter coefficients found by the SDP optimisation with triangle inequalities are:

```
hM1_sd_sdp = [ 0, -5, -10, -5, ...
    11, 20, 10, -2, ...
    5, 20, 0, -58, ...
   -91, -36, 75, 132 ]'/512;
```

Figure 16.1 compares the responses of the filter with exact, 10-bit signed-digit coefficients, 10-bit signed-digit coefficients allocated with the algorithm of *Lim et al.* and 10-bit signed-digit coefficients allocated with the algorithm of *Lim et al.* and SDP optimisation. Table 16.1 compares the cost and the number of 10 bit shift-and-add operations required to implement the 16 distinct coefficient multiplications found by the signed-digit allocation heuristic of *Lim et al.* with the SDP optimisation and triangle inequalities.

	Cost	Stop-band response	Signed-digits	Shift-and-adds
Exact	0.001901	-43.0		
10-bit 3-signed-digit	0.005824	-33.5	34	20
10-bit 3-signed-digit(Lim)	0.002063	-37.8	36	22
10-bit 3-signed-digit(SDP)	0.001874	-40.5	33	19

Table 16.1: Comparison of the cost, maximum stop-band response and number of 10-bit shift-and-add operations required to implement the coefficient multiplications for a direct-form symmetric FIR bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SDP optimisation with triangle inequalities.

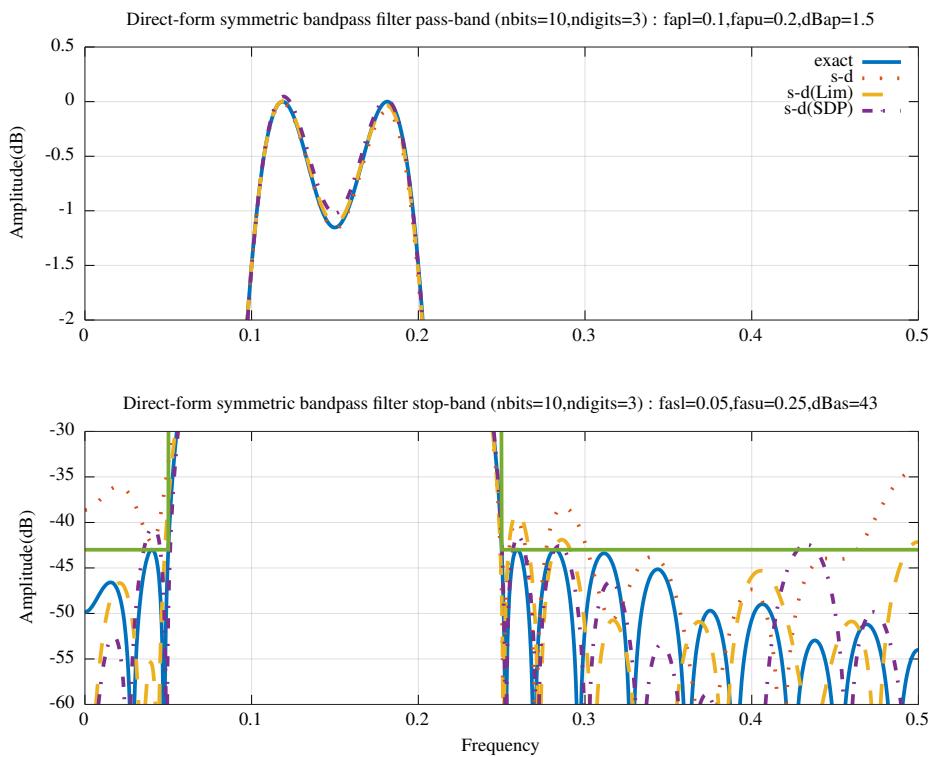

Figure 16.1: Comparison of the amplitude responses for a direct-form symmetric FIR bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SDP optimisation with triangle inequalities.

16.2 SDP optimisation of the signed-digit coefficients of an FIR Hilbert filter

The Octave script `sdp_relaxation_directFIRhilbert_12_nbits_test.m` performs SDP optimisation of the response of a direct-form Hilbert FIR filter. The filter specification is:

```
nbits=12 % Coefficient bits
ndigits=2 % Nominal average coefficient signed-digits
tol=1e-05 % Tolerance on coef. update
ctol=1e-05 % Tolerance on constraints
npoints=500 % Frequency points across the band
fapl=0.01 % Amplitude pass band lower edge
fapu=0.49 % Amplitude pass band upper edge
dBap=0.135 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
Was=0 % Amplitude stop band weight
```

The filter coefficients are truncated to 12 bits allocated with an average of 2 signed-digits by the heuristic of *Ito et al.* as shown in Section 11.2. The Octave function `directFIRhilbert_sdp_mmsePW` implements SDP optimisation with the triangle inequalities of Equation 16.2. The resulting y values were all very close to -1 or 1 .

The distinct direct-form Hilbert FIR filter coefficients found by signed-digit allocation with the heuristic of *Ito et al.* are:

```
hM1_sd_Ito = [ 1304, 432, 258, 183, ...
    140, 112, 96, 80, ...
    68, 60, 52, 48, ...
    40, 36, 32, 28, ...
    24, 24, 20, 20, ...
    16, 16, 12, 12, ...
    10, 9, 8, 8, ...
    6, 4, 4, 4, ...
    4, 4, 2, 2, ...
    2, 2, 1, 1 ]'/2048;
```

and by SDP optimisation with triangle inequalities are:

```
hM1_sd_sdp = [ 1304, 432, 258, 183, ...
    140, 112, 96, 80, ...
    68, 60, 52, 48, ...
    40, 36, 32, 30, ...
    24, 24, 20, 18, ...
    16, 16, 12, 12, ...
    10, 9, 8, 8, ...
    6, 4, 4, 4, ...
    2, 2, 2, 2, ...
    1, 1, 1, 1 ]'/2048;
```

The corresponding FIR filter is:

```
h=[-fliplr(kron(hM1_sd_sdp,[1;0]));0;kron(hM1_sd_sdp,[1;0])](2:end-1)
```

Figure 16.2 compares the responses of the filter with exact, 12-bit signed-digit coefficients, 12-bit signed-digit coefficients allocated with the algorithm of *Ito et al.* and 12-bit signed-digit coefficients allocated with the algorithm of *Ito et al.* and SDP optimisation. Table 16.2 compares the cost, maximum pass-band response error and the number of 12 bit shift-and-add operations required to implement the 40 distinct coefficient multiplications found by the signed-digit allocation heuristic of *Ito et al.* and performing SDP optimisation with triangle inequalities.

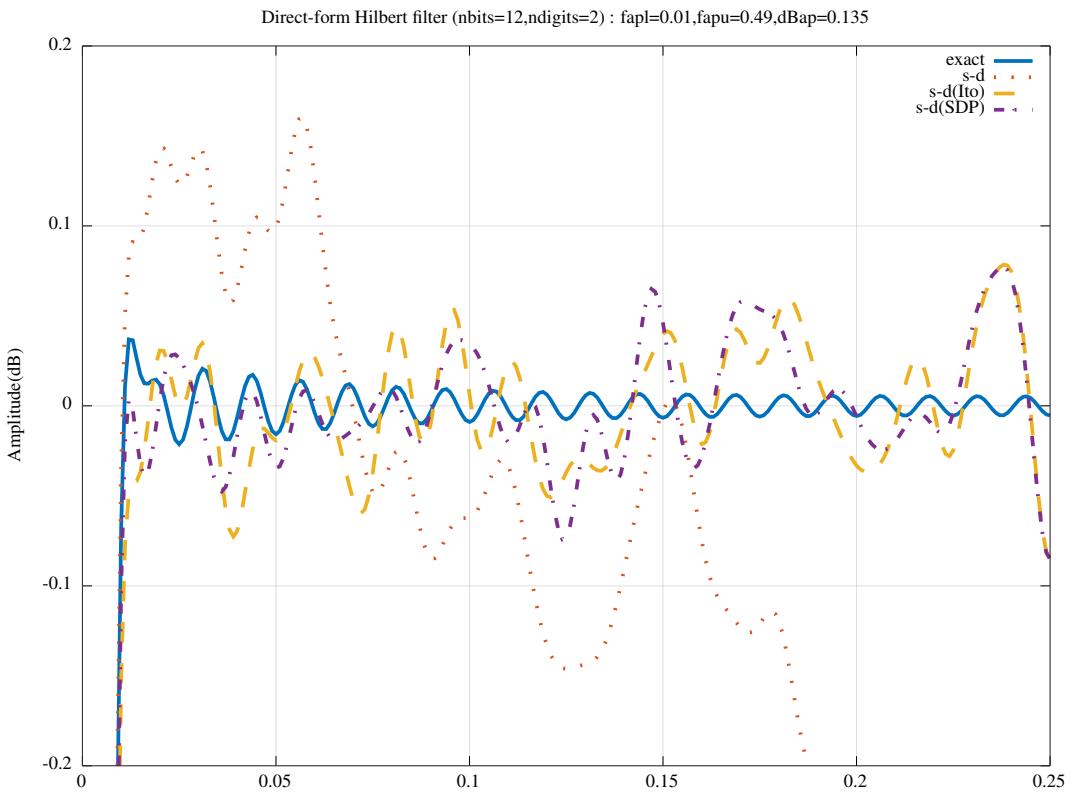

Figure 16.2: Comparison of the amplitude responses for a direct-form Hilbert FIR filter with 12-bit integer coefficients found by allocating an average of 2-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SDP optimisation with triangle inequalities.

	Cost	Pass-band response	Signed-digits	Shift-and-adds
Exact	4.693e-07	0.0675		
12-bit 2-signed-digit	0.0002078	0.417	71	31
12-bit 2-signed-digit(Ito)	7.63e-06	0.1519	71	31
12-bit 2-signed-digit(SDP)	6.44e-06	0.1007	71	31

Table 16.2: Comparison of the cost, maximum pass-band response error and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for a direct-form Hilbert FIR filter with 12-bit integer coefficients found by allocating an average of 2-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SDP optimisation with triangle inequalities.

16.3 SDP optimisation of the signed-digit coefficients of an FIR Hilbert band-pass filter

The Octave script `sdp_relaxation_directFIRhilbert_bandpass_12_nbites_test.m` performs SDP optimisation of the response of a direct-form Hilbert band-pass FIR filter. The initial filter is that shown in Appendix L.3.2. The filter specification is:

```
nbits=12 % Coefficient bits
ndigits=2 % Nominal average coefficient signed-digits
tol=1e-05 % Tolerance on coef. update
ctol=1e-05 % Tolerance on constraints
npoints=5000 % Frequency points across the band
M=8 % M distinct coefficients
fasl=0.1 % Amplitude stop band lower edge
fapl=0.16325 % Amplitude pass band lower edge
fapu=0.33675 % Amplitude pass band upper edge
fasu=0.4 % Amplitude stop band upper edge
Wap=2 % Amplitude pass band weight
dBap=0.1 % Amplitude pass band peak-to-peak ripple
Wat=0.001 % Amplitude transition band weight
Was=1 % Amplitude stop band weight
dBas=35 % Amplitude stop band peak ripple
```

The group-delay of the filter is $2M$ samples. The filter coefficients are truncated to 12 bits allocated with an average of 2 signed-digits by the heuristic of *Ito et al.* as shown in Section 11.2. The Octave function `directFIRhilbert_sdp_mmsePW` implements SDP optimisation with the triangle inequalities of Equation 16.2.

The distinct direct-form Hilbert band-pass FIR filter coefficients found by signed-digit allocation with the heuristic of *Ito et al.* are:

```
hM2_sd_Ito = [ 868, -327, -112, 128, ...
    32, -64, -8, 20 ]'/2048;
```

and by SDP optimisation with triangle inequalities are:

```
hM2_sd_sdp = [ 872, -326, -120, 128, ...
    32, -64, -8, 24 ]'/2048;
```

Figure 16.3 compares the responses of the filter with exact, 12-bit signed-digit coefficients, 12-bit signed-digit coefficients allocated with the algorithm of *Ito et al.* and 12-bit signed-digit coefficients allocated with the algorithm of *Ito et al.* and SDP optimisation. Figure 16.4 compares the pass-band responses. Table 16.3 compares the cost, maximum stop-band response error and the number of 12 bit shift-and-add operations required to implement the 8 distinct coefficient multiplications found by the signed-digit allocation heuristic of *Ito et al.* with the SDP relaxation optimisation and triangle inequalities.

	Cost	Stop-band response	Signed-digits	Shift-and-adds
Exact	0.0001338	-34.97		
12-bit 2-signed-digit	0.0006283	-28.15	16	8
12-bit 2-signed-digit(Ito)	0.0001635	-33.11	16	8
12-bit 2-signed-digit(SDP)	0.0001392	-34.89	16	8

Table 16.3: Comparison of the cost, maximum stop-band response error and number of 12-bit shift-and-add operations required to implement the coefficient multiplications for a direct-form Hilbert band-pass FIR filter with 12-bit integer coefficients found by allocating an average of 2-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SDP optimisation with triangle inequalities.

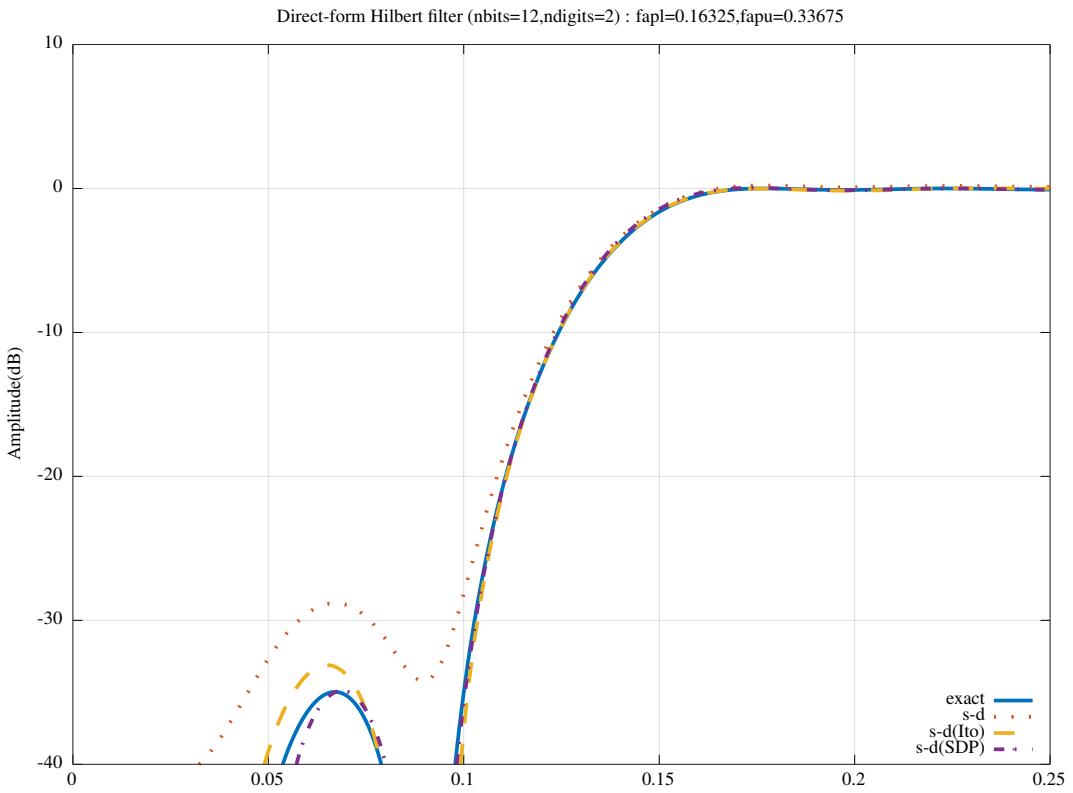

Figure 16.3: Comparison of the amplitude responses for a direct-form Hilbert band-pass FIR filter with 12-bit integer coefficients found by allocating an average of 2-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SDP optimisation with triangle inequalities.

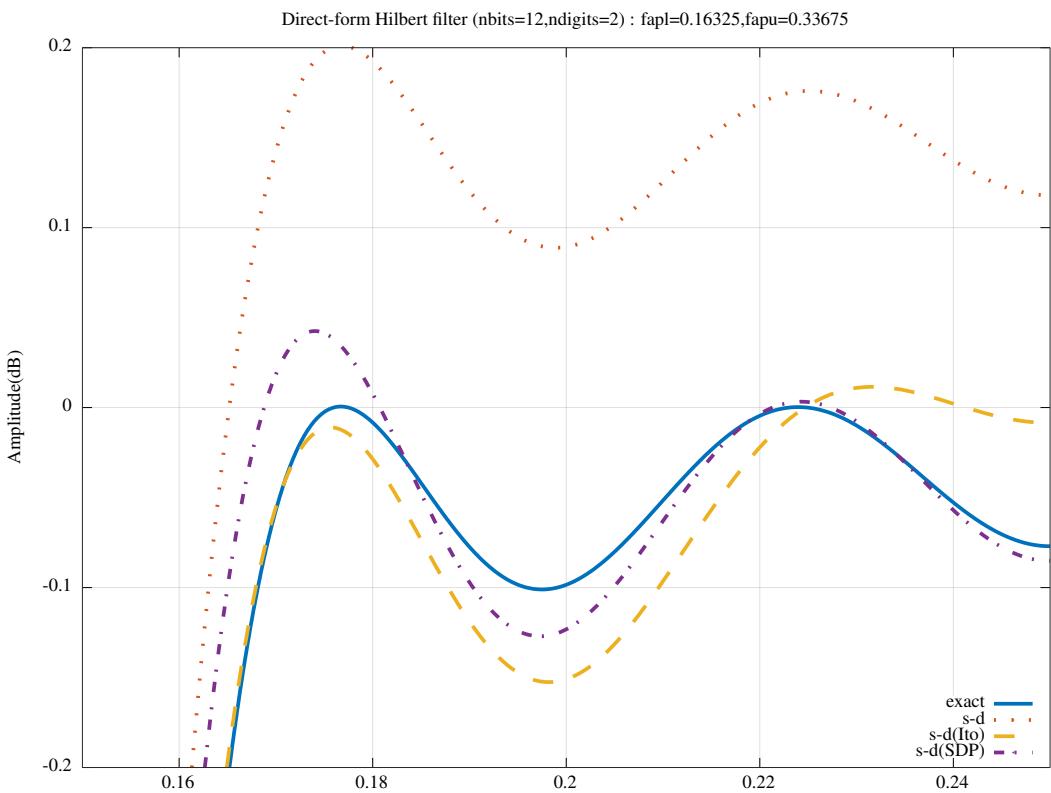

Figure 16.4: Comparison of the pass-band amplitude responses for a direct-form Hilbert band-pass FIR filter with 12-bit integer coefficients found by allocating an average of 2-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SDP optimisation with triangle inequalities.

16.4 SDP-relaxation search for the signed-digit coefficients of a lattice bandpass IIR filter

The Octave script *sdp_relaxation_schurOneMlattice_bandpass_10_nbis_test.m* performs successive SDP relaxations to optimise the response of the SQP optimised band-pass Schur one-multiplier lattice filter of Section 10.3.3. The filter specification is:

```

nbis=10 % Coefficient bits
ndigits=3 % Nominal average coefficient signed-digits
tol=2e-05 % Tolerance on coef. update
ctol=2e-05 % Tolerance on constraints
n=500 % Frequency points across the band
Nk=20 % Filter order
fapl=0.1 % Amplitude pass band lower edge
fapu=0.2 % Amplitude pass band upper edge
dBap=2 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
fasl=0.05 % Amplitude stop band lower edge
fasu=0.25 % Amplitude stop band upper edge
dBas=33 % Amplitude stop band peak-to-peak ripple
Wasl=500000 % Amplitude lower stop band weight
Wasu=1000000 % Amplitude upper stop band weight
ftpl=0.09 % Pass band delay lower edge
ftpu=0.21 % Pass band delay upper edge
tp=16 % Nominal pass band filter group delay
tpr=0.16 % Delay pass band peak-to-peak ripple
Wtp=5 % Delay pass band weight

```

The filter coefficients are truncated to 10 bits allocated with an average of 3 signed-digits by the heuristic of *Lim et al.* as shown in Section 11.1.

The script compares the filter designed by a single call to the Octave function *schurOneMlattice_sdp_mmse* with that designed by successively fixing the value of the remaining active coefficients to the SDP coefficient corresponding to that with the largest difference between the upper and lower signed-digit approximations as in Section 15.2. At each coefficient relaxation step the script finds the upper and lower signed-digit approximations to the current set of active coefficients and selects the coefficient with the largest difference in those approximations. Then the active coefficients are optimised with *schurOneMlattice_sdp_mmse*, the set of active coefficients is updated and the remaining active coefficients are optimised with the Octave function *schurOneMlattice_socp_mmse* and the *Selesnick-Lang-Burrus* constraint algorithm implemented in the Octave function *schurOneMlattice_slb*. The truncation of the last coefficient is, by necessity, not PCLS optimised so the final set of coefficients may not meet the PCLS specifications.

The filter coefficients found by a single “global” SDP optimisation are:

```

k0_sd_sdp = [      0,      338,      0,      256, ...
                 0,      177,      0,      208, ...
                 0,      156,      0,      129, ...
                 0,       76,      0,       53, ...
                 0,       18,      0,        8 ]'/512;

c0_sd_sdp = [     36,       -6,     -153,     -248, ...
                -82,       61,      202,      155, ...
                  9,      -43,      -42,       -6, ...
                 -5,      -18,      -14,        4, ...
                 14,        9,        1,        0, ...
                  2 ]'/512;

```

The filter coefficients found by the SDP-relaxation search are:

```

k0_sd_min = [      0,      340,      0,      251, ...
                 0,      177,      0,      208, ...
                 0,      152,      0,      125, ...
                 0,       76,      0,       51, ...
                 0,       18,      0,        7 ]'/512;

```

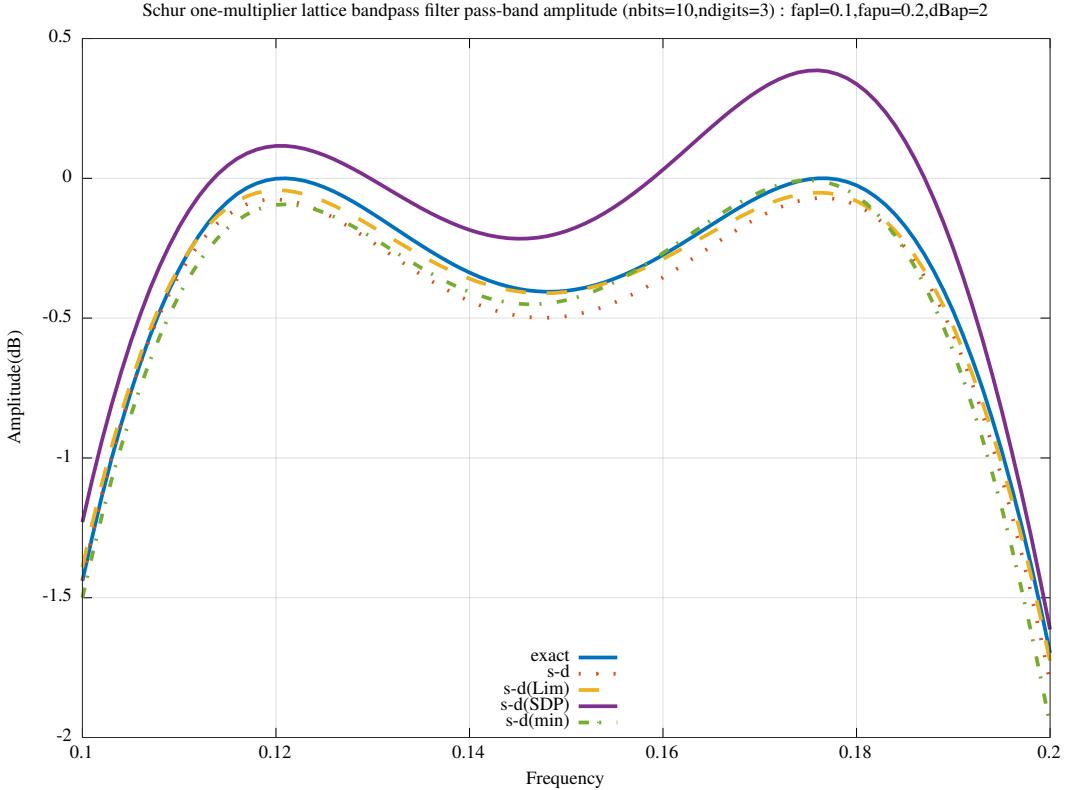

Figure 16.5: Comparison of the pass-band amplitude responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of Lim et al. and performing SDP-relaxation search

```
c0_sd_min = [      34,      -9,     -153,     -236, ...
    -76,      64,      197,      146, ...
      7,     -42,     -40,      -6, ...
     -5,     -17,     -12,      2, ...
    12,       8,       2,       0, ...
      2 ] '/512;
```

Figure 16.5 compares the pass-band responses of the filter with exact, 10-bit signed-digit coefficients allocated with the algorithm of Lim et al. and 10-bit signed-digit coefficients allocated with the algorithm of Lim et al. and SDP-relaxation search. Figure 16.6 shows the filter stop-band response and Figure 16.7 shows the filter pass-band group delay response. Table 16.4 compares the cost and the number of 10 bit shift-and-add operations required to implement the 20 coefficient multiplications found by the signed-digit allocation heuristic of Lim et al. with the SDP-relaxation search. A further 51 additions are required by the lattice filter structure. Figure 16.7 shows that the “global” unconstrained SDP optimisation gives a poor delay response. Application of the Selesnick-Lang-Burrus PCLS algorithm to the signed-digit SDP optimisation failed by entering a loop of constraints.

	Cost	Stop-band response	Signed-digits	Shift-and-adds
Exact	0.014720	-36.0		
10-bit 3-signed-digit	0.028230	-34.3	73	42
10-bit 3-signed-digit(Lim)	0.032866	-34.8	76	45
10-bit 3-signed-digit(SDP)	0.270464	-34.8	75	45
10-bit 3-signed-digit(min)	0.024289	-33.7	74	44

Table 16.4: Comparison of the cost and number of 10-bit shift-and-add operations required to implement the coefficient multiplications for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of Lim et al. and performing SDP-relaxation search

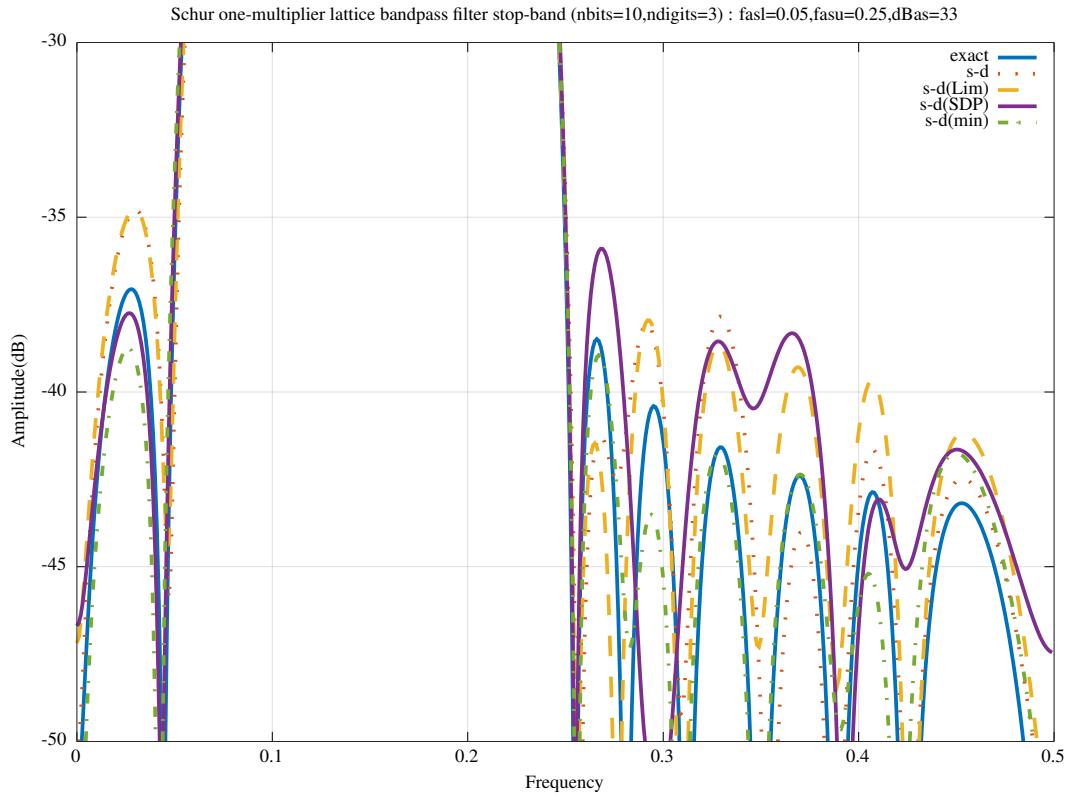

Figure 16.6: Comparison of the stop-band amplitude responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SDP-relaxation search

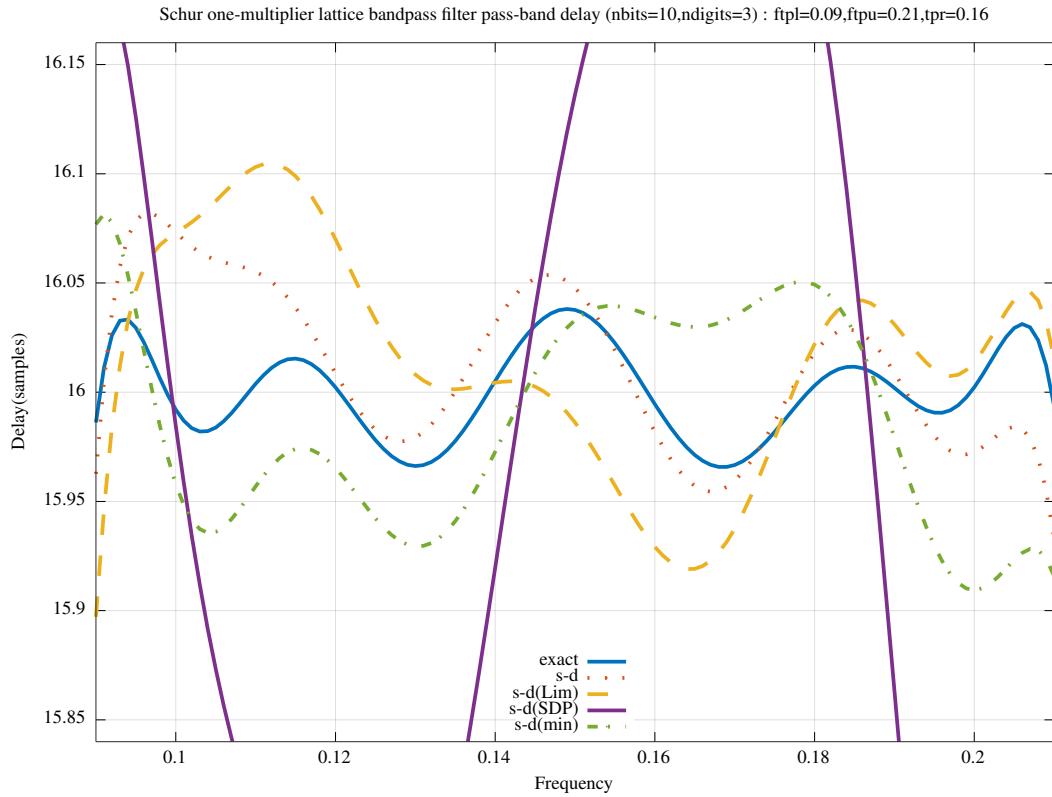

Figure 16.7: Comparison of the pass-band group delay responses for a Schur one-multiplier lattice bandpass filter with 10-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SDP-relaxation search

16.5 SDP-relaxation search for the signed-digit coefficients of a parallel allpass lattice elliptic low-pass IIR filter

The Octave script *sdp_relaxation_schurOneMPAlattice_elliptic_lowpass_16_nbis_test.m* performs successive SDP relaxations to optimise the response of an elliptic low-pass filter implemented with 16-bit coefficients. The filter specification is:

```
nbits=16 % Coefficient bits
ndigits=4 % Nominal average coefficient signed-digits
tol=1e-05 % Tolerance on coef. update
ctol=1e-08 % Tolerance on constraints
n=1000 % Frequency points across the band
difference=0 % Use difference of all-pass filters
rho=0.992188 % Constraint on allpass coefficients
m1=5 % All-pass filter 1 order
m2=4 % All-pass filter 2 order
fap=0.15 % Amplitude pass band edge
dBap=0.06 % Amplitude pass band peak-to-peak ripple
Wape=0 % Extra amplitude pass band weight
Wap=1 % Amplitude pass band weight
fas=0.171 % Amplitude stop band edge
dBas=76 % Amplitude stop band peak-to-peak ripple
Was=10000000 % Amplitude stop band weight
Wase=0 % Extra amplitude stop band weight
```

The filter specification is similar to that for the filter designed with branch-and-bound search shown in Section 14.6. The initial parallel all-pass filters are those for the filter designed by the Octave function *ellip(11,0.02,84,2*0.15)*. The filter coefficients are truncated to 16-bit coefficients with an average of 4 signed-digits allocated by the heuristic of *Ito et al.*, as shown in Section 11.2. The following numbers of signed-digits are allocated to the lattice coefficients:

```
A1k0_allocsd_digits = [ 4, 3, 5, 5, ...
4, 4 ]';
A2k0_allocsd_digits = [ 3, 3, 5, 5, ...
3 ]';
```

The script compares the filter designed by a single call to the Octave function *schurOneMPAlattice_sdp_mmse* with that designed by successively fixing the value of the remaining active coefficients to the SDP coefficient corresponding to that with the largest difference between the upper and lower signed-digit approximations as in Section 15.2. At each coefficient relaxation step the script finds the upper and lower signed-digit approximations to the current set of active coefficients and selects the coefficient with the largest difference in those approximations. Then the active coefficients are optimised with *schurOneMPAlattice_sdp_mmse*, the set of active coefficients is updated and the remaining active coefficients are optimised with the Octave function *schurOneMPAlattice_socp_mmse* and the Selesnick-Lang-Burrus constraint algorithm implemented in the Octave function *schurOneMPAlattice_slb*. The truncation of the last coefficient is, by necessity, not PCLS optimised so the final set of coefficients may not meet the PCLS specifications.

The filter coefficients found by the SDP-relaxation search are:

```
A1k0_sd_min = [ -19584, 32384, -25728, 28352, ...
-23616, 11808 ]'/32768;
A2k0_sd_min = [ -22560, 30680, -26880, 23936, ...
-11760 ]'/32768;
```

Figures 16.8 and 16.9 compare the pass-band and stop-band responses of the filter with exact, 16-bit coefficients with an average of 4 signed-digits allocated with the algorithm of *Ito et al.*, signed-digit coefficients found with “global” SDP approximation and those found by SDP-relaxation search. Table 16.5 compares the cost and the number of 16 bit shift-and-add operations required to implement the 11 coefficient multiplications.

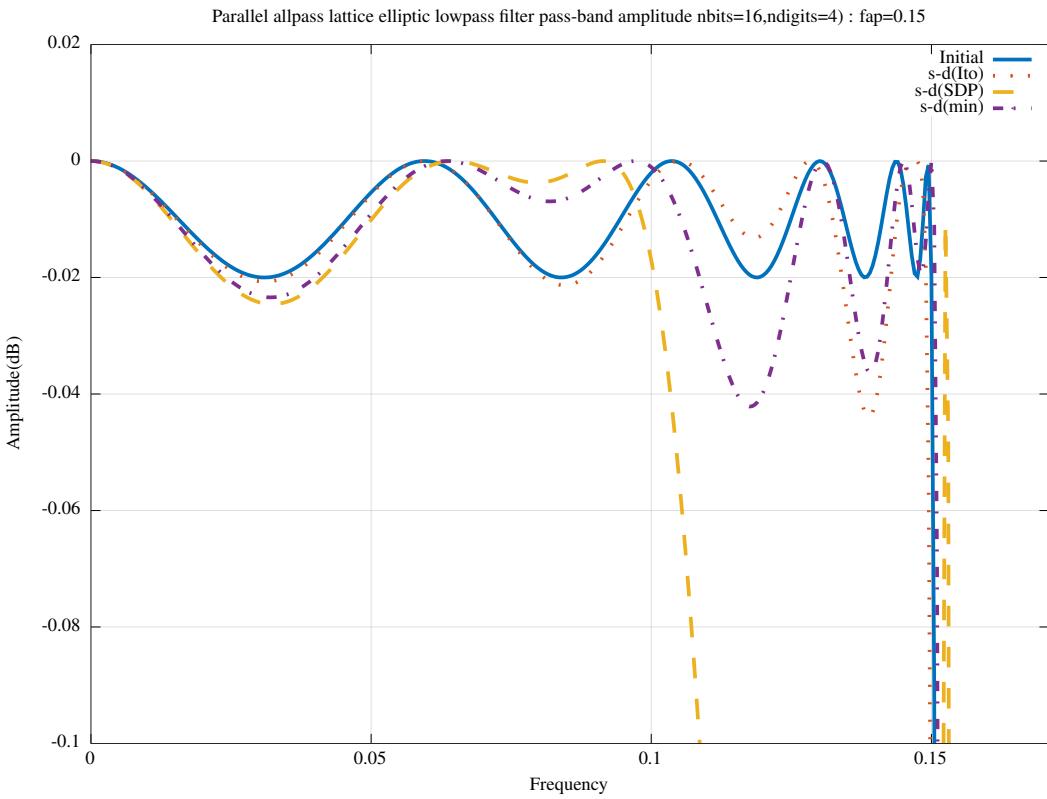

Figure 16.8: Comparison of the pass-band amplitude responses for a parallel all-pass Schur one-multiplier lattice elliptic low-pass filter with 16-bit integer coefficients found by allocating an average of 4-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SDP relaxation search

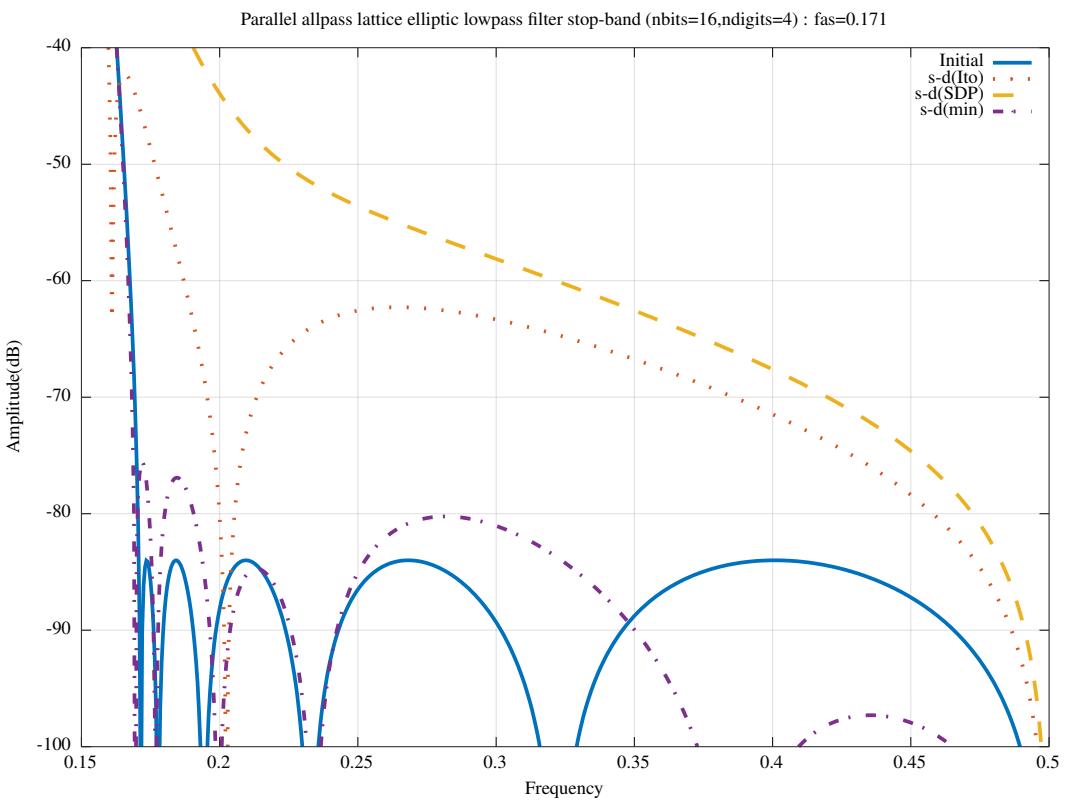

Figure 16.9: Comparison of the stop-band amplitude responses for a parallel all-pass Schur one-multiplier lattice elliptic low-pass filter with 16-bit integer coefficients found by allocating an average of 4-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SDP relaxation search

	Cost	Stop-band response	Signed-digits	Shift-and-adds
Initial	7.52e-06	-84.0		
16-bit 4-signed-digit(Ito)	1.76e-04	-45.2	44	33
16-bit 4-signed-digit(SDP)	6.00e-01	-27.5	44	33
16-bit 4-signed-digit(min)	1.40e-05	-75.6	43	32

Table 16.5: Comparison of the cost, stop-band attenuation and number of 16-bit shift-and-add operations required to implement the coefficient multiplications for a parallel all-pass Schur one-multiplier lattice elliptic-lowpass filter with 16-bit integer coefficients found by allocating an average of 4-signed-digits to each coefficient using the heuristic of *Ito et al.* and performing SDP relaxation search

16.6 SDP-relaxation search for the signed-digit coefficients of a parallel allpass lattice bandpass Hilbert IIR filter

The Octave script *sdp_relaxation_schurOneMPAlattice_bandpass_hilbert_13_nbites_test.m* performs successive SDP relaxations to optimise the response of the band-pass Hilbert filter designed by the script *parallel_allpass_socp_slb_bandpass_hilbert_test.m* described in Section 10.2.3 implemented with 13 bit coefficients each having an average of 3 signed-digits allocated by the heuristic of Lim *et al.* as shown in Section 11.1. The filter specification is:

```

nbites=13 % Coefficient bits
ndigits=3 % Nominal average coefficient signed-digits
tol=0.0001 % Tolerance on coef. update
ctol=1e-06 % Tolerance on constraints
n=1000 % Frequency points across the band
ma=10 % All-pass filter a order
mb=10 % All-pass filter b order
fapl=0.12 % Amplitude pass band lower edge
fapu=0.18 % Amplitude pass band upper edge
dBap=0.1 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
fasl=0.05 % Amplitude stop band lower edge
fasu=0.25 % Amplitude stop band upper edge
dBas=35 % Amplitude stop band peak-to-peak ripple
Wasl=2000 % Amplitude lower stop band weight
Wasu=2000 % Amplitude upper stop band weight
ftpl=0.12 % Pass band delay lower edge
ftpup=0.18 % Pass band delay upper edge
td=16 % Nominal pass band filter group delay
tdr=0.1 % Delay pass band peak-to-peak ripple
Wtp=2 % Delay pass band weight
fppl=0.12 % Pass band phase response lower edge
fppu=0.18 % Pass band phase response upper edge
pd=3.5 % Pass band initial phase response (rad./pi)
pdr=0.03 % Pass band phase response ripple(rad./pi)
Wpp=500 % Pass band phase response weight

```

The script compares the filter designed by a single call to the Octave function *schurOneMPAlattice_sdp_mmse* with that designed by successively fixing the value of the remaining active coefficients to the SDP coefficient corresponding to that with the largest difference between the upper and lower signed-digit approximations as in Section 15.2. At each coefficient relaxation step the script finds the upper and lower signed-digit approximations to the current set of active coefficients and selects the coefficient with the largest difference in those approximations. Then the active coefficients are optimised with *schurOneMPAlattice_sdp_mmse*, the set of active coefficients is updated and the remaining active coefficients are optimised with the Octave function *schurOneMPAlattice_socp_mmse* and the Selesnick-Lang-Burrus constraint algorithm implemented in the Octave function *schurOneMPAlattice_slb*. The truncation of the last coefficient is, by necessity, not PCLS optimised so the final set of coefficients may not meet the PCLS specifications.

The filter coefficients found by a single “global” SDP optimisation are:

```
A1k0_sd_sdp = [ -1732,      2564,      1952,     -2177, ...
                 2816,     -1152,     -256,       1568, ...
                -960,       384 ]'/4096;
```

```
A2k0_sd_sdp = [ -3114,      3004,      1880,     -2344, ...
                 2928,     -1044,     -240,       1536, ...
                -968,       448 ]'/4096;
```

The filter coefficients found by the SDP-relaxation search are:

```
A1k0_sd_min = [ -1793,      2528,      1952,     -2172, ...
                  2816,     -1152,     -256,       1568, ...
                 -960,       448 ]'/4096;
```

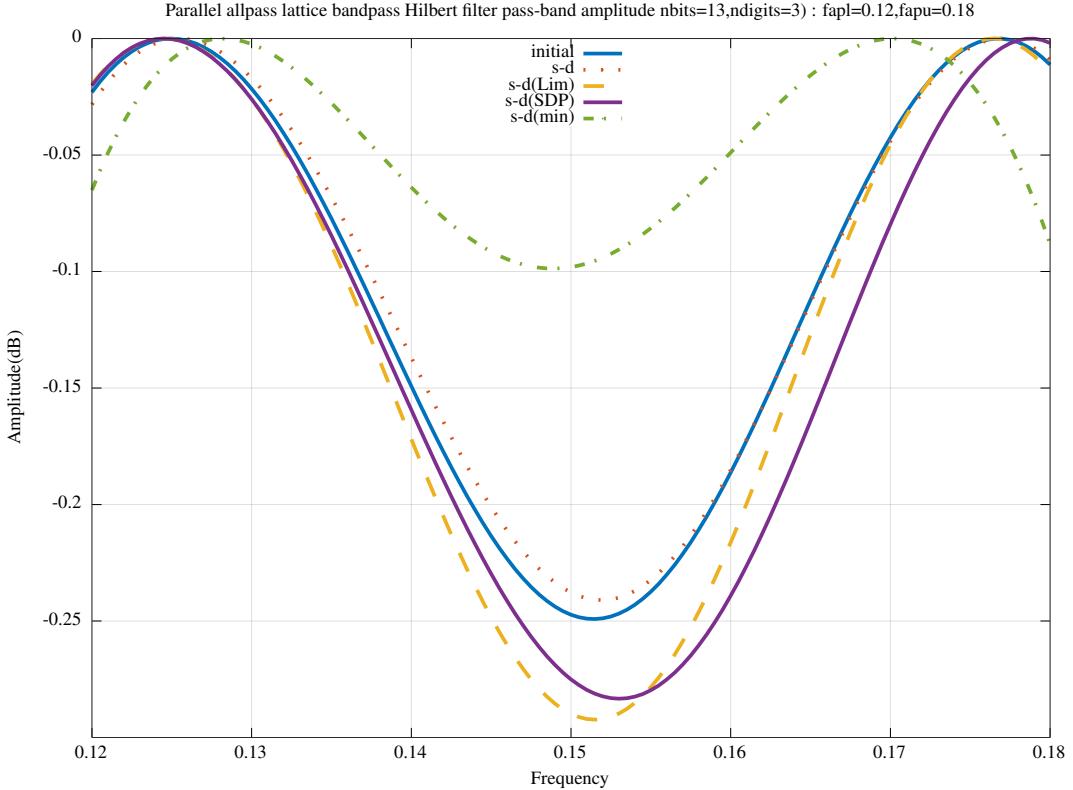

Figure 16.10: Comparison of the pass-band amplitude responses for a parallel all-pass Schur one-multiplier lattice bandpass Hilbert filter with 13-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SDP-relaxation search

```
A2k0_sd_min = [ -3110,      3016,      1880,      -2301, ...
                 2912,     -993,     -192,      1536, ...
                -928,      448 ] '/4096;
```

Figures 16.10, Figure 16.11 and Figure 16.12 compare the pass-band responses of the filter with exact, 13-bit signed-digit coefficients allocated with the algorithm of *Lim et al.* and 13-bit signed-digit coefficients allocated with the algorithm of *Lim et al.* and SDP-relaxation search. Likewise, Figure 16.13 shows the filter stop-band response. Table 16.6 compares the cost and the number of 13 bit shift-and-add operations required to implement the 20 coefficient multiplications found by the signed-digit allocation heuristic of *Lim et al.* with the SDP-relaxation search.

	Cost	Stop-band response	Signed-digits	Shift-and-adds
Exact	0.001399	-35.2		
13-bit 3-signed-digit	0.246859	-30.8	60	40
13-bit 3-signed-digit(Lim)	0.087099	-34.5	59	39
13-bit 3-signed-digit(SDP)	0.413571	-28.2	59	39
13-bit 3-signed-digit(min)	0.001315	-35.0	58	38

Table 16.6: Comparison of the cost and number of 13-bit shift-and-add operations required to implement the coefficient multiplications for a parallel all-pass Schur one-multiplier lattice bandpass Hilbert filter with 13-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SDP-relaxation search

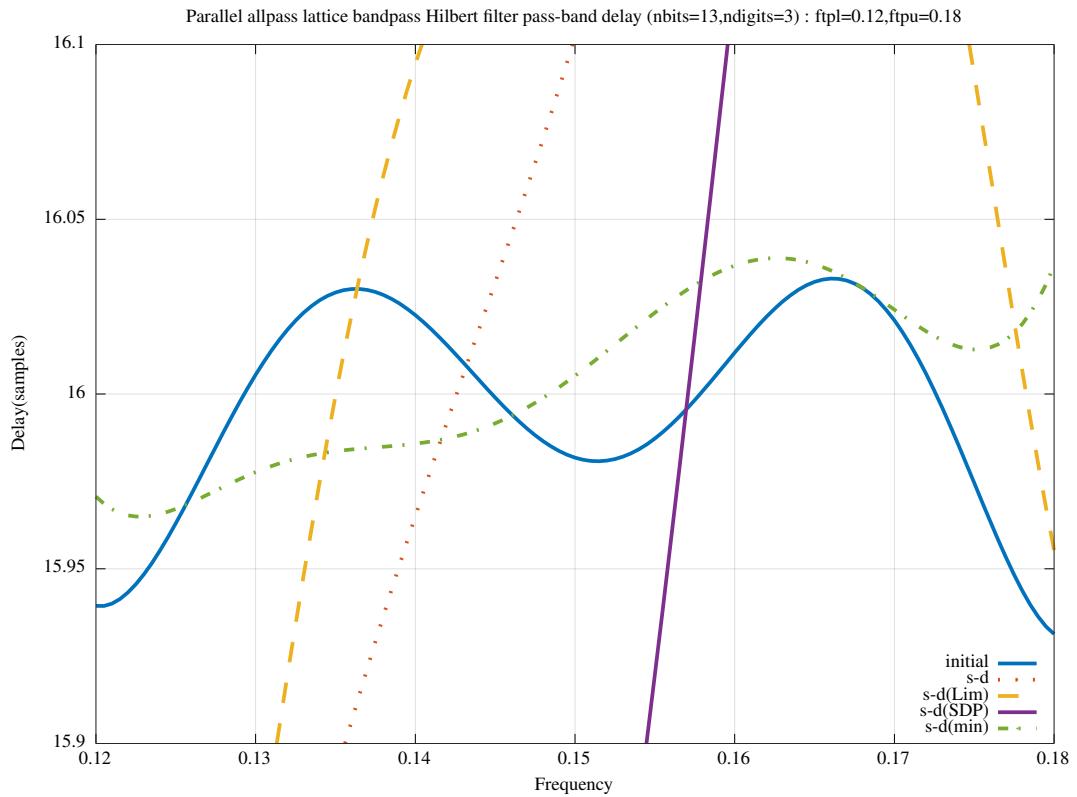

Figure 16.11: Comparison of the pass-band group delay responses for a parallel all-pass Schur one-multiplier lattice bandpass Hilbert filter with 13-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SDP-relaxation search

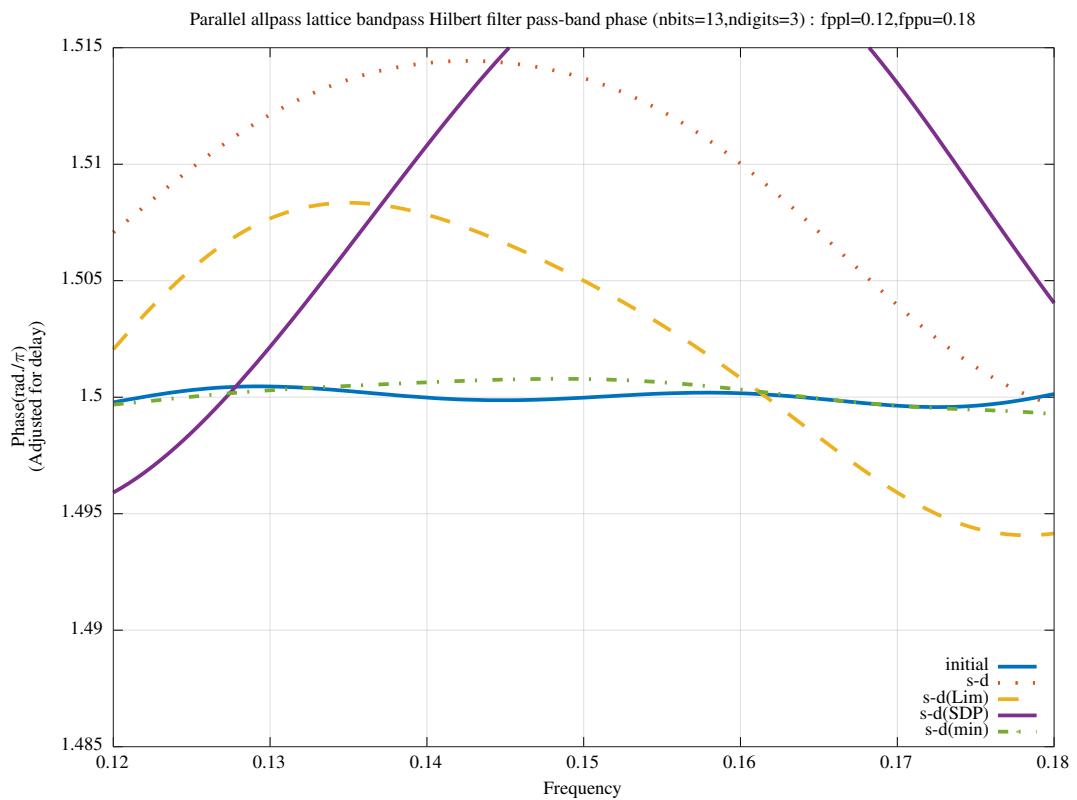

Figure 16.12: Comparison of the pass-band phase responses for a parallel all-pass Schur one-multiplier lattice bandpass Hilbert filter with 13-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SDP-relaxation search

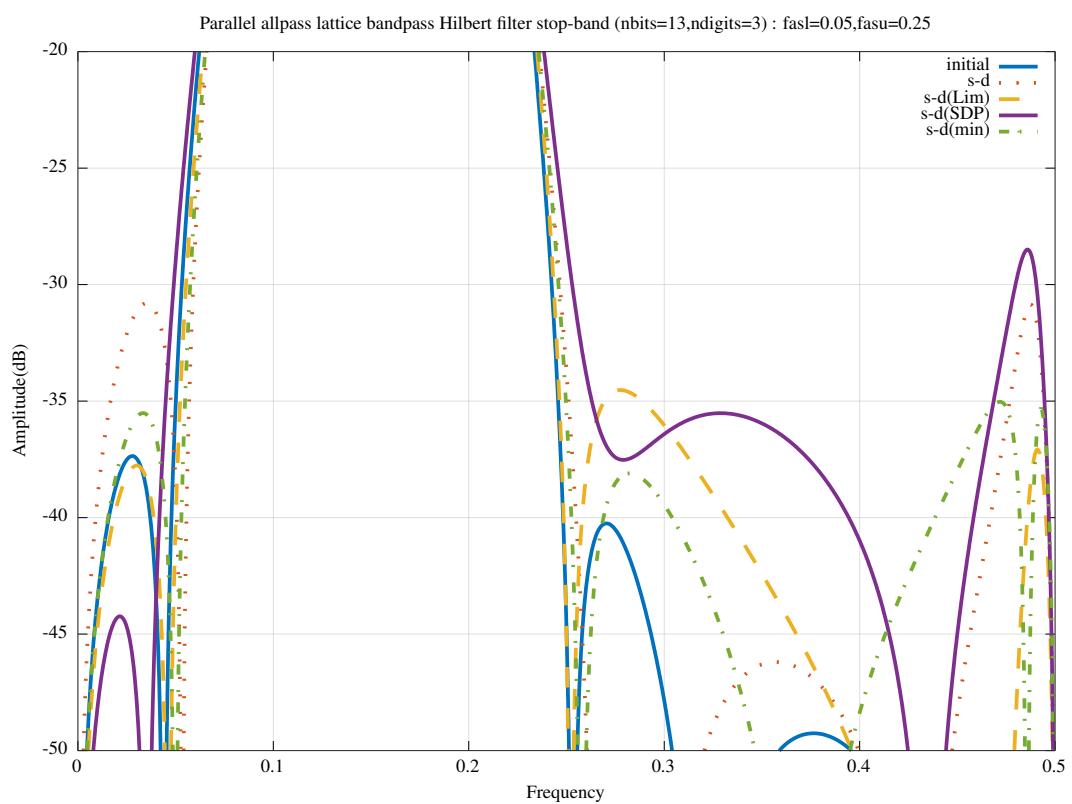

Figure 16.13: Comparison of the stop-band amplitude responses for a parallel all-pass Schur one-multiplier lattice bandpass Hilbert filter with 13-bit integer coefficients found by allocating an average of 3-signed-digits to each coefficient using the heuristic of *Lim et al.* and performing SDP-relaxation search

Chapter 17

Comparison of filter coefficient search methods for a 5th order elliptic filter with 6-bit integer and 2-signed-digit coefficients

The signed-digit allocation algorithms shown in Chapter 11 performed poorly when the coefficient word-length is less than 10. This chapter compares the results of “brute force” search for the 6-bit integer coefficients of a 5th order elliptic filter. The filter responses are compared to an ideal, “brick-wall”, amplitude response:

$$A(f) = \begin{cases} 1 & f \leq 0.125 \\ 0 & f > 0.150 \end{cases}$$

The response errors are weighted as follows:

$$W_a(f) = \begin{cases} 1 & f \leq 0.125 \\ 0.1 & 0.125 < f < 0.150 \\ 10 & f \geq 0.150 \end{cases}$$

The prototype filter is a 5-th order elliptic filter with pass-band edge at $f_{pass} = 0.125$, 1dB pass-band ripple and 40dB stop-band ripple:

```
% Specify elliptic low pass filter
norder=5; dBpass=1; dBstop=40; fpass=0.125;
[n0, d0]=ellip(norder, dBpass, dBstop, 2*fpass);
```

The prototype filter is implemented as a normalised-scaled lattice filter, parallel allpass normalised-scaled lattice filters, a one-multiplier lattice filter, parallel all-pass one-multiplier lattice filters and a cascade of two 2nd order minimum noise state variable sections followed by a first order section. The stability of each filter is maintained by checking the pole locations of the transfer function denominator polynomial in the corresponding cost function. For each optimisation algorithm and filter, I compare the cost function of the exact filter response to the response for each filter with the coefficients truncated as 6 bit rounded and 6 bit 2 signed-digits. I anticipate that the average number of signed digits used by the signed-digit coefficients will be less than 2. The 6 bit rounded coefficients can be represented exactly by 3 or fewer signed digits. Individual cases may be improved by “tweaking” the optimisation parameters.

17.1 Searching with the bit-flipping algorithm

The Octave script *bitflip_schurNSlattice_lowpass_test.m* implements the prototype elliptic filter as a normalised-scaled lattice and optimises the truncated coefficients with the bit-flipping algorithm using $nbits = 6$, $bitstart = 4$ and $msize = 3$. Figures 17.1 and 17.2 show the overall and passband responses of the prototype elliptic filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm. The cost function used with the signed-digit coefficients does not enforce the normalised-scaled orthogonal symmetry of $s_{00} = s_{22}$ and $s_{02} = -s_{20}$.

The Octave script *bitflip_schurOneMlattice_lowpass_test.m* implements the prototype elliptic filter as a one-multiplier lattice and optimises the truncated coefficients with the bit-flipping algorithm using $nbits = 6$, $bitstart = 4$ and $msize = 3$. Figures 17.3 and 17.4 show the overall and passband responses of the filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm. The one-multiplier lattice state scaling coefficients are not truncated.

Appendix K.2 shows how odd-order “classical” digital filter transfer functions can be implemented as the sum of two parallel all-pass filters. The Octave script *bitflip_schurNSPA_lattice_lowpass_test.m* implements the 5th order elliptic filter as the sum of two normalised-scaled all-pass lattice filters and optimises the truncated coefficients with the bit-flipping algorithm using $nbits = 6$, $bitstart = 4$ and $msize = 3$. Figures 17.5 and 17.6 show the overall and passband responses of the parallel all-pass filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm, 6 bit 2 signed-digit coefficients and 2 signed-digit coefficients optimised with the bit-flipping algorithm. The cost function used with the signed-digit coefficients does not enforce the normalised-scaled orthogonal symmetry of $s_{00} = s_{22}$ and $s_{02} = -s_{20}$.

The Octave script *bitflip_schurOneMPA_lattice_lowpass_test.m* implements the 5th order elliptic filter as the sum of two one-multiplier all-pass lattice filters and optimises the truncated coefficients with the bit-flipping algorithm using $nbits = 6$, $bitstart = 4$ and $msize = 3$. Figures 17.7 and 17.8 show the overall and passband responses of the parallel all-pass filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm and 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm. The one-multiplier lattice state scaling coefficients are not truncated. The structural boundedness of the parallel all-pass one-multiplier lattice filter is evident.

Finally, the Octave script *bitflip_svccasc_lowpass_test.m* implements the 5th order elliptic filter as a pair of 2nd order minimum-noise state variable sections followed by a 1st order state variable section. (See Section 4). The script optimises the truncated coefficients with the bit-flipping algorithm using $nbits = 6$, $bitstart = 4$ and $msize = 3$. Figures 17.9 and 17.10 show the overall and passband responses of the filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm. Note that the 2nd order state variable cascade filter obtained by simply converting the exact coefficients to 6 bit 2 signed-digit coefficients is unstable.

Table 17.1 compares the cost result for each test of the bit-flipping algorithm.

Cost	Normalised-scaled lattice	One-multiplier lattice	Normalised-scaled PA lattice	One-multiplier PA lattice	2nd Order cascade
Exact	1.0008	1.0008	1.0008	1.0008	1.0008
Rounded	1.5432	1.5299	1.2459	1.1097	1.2362
Rounded with bit-flipping	1.1289	1.5299	0.9861	1.1097	0.9929
Signed-digit	2.3373	2.7157	3.6059	3.9013	∞
Signed-digit with bit-flipping	0.8744	2.1571	1.3824	3.1746	1.1334

Table 17.1: Summary of the cost results for the example 5th order elliptic low-pass filter synthesised as a normalised-scaled or one-multiplier lattice filter or as a cascade of 2nd order state variable sections with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm

The normalised-scaled 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm are:

```
s10_bfsd = [ 0.968750, 0.875000, 0.468750, 0.187500, 0.031250 ]';
s11_bfsd = [ 0.000000, 0.875000, 0.937500, 1.000000, 0.468750 ]';
s20_bfsd = [ -0.750000, 0.937500, -0.875000, 0.750000, -0.468750 ]';
s00_bfsd = [ 0.625000, 0.312500, 0.468750, 0.562500, 0.875000 ]';
s02_bfsd = [ 0.750000, -0.968750, 0.875000, -0.750000, 0.437500 ]';
s22_bfsd = [ 0.625000, 0.218750, 0.468750, 0.500000, 0.875000 ]';
```

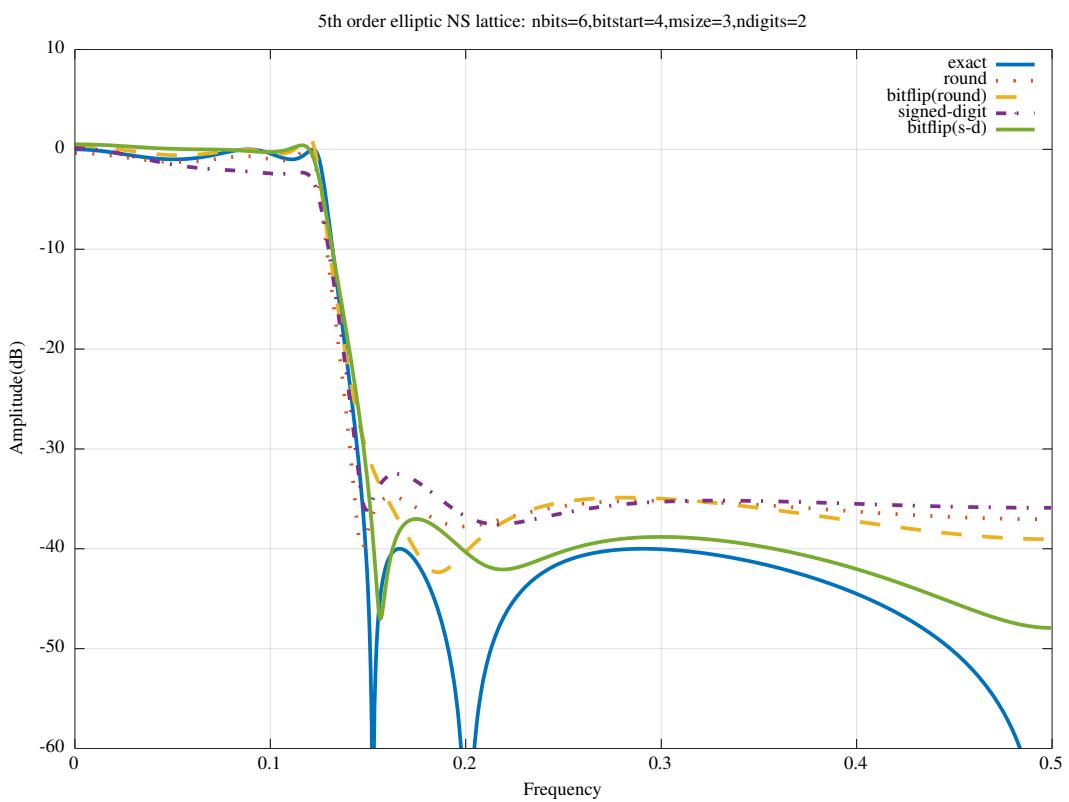

Figure 17.1: Amplitude response of the 5th order elliptic low-pass filter synthesised as a normalised-scaled lattice filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm, 6 bit 2 signed-digit coefficients, and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm

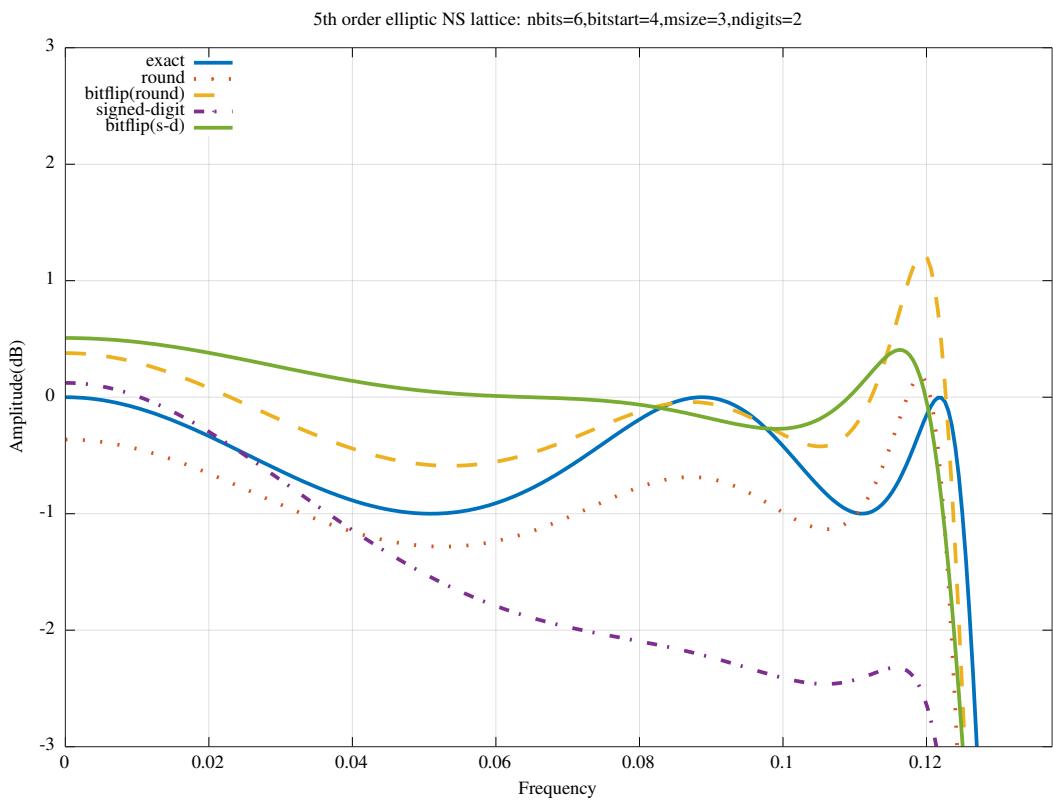

Figure 17.2: Pass-band amplitude response of the 5th order elliptic low-pass filter synthesised as a normalised-scaled lattice filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm, 6 bit 2 signed-digit coefficients, and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm

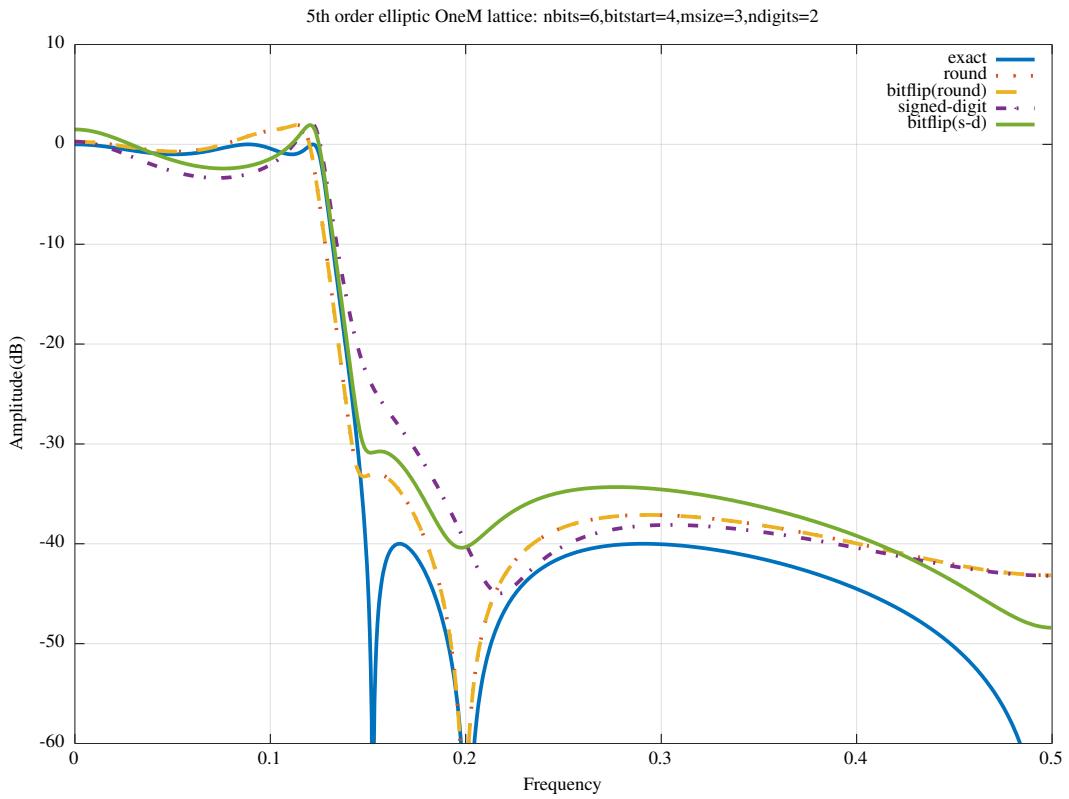

Figure 17.3: Amplitude response of the 5th order elliptic low-pass filter synthesised as a one multiplier lattice filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm, 6 bit 2 signed-digit coefficients, and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm

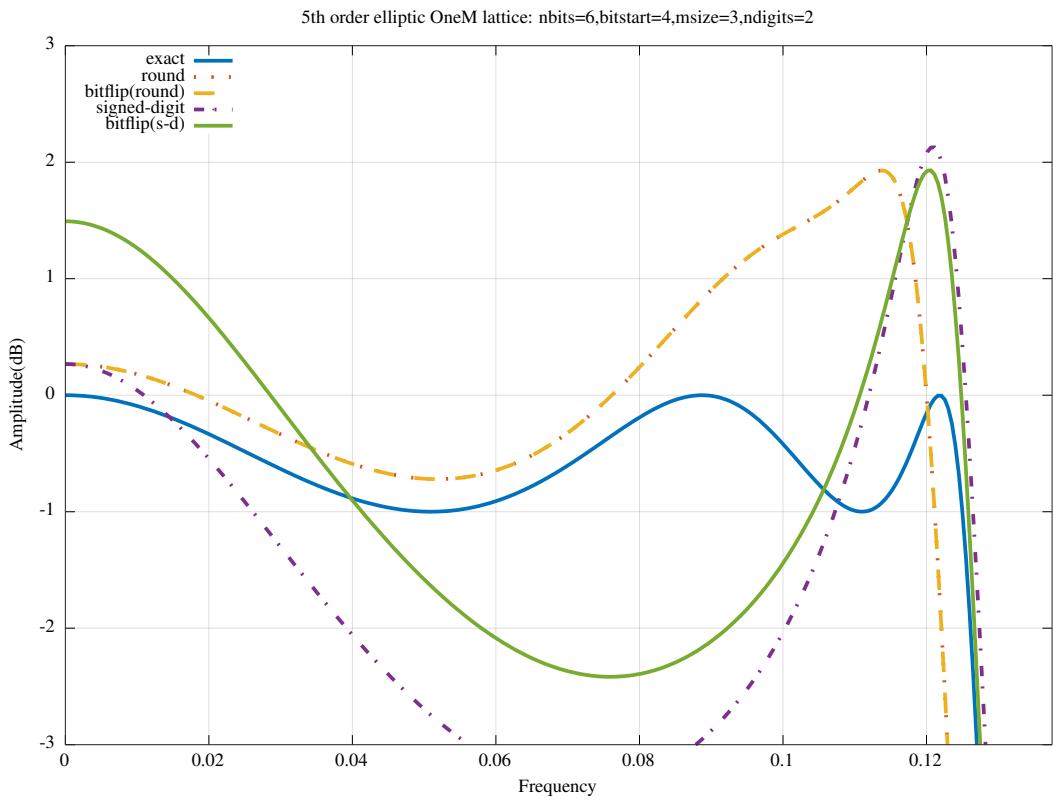

Figure 17.4: Pass-band amplitude response of the 5th order elliptic low-pass filter synthesised as a one multiplier lattice filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm, 6 bit 2 signed-digit coefficients, and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm

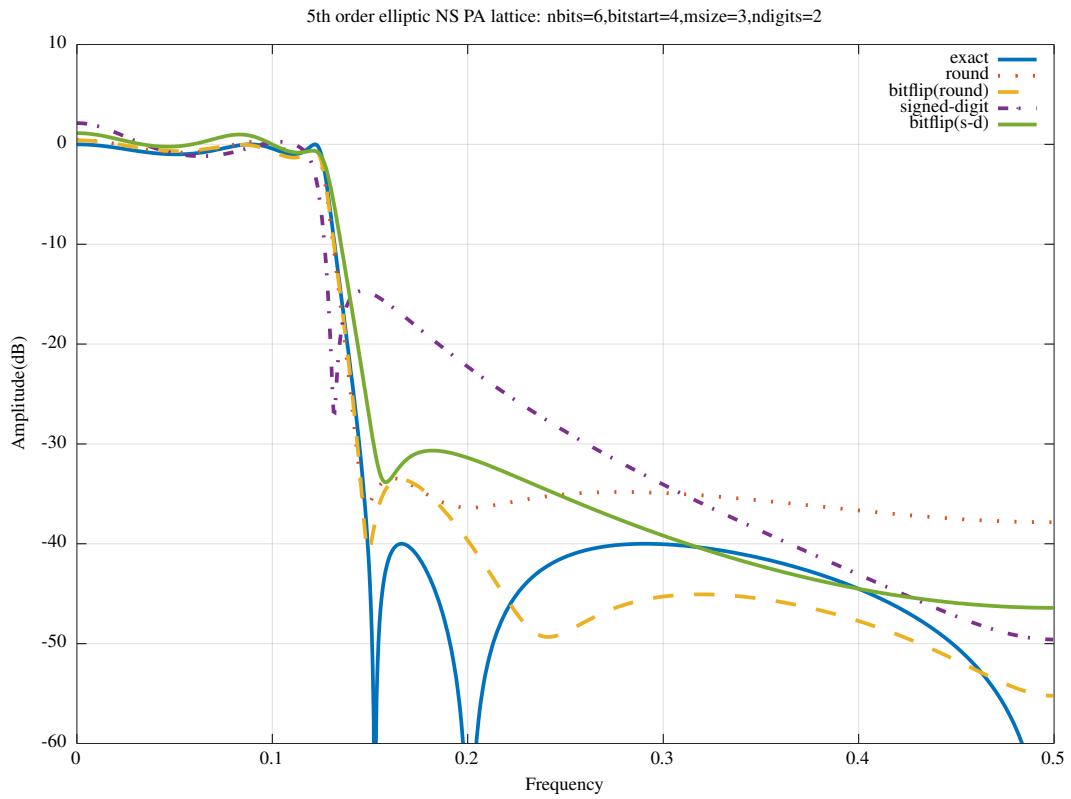

Figure 17.5: Amplitude response of the 5th order elliptic low-pass filter synthesised as parallel all-pass normalised-scaled lattice filters with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm, 6 bit 2 signed-digit coefficients, and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm

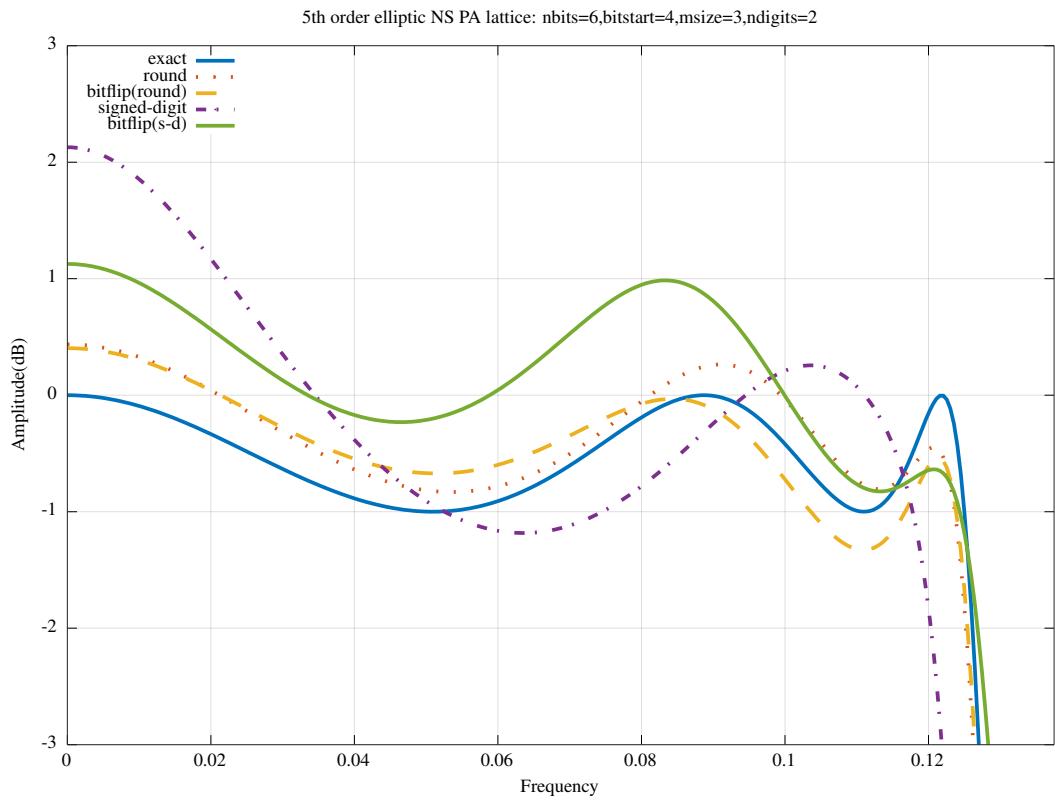

Figure 17.6: Pass-band amplitude response of the 5th order elliptic low-pass filter synthesised as parallel all-pass normalised-scaled lattice filters with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm, 6 bit 2 signed-digit coefficients, and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm

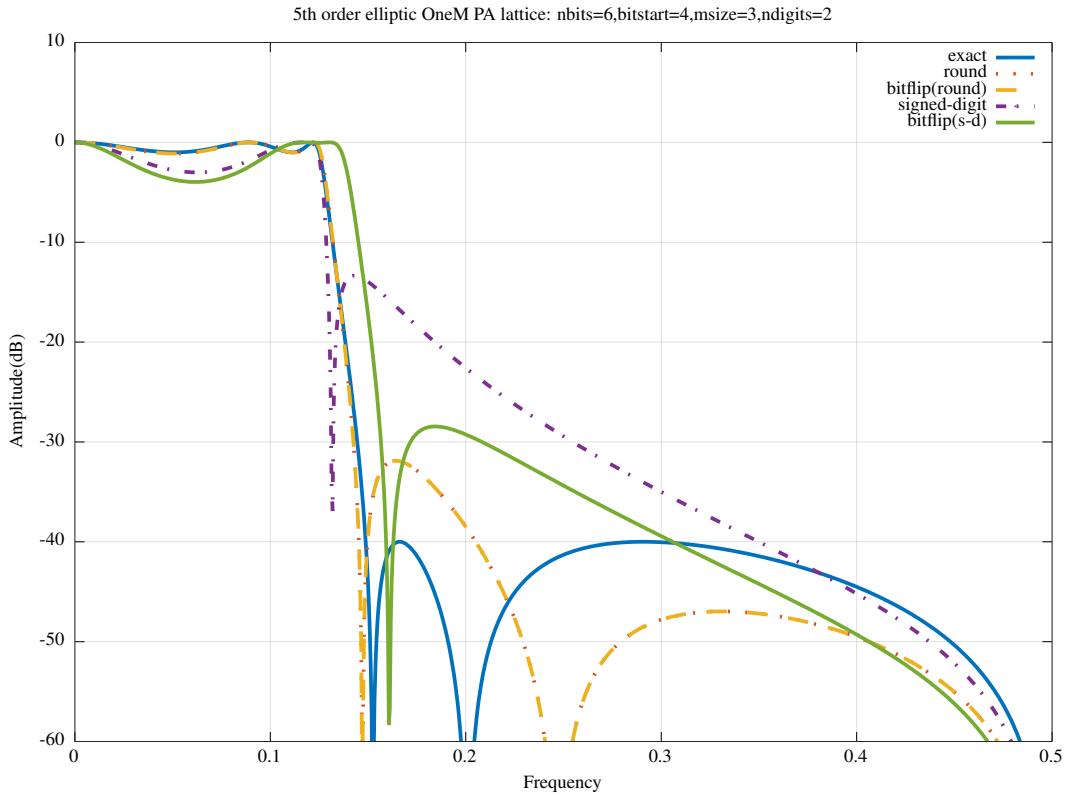

Figure 17.7: Amplitude response of the 5th order elliptic low-pass filter synthesised as parallel all-pass one multiplier lattice filters with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm, 6 bit 2 signed-digit coefficients, and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm

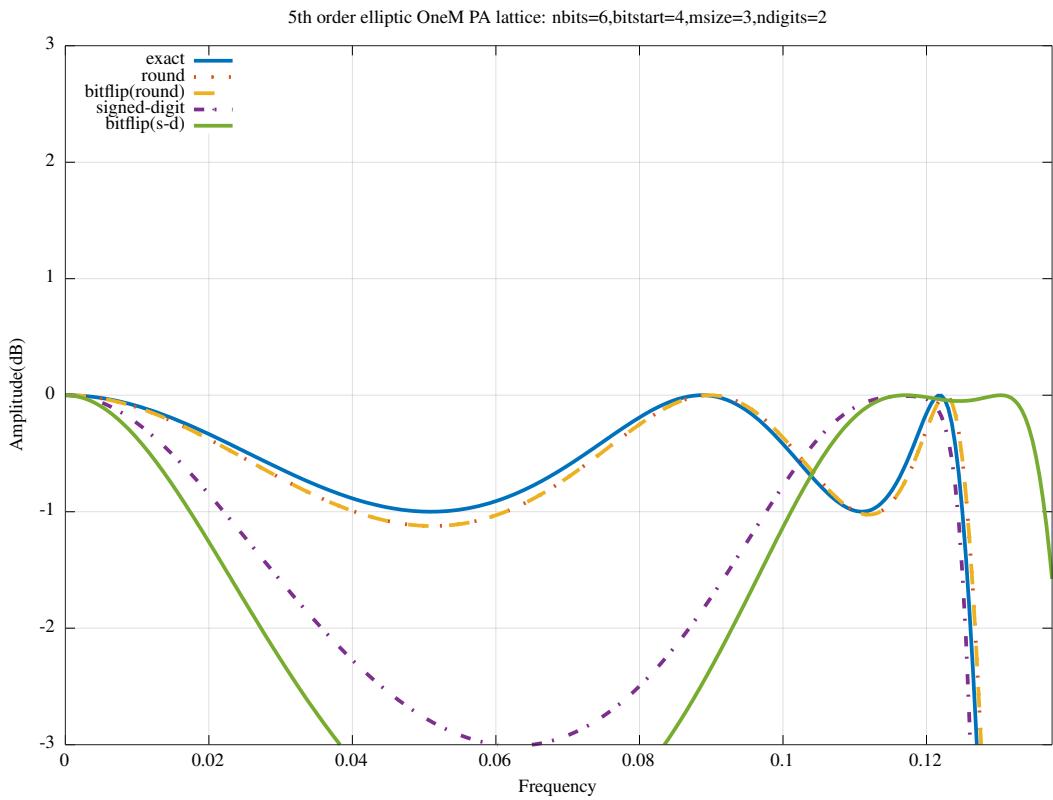

Figure 17.8: Pass-band amplitude response of the 5th order elliptic low-pass filter synthesised as parallel all-pass one multiplier lattice filters with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm, 6 bit 2 signed-digit coefficients, and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm

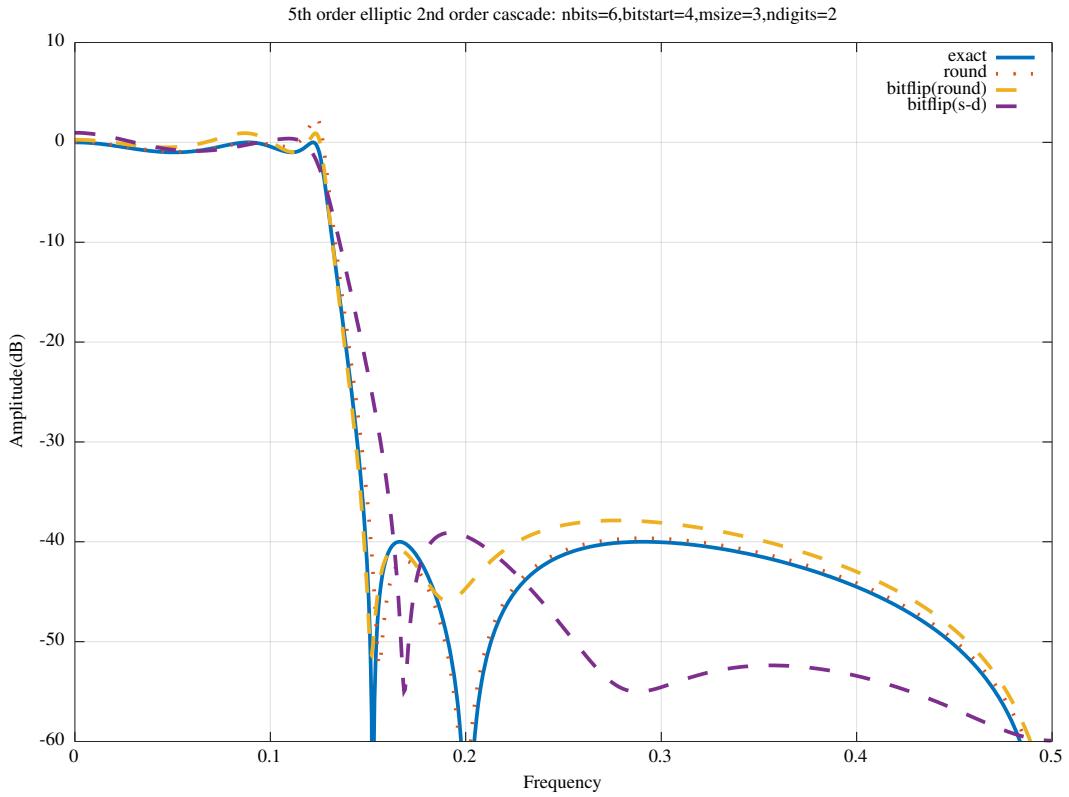

Figure 17.9: Amplitude response of the 5th order elliptic low-pass filter synthesised as a cascade of 2nd order state variable sections with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm

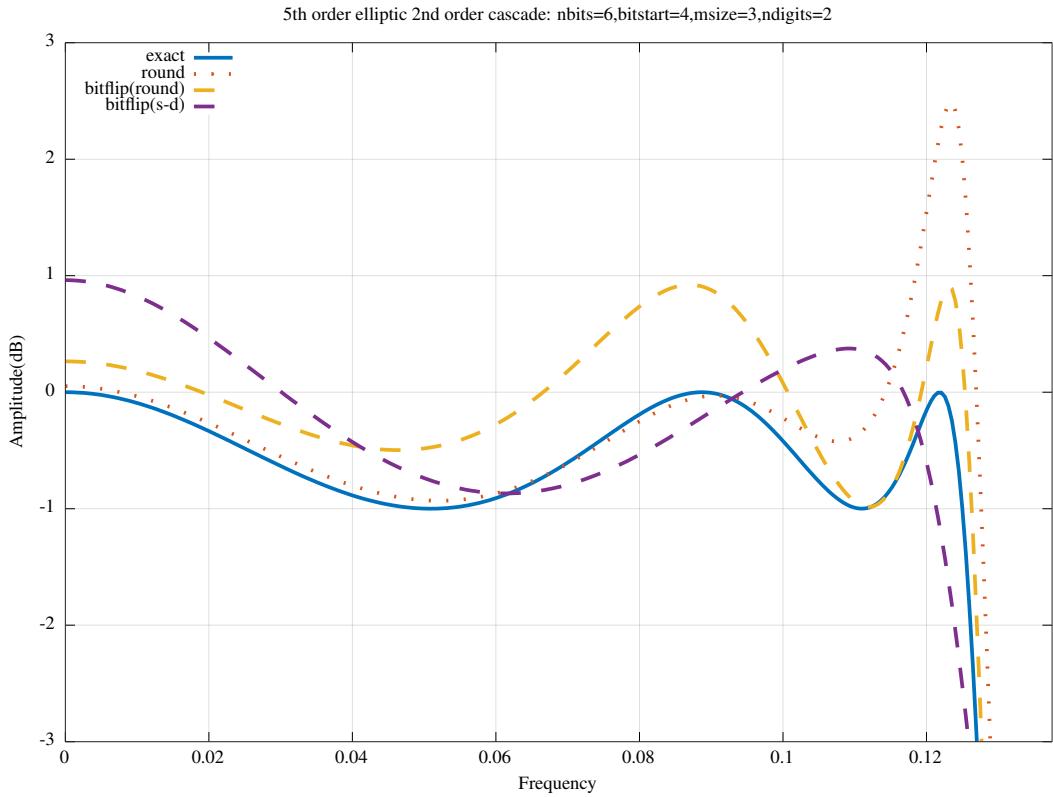

Figure 17.10: Pass-band amplitude response of the 5th order elliptic low-pass filter synthesised as a cascade of 2nd order state variable sections with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm and 6 bit 2 signed-digit coefficients optimised with the bit-flipping algorithm

17.2 Searching with the Nelder-Mead simplex algorithm

The Octave script *simplex_schurNSlattice_lowpass_test.m* implements the prototype elliptic filter as a normalised-scaled lattice and optimises the truncated coefficients with the *nelder_mead_min* simplex algorithm from the Octave-Forge *optim* package [102]. Figures 17.11 and 17.12 show the overall and passband responses of the prototype elliptic filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm. The cost function used with the signed-digit coefficients does not enforce the normalised-scaled orthogonal symmetry of $s_{00} = s_{22}$ and $s_{02} = -s_{20}$.

The Octave script *simplex_schurOneMlattice_lowpass_test.m* implements the 5th order elliptic filter as a one-multiplier lattice and optimises the truncated coefficients with the simplex algorithm. Figures 17.13 and 17.14 show the overall and passband responses of the filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm. The one-multiplier lattice state scaling coefficients are not truncated.

The Octave script *simplex_schurNSPA_lattice_lowpass_test.m* implements the 5th order elliptic filter as the sum of two normalised scaled all-pass lattice filters and optimises the truncated coefficients with the simplex algorithm. Figures 17.15 and 17.16 show the overall and passband responses of the parallel all-pass filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm. The cost function used with the signed-digit coefficients does not enforce the normalised-scaled orthogonal symmetry of $s_{00} = s_{22}$ and $s_{02} = -s_{20}$.

The Octave script *simplex_schurOneMPA_lattice_lowpass_test.m* implements the 5th order elliptic filter as the sum of two one-multiplier all-pass lattice filters and optimises the truncated coefficients with the simplex algorithm. Figures 17.17 and 17.18 show the overall and passband responses of the parallel all-pass filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm. The one-multiplier lattice state scaling coefficients are not truncated.

Finally, the Octave script *simplex_svccasc_lowpass_test.m* implements the 5th order elliptic filter as a pair of 2nd order minimum-noise state variable sections followed by a 1st order state variable section. (See Section 4). The script optimises the truncated coefficients with the simplex algorithm. Figures 17.19 and 17.20 show the overall and passband responses of the filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm. Note that the 2nd order state variable cascade filter obtained by simply converting the exact coefficients to 6 bit 2 signed-digit coefficients is unstable.

Table 17.2 compares the cost result for each test of the simplex algorithm.

Cost	Normalised-scaled lattice	One-multiplier lattice	Normalised-scaled PA lattice	One-multiplier PA lattice	2nd Order cascade
Exact	1.0008	1.0008	1.0008	1.0008	1.0008
Rounded	1.5432	1.5299	1.2459	1.1097	1.2362

Signed-digit	2.3373	2.7157	3.6059	3.9013	∞
Signed-digit with simplex	1.6581	2.3918	3.2559	3.1746	3.2134

Table 17.2: Summary of the cost results for the example 5th order elliptic low-pass filter synthesised as a normalised-scaled or one-multiplier lattice filter or as a cascade of 2nd order state variable sections with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm

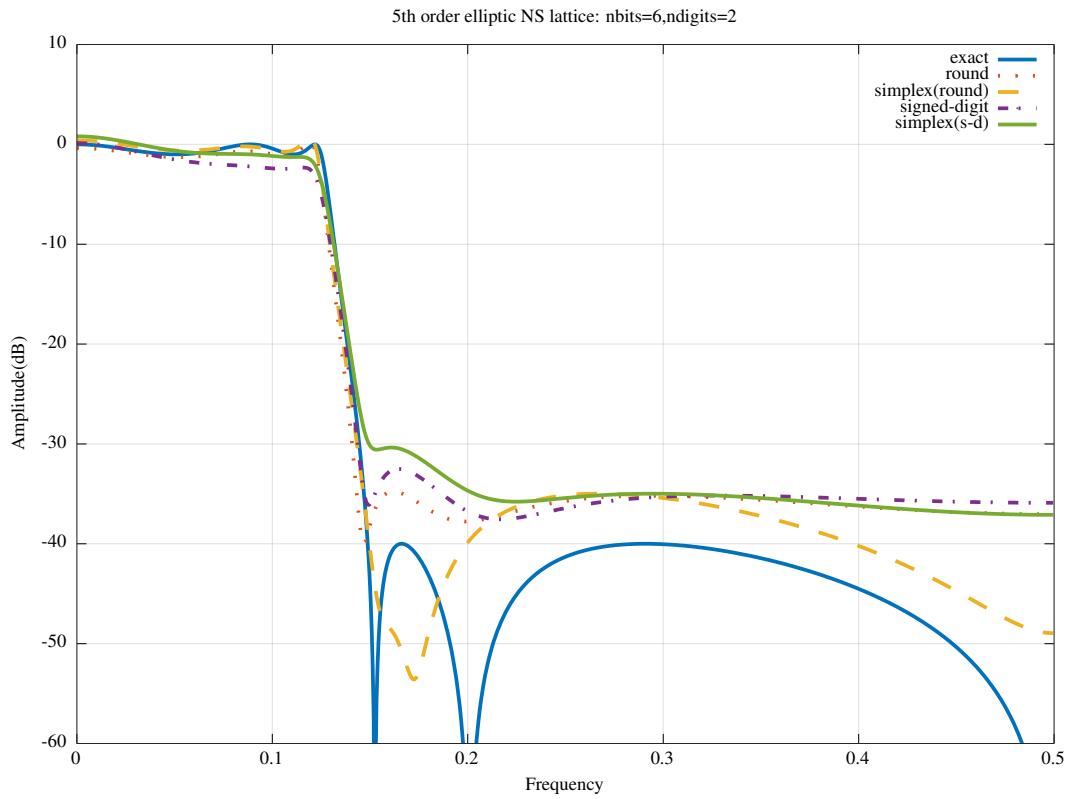

Figure 17.11: Amplitude response of the 5th order elliptic low-pass filter synthesised as a normalised-scaled lattice filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm

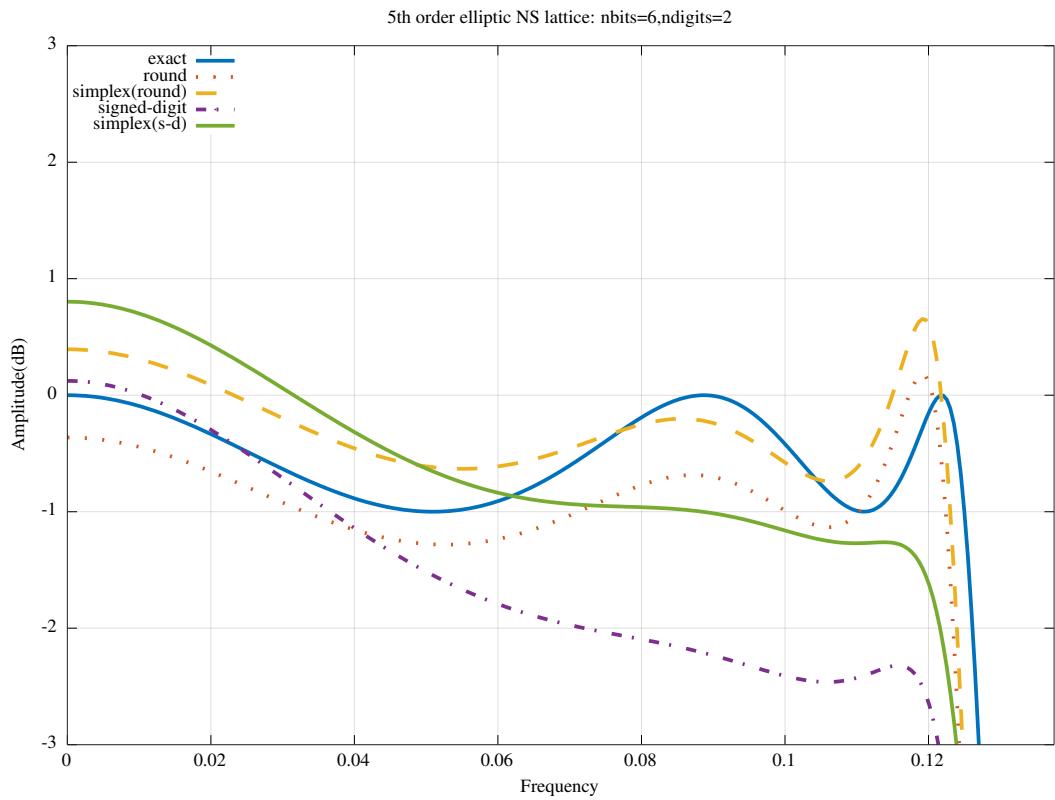

Figure 17.12: Pass-band amplitude response of the 5th order elliptic low-pass filter synthesised as a scaled=normalised lattice filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm

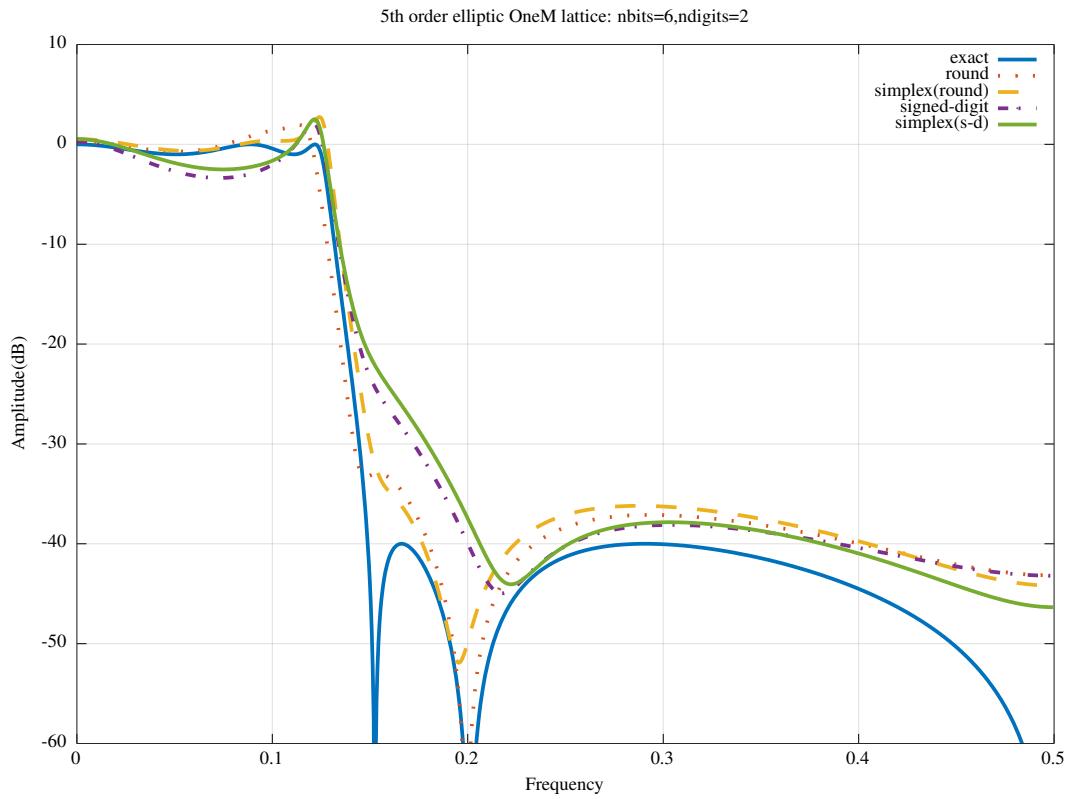

Figure 17.13: Amplitude response of the 5th order elliptic low-pass filter synthesised as a one multiplier lattice filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm

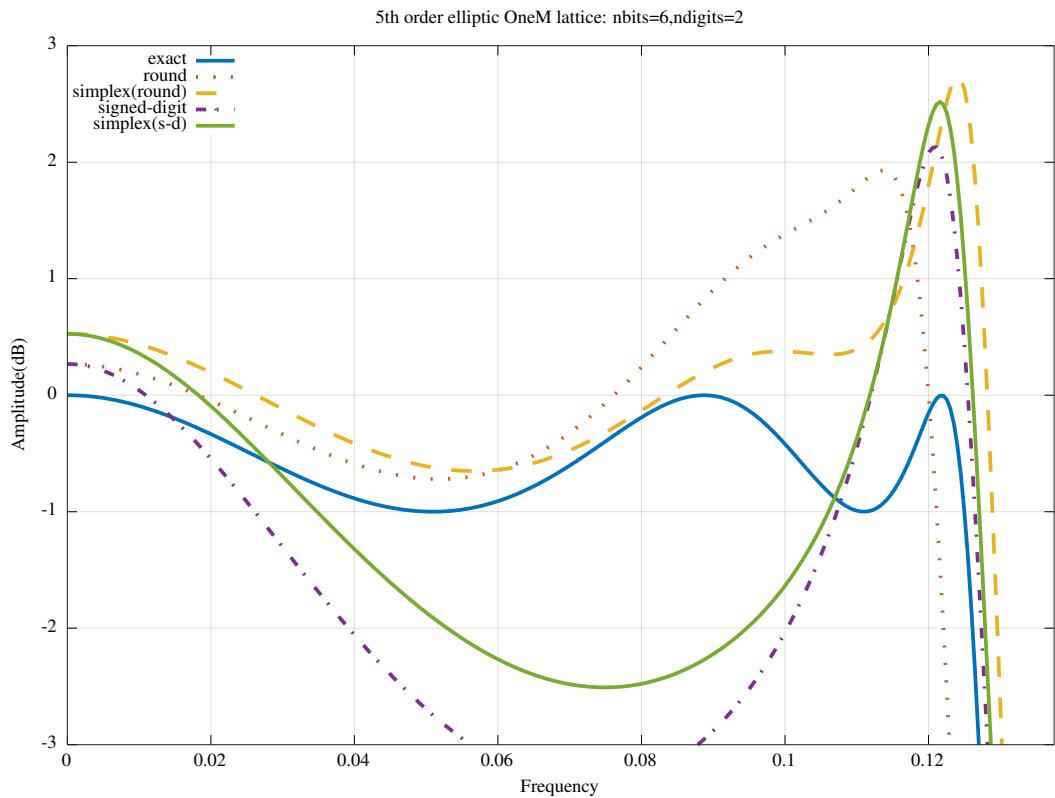

Figure 17.14: Pass-band amplitude response of the 5th order elliptic low-pass filter synthesised as a one multiplier lattice filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm

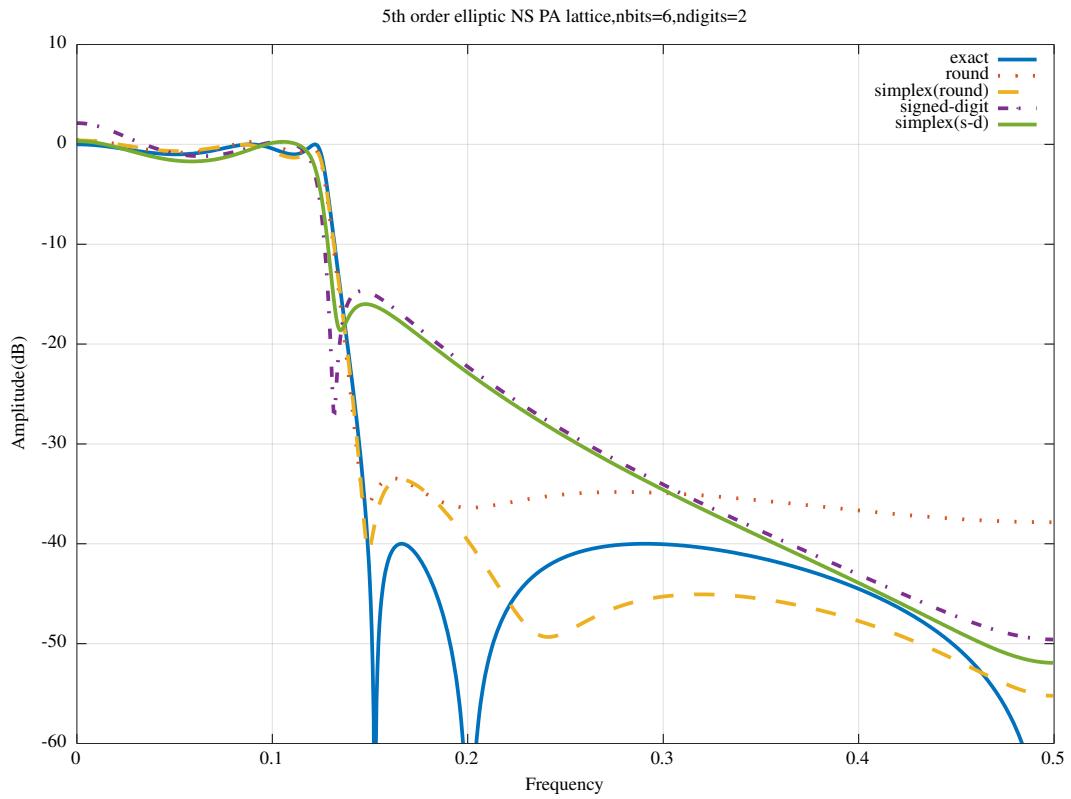

Figure 17.15: Amplitude response of the 5th order elliptic low-pass filter synthesised as parallel all-pass normalised-scaled lattice filters with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm

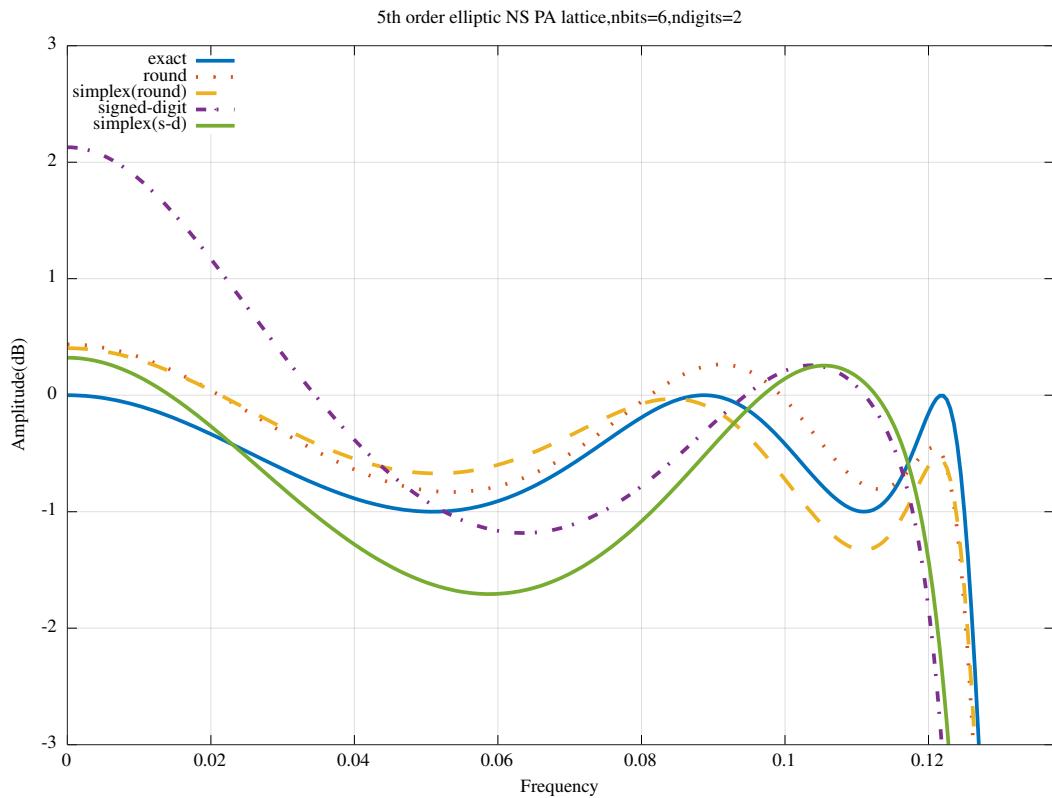

Figure 17.16: Pass-band amplitude response of the 5th order elliptic low-pass filter synthesised as parallel all-pass normalised-scaled lattice filters with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm

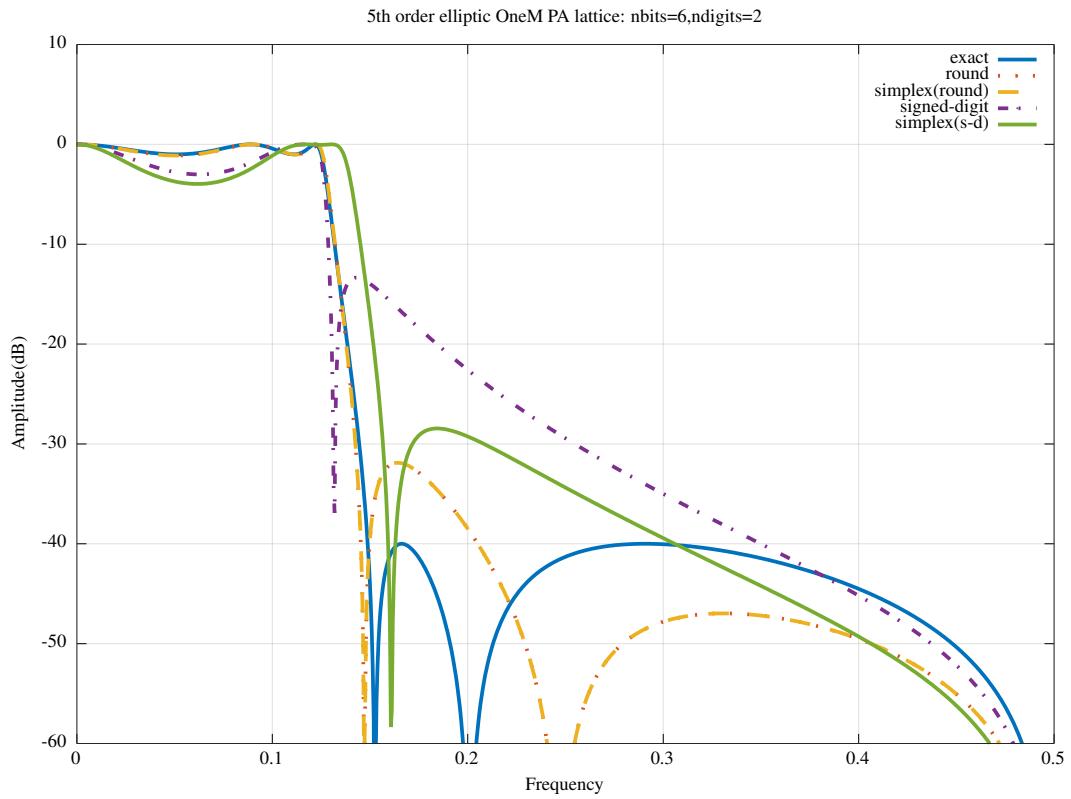

Figure 17.17: Amplitude response of the 5th order elliptic low-pass filter synthesised as parallel all-pass one multiplier lattice filters with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm

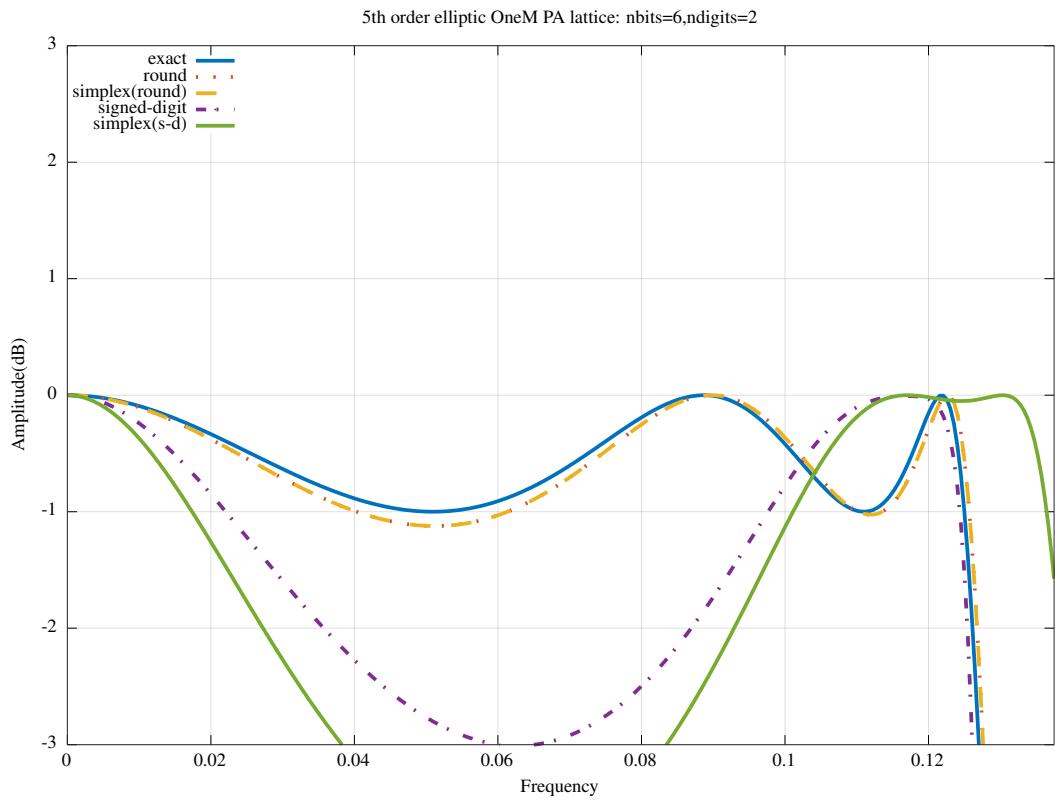

Figure 17.18: Pass-band amplitude response of the 5th order elliptic low-pass filter synthesised as parallel all-pass one multiplier lattice filters with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm

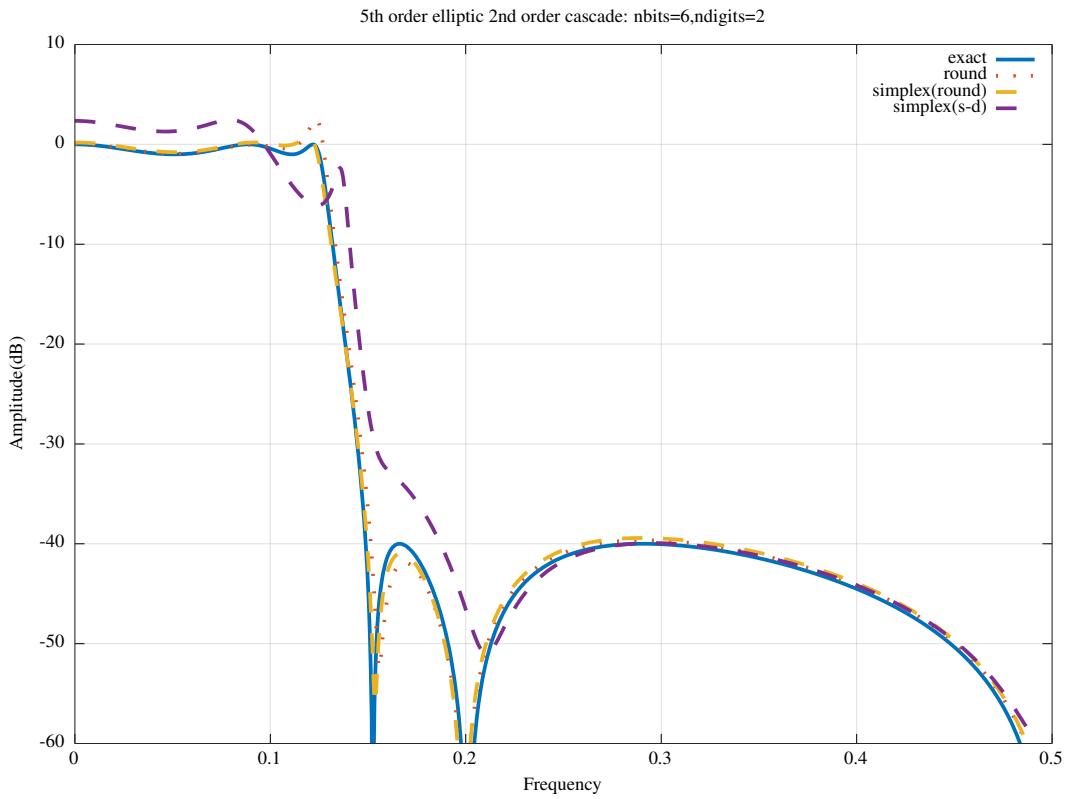

Figure 17.19: Amplitude response of the 5th order elliptic low-pass filter synthesised as a cascade of 2nd order state variable sections with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm

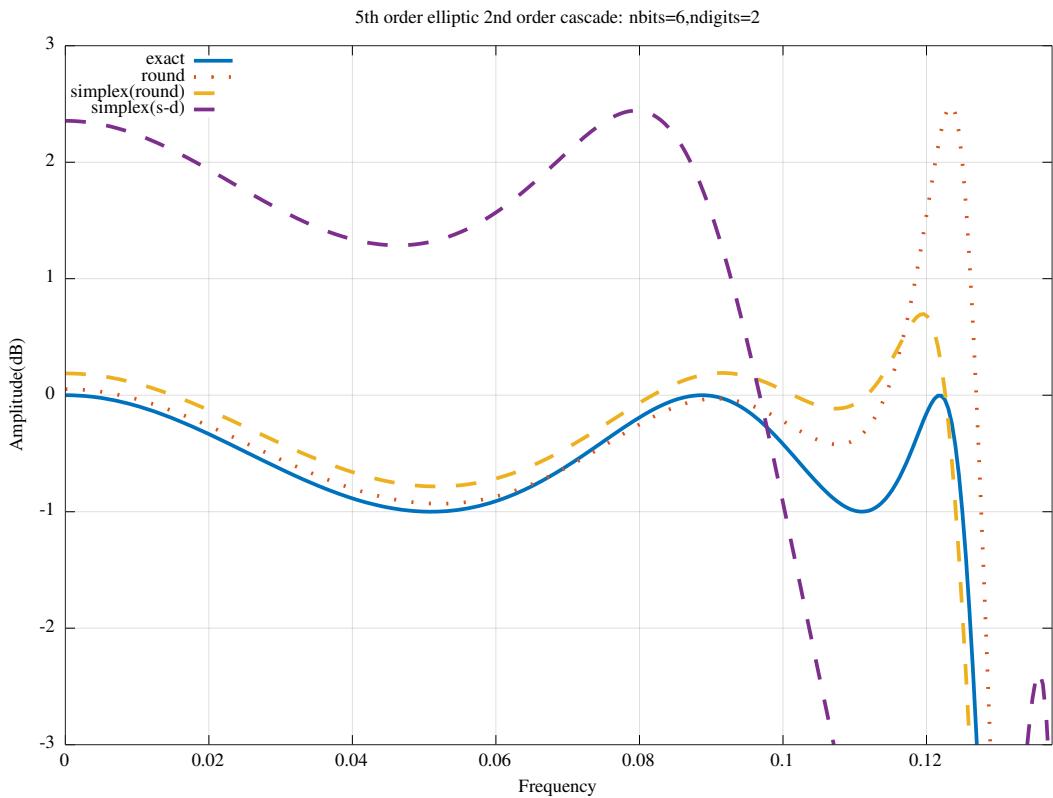

Figure 17.20: Pass-band amplitude response of the 5th order elliptic low-pass filter synthesised as a cascade of 2nd order state variable sections with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simplex algorithm and 6 bit 2 signed-digit coefficients optimised with the simplex algorithm

17.3 Searching with the *simulated annealing* algorithm

This section shows the results of searching for the coefficients of a 5-th order low-pass filter with the Octave-Forge *optim* package [102] implementation of the simulated annealing algorithm, *samin*. Unfortunately, the minimum cost found by *samin* may vary by a factor of 2 or more from run to run. In this section I show the best results from 10 runs of each test.

The Octave script *samin_schurNSlattice_lowpass_test.m* implements the prototype elliptic filter as a normalised-scaled lattice and optimises the truncated coefficients with the *samin* simulated annealing algorithm from the Octave-Forge *optim* package [102]. Figures 17.21 and 17.22 show, for the best results from 10 runs, the overall and passband responses of the prototype elliptic filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simulated annealing algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simulated annealing algorithm. The cost function used with the signed-digit coefficients does not enforce the normalised-scaled orthogonal symmetry of $s_{00} = s_{22}$ and $s_{02} = -s_{20}$.

The Octave script *samin_schurOneMlattice_lowpass_test.m* implements the prototype elliptic filter as a one-multiplier lattice and optimises the truncated coefficients with the simulated annealing algorithm. Figures 17.23 and 17.24 show, for the best results from 10 runs, the overall and passband responses of the prototype elliptic filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simulated annealing algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simulated annealing algorithm. The one multiplier lattice state scaling coefficients are not truncated.

The Octave script *samin_schurNSPA_lattice_lowpass_test.m* implements the 5th order elliptic filter as the sum of two normalised-scaled all-pass lattice filters and optimises the truncated coefficients with the simulated annealing algorithm. Figures 17.25 and 17.26 show, for the best results from 10 runs, the overall and passband responses of the prototype elliptic filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simulated annealing algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simulated annealing algorithm. The cost function used with the signed-digit coefficients does not enforce the normalised-scaled orthogonal symmetry of $s_{00} = s_{22}$ and $s_{02} = -s_{20}$.

The Octave script *samin_schurOneMPAlattice_lowpass_test.m* implements the 5th order elliptic filter as the sum of two one-multiplier all-pass lattice filters and optimises the truncated coefficients with the simulated annealing algorithm. Figures 17.27 and 17.28 show, for the best results from 10 runs, the overall and passband responses of the prototype elliptic filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the simulated annealing algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the simulated annealing algorithm. The one multiplier lattice state scaling coefficients are not truncated.

Finally, the Octave script *samin_svccasc_lowpass_test.m* implements the 5th order elliptic filter as a pair of 2nd order minimum-noise state variable sections followed by a 1st order state variable section. (See Section 4). The script optimises the truncated coefficients with the simulated annealing algorithm. Figures 17.29 and 17.30 show the overall and passband responses of the filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm and 6 bit 2 signed-digit coefficients optimised with the simulated annealing algorithm. Note that the 2nd order state variable cascade filter obtained by simply converting the exact coefficients to 6 bit 2 signed-digit coefficients is unstable.

Table 17.3 shows the minimum cost result for 10 runs of each test.

17.4 Searching with the *differential evolution* algorithm

This section shows the results of searching for the coefficients of a 5-th order low-pass filter with the Octave-Forge *optim* package [102] implementation of the *differential evolution* algorithm of Storn and Price [135], *de_min*. Unfortunately, the minimum cost found by *de_min* may vary from run to run. In this section I show the best results from 10 runs of each test. These tests use the default control settings for *de_min*.

The Octave script *de_min_schurNSlattice_lowpass_test.m* implements the prototype elliptic filter as a normalised-scaled lattice and optimises the truncated coefficients with the *de_min* differential evolution algorithm from the Octave-Forge *optim* package [102]. Figures 17.31 and 17.32 show, for the best results from 10 runs, the overall and passband responses of the prototype elliptic filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the differential evolution algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the differential evolution algorithm. The cost function used with the signed-digit coefficients does not enforce the normalised-scaled orthogonal symmetry of $s_{00} = s_{22}$ and $s_{02} = -s_{20}$.

The Octave script *de_min_schurOneMlattice_lowpass_test.m* implements the prototype elliptic filter as a one-multiplier lattice and optimises the truncated coefficients with the differential evolution algorithm. Figures 17.33 and 17.34 show, for the best results from 10 runs, the overall and passband responses of the prototype elliptic filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the differential evolution algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the differential evolution algorithm. The one multiplier lattice state scaling coefficients are not truncated.

The Octave script *de_min_schurNSPA_lattice_lowpass_test.m* implements the 5th order elliptic filter as the sum of two normalised-scaled all-pass lattice filters and optimises the truncated coefficients with the differential evolution algorithm. Figures 17.35 and 17.36 show, for the best results from 10 runs, the overall and passband responses of the prototype elliptic filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the differential evolution algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the differential evolution algorithm. The cost function used with the signed-digit coefficients does not enforce the normalised-scaled orthogonal symmetry of $s_{00} = s_{22}$ and $s_{02} = -s_{20}$.

The Octave script *de_min_schurOneMPA_lattice_lowpass_test.m* implements the 5th order elliptic filter as the sum of two one-multiplier all-pass lattice filters and optimises the truncated coefficients with the differential evolution algorithm. Figures 17.37 and 17.38 show, for the best results from 10 runs, the overall and passband responses of the prototype elliptic filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the differential evolution algorithm, 6 bit 2 signed-digit coefficients and 6 bit 2 signed-digit coefficients optimised with the differential evolution algorithm. The one multiplier lattice state scaling coefficients are not truncated.

Finally, the Octave script *de_min_svccasc_lowpass_test.m* implements the 5th order elliptic filter as a pair of 2nd order minimum-noise state variable sections followed by a 1st order state variable section. (See Section 4). The script optimises the truncated coefficients with the differential evolution algorithm. Figures 17.39 and 17.40 show the overall and passband responses of the filter with exact coefficients, 6 bit rounded coefficients, 6 bit rounded coefficients optimised with the bit-flipping algorithm and 6 bit 2 signed-digit coefficients optimised with the differential evolution algorithm. Note that the 2nd order state variable cascade filter obtained by simply converting the exact coefficients to 6 bit 2 signed-digit coefficients is unstable.

Table 17.4 shows the minimum cost result for 10 runs of each test.

17.5 Summary of the search algorithm comparison

Table 17.5 compares the cost result for each of the search algorithms. The relative time consumed by the algorithms is, in increasing order: simplex, bit-flipping, differential evolution and simulated annealing. The simulated annealing and differential evolution costs shown are the minimum found for 10 runs of the corresponding test script.

Cost	Normalised-scaled lattice	One-multiplier lattice	Normalised-scaled PA lattice	One-multiplier PA lattice	2nd Order cascade

Review of Complex Variables

This chapter summarises Kreyszig [33, Chapter 12(Sections 4 and 5), Chapter 14].

A.1 Complex Functions

Define a function f on the complex numbers, \mathbb{C} , $w = f(z)$, where z varies in S and is called a “*complex variable*”. S is called the *domain* of z and the set of complex numbers, w , that $f(z)$ assumes is called the *range* of $f(z)$. Write the real and imaginary parts of w in terms of the real and imaginary parts of $z = x + iy$ as $w = f(z) = u(x, y) + iv(x, y)$ where u and v are real valued functions of the real variables x and y and, of course, $i = \sqrt{-1}$.

A.2 Limit

A function $f(z)$ is said to have a limit ℓ as z approaches $w = f(z) = u(x, y) + iv(x, y)$ if $f(z)$ is defined in a neighbourhood of z_0 (except perhaps at z_0 itself) and if for any positive, non-zero real number ϵ we can find a real positive δ such that, for all $z \neq z_0$ in the disk $|z - z_0| < \delta$, $|f(z) - \ell| < \epsilon$. We write:

$$\lim_{z \rightarrow z_0} f(z) = \ell$$

A function $f(z)$ is *continuous* at $z = z_0$ if $f(z_0)$ is defined and

$$\lim_{z \rightarrow z_0} f(z) = f(z_0)$$

A function $f(z)$ is *differentiable* at $z = z_0$ if the limit

$$f'(z) = \lim_{z \rightarrow z_0} \frac{f(z_0 + \Delta z) - f(z_0)}{\Delta z}$$

exists. This limit is called the *derivative* of $f(z)$ at $z = z_0$. $f(z)$ is said to be *analytic* (or *holomorphic*) in a domain D , if $f(z)$ is defined and differentiable at all points of D . For example, $f(z) = x - iy$ is not differentiable. If $\Delta z = \Delta x + i\Delta y$ then:

$$\frac{f(z + \Delta z) - f(z)}{\Delta z} = \frac{\Delta x - i\Delta y}{\Delta x + i\Delta y}$$

If Δz approaches z with $\Delta y = 0$ then the derivative is -1 but if Δz approaches z with $\Delta x = 0$ then the derivative is 1 . Hence the limit approaches different values along different paths to $z = x + iy$.

A.3 The Cauchy-Riemann Equations

Suppose $f(z) = u(x, y) + iv(x, y)$ is defined and continuous within a neighbourhood of an arbitrary fixed point z and differentiable at z so that $f'(z)$ exists. Set $\Delta z = \Delta x + i\Delta y$. On a path for which Δz approaches z with $\Delta y = 0$, then:

$$f'(z) = \lim_{\Delta x \rightarrow 0} \frac{u(x + \Delta x, y) - u(x, y)}{\Delta x} + i \lim_{\Delta x \rightarrow 0} \frac{v(x + \Delta x, y) - v(x, y)}{\Delta x}$$

$$= \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x}$$

Similarly, for a path on which Δz approaches z with $\Delta x = 0$

$$f'(z) = \frac{\partial v}{\partial y} - i \frac{\partial u}{\partial y}$$

Equating real and imaginary parts, we obtain the Cauchy-Riemann equations

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}$$

and

$$\frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}$$

If $f(z) = u(x, y) + iv(x, y)$ is analytic in D then the real and imaginary parts of f satisfy Laplace's equation in D and have continuous second partial derivatives in D

$$\nabla^2 u = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

and

$$\nabla^2 v = 0$$

A.4 Line integrals in the complex plane

Let C be a smooth curve in the z plane with $z(t) = x(t) + iy(t)$ with $a \leq t \leq b$ where $z(t)$ has a continuous derivative $\dot{z}(t) \neq 0$ for all t . Let $f(z)$ be a continuous function defined at each point of C . Divide the interval $a \leq t \leq b$ into sub-intervals $t_0 = a \leq t_1 \leq \dots \leq t_n = b$ corresponding to $z_0 = z(t_0), z_1, \dots, z_n = z(t_n)$. For each sub-interval of C choose an arbitrary point, ζ_i , between z_{i-1} and z_i . Then form the sums

$$S_n = \sum_{i=1}^n f(\zeta_i) \Delta z_i$$

where $\Delta z_i = z_i - z_{i-1}$. Define $\zeta_i = \varepsilon_i + i\eta_i$ and $\Delta z_i = \Delta x_i + i\Delta y_i$ and let $f(z) = u(x, y) + iv(x, y)$. Then S_n consists of four real sums

$$\begin{aligned} S_n &= \sum_{i=1}^n (u + iv)(\Delta x_i + i\Delta y_i) \\ &= \sum_{i=1}^n u\Delta x_i - \sum_{i=1}^n v\Delta y_i + i \left[\sum_{i=1}^n u\Delta y_i + \sum_{i=1}^n v\Delta x_i \right] \end{aligned}$$

and the *line integral* of $f(z)$ along C is defined as the limit of the sums S_n and

$$\begin{aligned} \int_C f(z) dz &= \lim_{n \rightarrow \infty} S_n \\ &= \int_C u dx - \int_C v dy + i \left[\int_C u dy + \int_C v dx \right] \\ &= \int_a^b u \dot{x} dt - \int_a^b v \dot{y} dt + i \left[\int_a^b u \dot{y} dt + \int_a^b v \dot{x} dt \right] \\ &= \int_C f[z(t)] \dot{z} dt \end{aligned}$$

The absolute value of the line integral is bounded by

$$\left| \int_C f(z) dz \right| \leq Ml$$

where l is the length of the path C and M is a real constant such that $|f(z)| \leq M$ everywhere on the path C .

A.5 Cauchy's Integral Theorem

A domain D in the complex plane is called *simply connected* if every simple closed curve in D encloses only points in D . Such a domain D is said to be *bounded* if D lies entirely within a circle about the origin. If $f(z)$ is analytic in a simply connected bounded domain D then for each simple closed path C in D

$$\oint_C f(z) dz = 0$$

PROOF: Cauchy made the additional assumption that $f'(z)$ is continuous and applied Green's theorem. Write

$$\oint_C f(z) dz = \int_C u dx - v dy + i \int_C u dy + v dx$$

$f(z)$ is analytic so $f'(z)$ exists. For the real part, using the Cauchy-Riemann equations, by Green's theorem

$$\begin{aligned} \int_C u dx - v dy &= \iint_R \left[-\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right] dx dy \\ &= 0 \end{aligned}$$

where R is the region bounded by C . Similarly for the imaginary part. Goursat provided a proof that does not require $f'(z)$ to be continuous. A corollary of Cauchy's Integral theorem is that the line integral of $f(z)$ is independent of the path in D .

A.6 Cauchy's Integral Formula

Let $f(z)$ be analytic in a simply connected domain, D . Then for any point z_0 in D and any simple closed path C in D which encloses z_0

$$\oint_C \frac{f(z)}{z - z_0} dz = 2\pi i f(z_0)$$

PROOF: Let

$$f(z) = f(z_0) + [f(z) - f(z_0)]$$

so

$$\oint_C \frac{f(z)}{z - z_0} dz = f(z_0) \oint_C \frac{dz}{z - z_0} + \oint_C \frac{f(z) - f(z_0)}{z - z_0} dz$$

For the first term use the identity

$$\int_c (z - z_0)^m dz = \begin{cases} 2\pi i & m = -1 \\ 0 & m \neq -1, \text{ integral} \end{cases}$$

found by setting $z(t) = z_0 + \rho e^{it}$ and integrating over t . For the second term, replace C by a small circle K , with centre z_0 . $f(z)$ is analytic so for any $\epsilon > 0$ we can find a $\delta > 0$ so that $|f(z) - f(z_0)| < \epsilon$ for all z in $|z - z_0| < \delta$. Choose the radius ρ of K smaller than δ then

$$\left| \frac{f(z) - f(z_0)}{z - z_0} \right| < \frac{\epsilon}{\rho}$$

at each point of K . Since the length of K is $2\pi\rho$

$$\left| \int_K \frac{f(z) - f(z_0)}{z - z_0} dz \right| < 2\pi\epsilon$$

at each point of K and the second term is shown to be zero.

A.7 Derivatives of an analytic function

If $f(z)$ is analytic in D then it has derivatives of all orders in D which are also analytic functions in D

$$f^{(n)}(z_0) = \frac{n!}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^{n+1}} dz, n = 1, 2, \dots$$

PROOF: For $f'(z_0)$

$$f'(z_0) = \lim_{\Delta z \rightarrow 0} \frac{f(z_0 + \Delta z) f(z_0)}{\Delta z}$$

Applying Cauchy's Integral formula

$$\begin{aligned} f'(z_0) &= \lim_{\Delta z \rightarrow 0} \frac{1}{2\pi i \Delta z} \left[\int_C \frac{f(z)}{z - (z_0 + \Delta z)} dz - \int_C \frac{f(z)}{z - z_0} dz \right] \\ &= \frac{1}{2\pi i} \int_C \frac{f(z)}{(z - z_0)^2} dz + \lim_{\Delta z \rightarrow 0} \frac{\Delta z}{2\pi i} \int_C \frac{f(z)}{(z - z_0 - \Delta z)(z - z_0)^2} dz \end{aligned}$$

So we need to establish that the second term on the right is zero. On C the function $f(z)$ is continuous. Hence $f(z)$ is bounded in absolute value on C , say $|f(z)| < M$. Let d be the distance of the point or points of C which are closest to z_0 . Then for all z on C , $|z - z_0| \geq d$ hence $|z - z_0|^{-1} \leq \frac{1}{d}$. Also, if $|\Delta z| \leq \frac{d}{2}$, then for all z on C we have the inequality $|z - z_0 - \Delta z| \geq \frac{d}{2}$ hence $|z - z_0 - \Delta z|^{-1} \leq \frac{2}{d}$. Denoting the length of C by L

$$\left| \frac{\Delta z}{2\pi i} \int_C \frac{f(z)}{(z - z_0 - \Delta z)(z - z_0)^2} dz \right| < \frac{|\Delta z|}{2\pi} \frac{M}{\frac{1}{2}dd^2} L$$

As Δz approaches zero the right hand side approaches zero. The general formula follows by induction.

A.8 Laurent's Theorem

If $f(z)$ is analytic on two concentric circles with centre a and in the annulus between them, then $f(z)$ can be represented by the *Laurent series*

$$f(z) = \sum_{n=0}^{\infty} b_n (z - a)^n + \sum_{n=1}^{\infty} \frac{c_n}{(z - a)^n}$$

where

$$\begin{aligned} b_n &= \frac{1}{2\pi i} \oint_C \frac{f(z^*)}{(z^* - a)^{n+1}} dz^* \\ c_n &= \frac{1}{2\pi i} \oint_C (z^* - a)^{n-1} f(z^*) dz^* \end{aligned}$$

each integral being taken in the counter-clockwise direction around any simple closed path, C , which lies in the annulus and encloses the inner circle. This series converges and represents $f(z)$ in the open annulus obtained from the given annulus by continuously increasing the circle C_1 and decreasing C_2 until each if the two circles reaches a point where $f(z)$ is singular.

For a proof see Kreyszig [33, Section 16.7]. A common case occurs when $z = a$ is the only singular point of $f(z)$ in C_2 . Then the Laurent expansion converges for all z in C_1 except at $z = a$.

A.9 Residues

If $f(z)$ is analytic in the neighbourhood of a point $z = a$, then by Cauchy's integral theorem

$$\oint_C f(z) dz = 0$$

for any closed path, C , in that neighbourhood. If, however, $f(z)$ has an isolated singularity at $z = a$ and a lies in the interior of C , then we may represent $f(z)$ by the Laurent series

$$f(z) = \sum_{n=0}^{\infty} b_n (z-a)^n + \frac{c_1}{(z-a)} + \frac{c_2}{(z-a)^2} + \dots$$

which converges on the domain $0 < |z - a| < R$. Consequently

$$\oint_C f(z) dz = 2\pi i c_1$$

c_1 is called the *residue* of $f(z)$ at $z = a$. The integral of $f(z)$ over C can be extended to paths that contain finitely many singular points.

A.10 Cauchy's Argument Principle

A *meromorphic* function on an open subset, D , of the complex plane is a function that is holomorphic on all D except at a set of isolated points (the *poles* of the function) at which it must have a Laurent series. If $f(z)$ is a meromorphic function inside and on a closed contour, C , and has no poles or zeros on C , then

$$\oint_C \frac{f'(z)}{f(z)} dz = 2\pi i (k - m)$$

where k and m denote the number of zeros and poles, respectively, of $f(z)$ inside C . Each zero and pole is counted as many times as its multiplicity and order, respectively, indicate.

PROOF: Let z_N be a zero of $f(z)$ with multiplicity k , then

$$f(z) = (z - z_N)^k g(z)$$

where $g(z_N) \neq 0$. Differentiating

$$f'(z) = k(z - z_N)^{k-1} g(z) + (z - z_N)^k g'(z)$$

and

$$\frac{f'(z)}{f(z)} = \frac{k}{z - z_N} + \frac{g'(z)}{g(z)}$$

Since $g(z_N) \neq 0$, $\frac{g'(z)}{g(z)}$ has no singularities and is analytic at z_N and the residue of $\frac{f'(z)}{f(z)}$ at z_N is k .

Similarly, let z_P be a pole of $f(z)$ with order k , then

$$f(z) = (z - z_P)^{-m} h(z)$$

where $h(z_P) \neq 0$. Differentiating

$$f'(z) = -m(z - z_P)^{-m-1} h(z) + (z - z_P)^{-m} h'(z)$$

and

$$\frac{f'(z)}{f(z)} = \frac{-m}{z - z_P} + \frac{h'(z)}{h(z)}$$

Since $h(z_P) \neq 0$, $\frac{h'(z)}{h(z)}$ has no singularities and is analytic at z_P and the residue of $\frac{f'(z)}{f(z)}$ at z_P is $-m$.

A.11 Rouché's Theorem

If $f(z)$ and $g(z)$ are analytic inside and on a closed contour C , and $|g(z)| < |f(z)|$ on C , then $f(z)$ and $f(z) + g(z)$ have the same number of zeros inside C .

Appendix B

Review of Legendre's elliptic integrals and Jacobi's elliptic functions

This appendix reviews the notation for *Legendre's elliptic integrals* and *Jacobi's elliptic functions*. See *Whittaker and Watson* [32, Chapters 20, 21 and 22] and the *NIST Digital Library of Mathematical Functions* [36, Chapters 19, 20 and 22]^a. *Vlček and Unbehauen* [95, Appendix] provide a brief review of the elliptic function theory required for IIR filter design.

B.1 Doubly periodic functions

Whittaker and Watson [32, Section 20.1] give the following definition of elliptic functions as doubly-periodic functions:

Let ω_1 and ω_2 be any two numbers whose ratio is not purely real. A function which satisfies the equations

$$\begin{aligned} f(z + 2\omega_1) &= f(z) \\ f(z + 2\omega_2) &= f(z) \end{aligned}$$

for all values of z for which $f(z)$ exists, is called a *doubly periodic* function of z , with periods $2\omega_1$ and $2\omega_2$. A doubly-periodic function which is analytic (except at poles), and which has no singularities other than poles in the finite part of the plane, is called an *elliptic function*.

A *cell* of an elliptic function, $f(z)$ is a parallelogram $z, z + 2\omega_1, z + 2\omega_1 + 2\omega_2, z + 2\omega_2$ for which none of the poles of $f(z)$ lie on the edges of the cell. If c is constant, then the number of roots of $f(z) = c$ that lie within a cell is the *order* of the elliptic function and is equal to the number of poles of $f(z)$ within the cell [32, Section 20.13].

Whittaker and Watson introduce the general properties of elliptic functions by considering the *Weierstrass* function:

$$\wp(z) = \frac{1}{z^2} + \sum_{\omega \in \mathbb{L} \setminus \{0\}} \left(\frac{1}{(z - \omega)^2} - \frac{1}{\omega^2} \right)$$

where the set of points $\omega = 2m\omega_1 + 2n\omega_2$ with $m, n \in \mathbb{Z}$, constitutes a *lattice*, \mathbb{L} . *Whittaker and Watson* [32, Section 20.51] show that “any elliptic function can be expressed in terms of the Weierstrassian elliptic functions $\wp(z)$ and $\wp'(z)$ with the same periods, the expression being rational in $\wp(z)$ and linear in $\wp'(z)$ ”. $\wp'(z)$ represents the derivative of $\wp(z)$ with-respect-to z .

B.2 Legendre's elliptic integrals

$F(\phi, \kappa)$ is the *incomplete elliptic integral of the first kind* [36, Equation 19.2.4]

$$F(\phi, \kappa) = \int_0^\phi \frac{d\theta}{\sqrt{1 - \kappa^2 \sin^2 \theta}}$$

^aThe “NIST Digital Library of Mathematical Functions” is the successor to the “Handbook of Mathematical Functions” by *Abramowitz and Stegun* [86]. Unfortunately, pages are missing from scans of *Abramowitz and Stegun* available on the WWW.

$$= \int_0^{\sin \phi} \frac{dt}{\sqrt{1-t^2}\sqrt{1-\kappa^2 t^2}}$$

where κ is the *elliptic modulus*. $\kappa' = \sqrt{1-\kappa^2}$ is the *complementary elliptic modulus*.

$K(\kappa) = F\left(\frac{\pi}{2}, \kappa\right)$ is the *complete elliptic integral of the first kind* [36, Equation 19.2.8]. $K'(\kappa) = K(\kappa')$.

$E(\phi, \kappa)$ is the *incomplete elliptic integral of the second kind* [36, Equation 19.2.5]:

$$\begin{aligned} E(\phi, \kappa) &= \int_0^\phi \sqrt{1-\kappa^2 \sin^2 \theta} d\theta \\ &= \int_0^{\sin \phi} \frac{\sqrt{1-\kappa^2 t^2}}{\sqrt{1-t^2}} dt \end{aligned}$$

$E(\kappa) = E\left(\frac{\pi}{2}, \kappa\right)$ is the *complete elliptic integral of the second kind*.

$\Pi(\phi, \eta, \kappa)$ is the *incomplete elliptic integral of the third kind* [36, Equation 19.2.7]:

$$\begin{aligned} \Pi(\phi, \eta, \kappa) &= \int_0^\phi \frac{d\theta}{\sqrt{1-\kappa^2 \sin^2 \theta}(1-\eta \sin^2 \theta)} \\ &= \int_0^{\sin \phi} \frac{dt}{\sqrt{1-t^2}\sqrt{1-\kappa^2 t^2}(1-\eta t^2)} \end{aligned}$$

$Pi(\eta, \kappa) = \Pi\left(\frac{\pi}{2}, \eta, \kappa\right)$ is the *complete elliptic integral of the third kind*.

B.3 Computation of Legendre's elliptic integrals

Carlson [14] and [36, Section 19.15] describes a method of computing Legendre's elliptic integrals. He defines the functions:

$$\begin{aligned} R_F(x, y, z) &= \frac{1}{2} \int_0^\infty [(t+x)(t+y)(t+z)]^{-\frac{1}{2}} dt \\ R_C(x, y) &= R_F(x, y, y) \\ R_J(x, y, z, \rho) &= \frac{3}{2} \int_0^\infty [(t+x)(t+y)(t+z)]^{-\frac{1}{2}} (t+\rho)^{-1} dt \\ R_D(x, y, z) &= R_J(x, y, z, z) \end{aligned}$$

and states that [14, Section 4]:

$$\begin{aligned} F(\phi, \kappa) &= (\sin \phi) R_F(\cos^2 \phi, 1 - \kappa^2 \sin^2 \phi, 1) \\ E(\phi, \kappa) &= (\sin \phi) R_F(\cos^2 \phi, 1 - \kappa^2 \sin^2 \phi, 1) - \frac{1}{3} \kappa^2 (\sin \phi)^3 R_D(\cos^2 \phi, 1 - \kappa^2 \sin^2 \phi, 1) \\ \Pi(\phi, \eta, \kappa) &= \sin(\phi) R_F(\cos^2 \phi, 1 - \kappa^2 \sin^2 \phi, 1) + \frac{\eta}{3} R_J(\cos^2 \phi, 1 - \kappa^2 \sin^2 \phi, 1, 1 - \eta \sin^2 \phi) \end{aligned}$$

Note that for $\Pi(\phi, \eta, \kappa)$ the sign of the terms in η is the reverse of that shown by Carlson [14, Equation 4.3].

The complete elliptic integrals are:

$$\begin{aligned} K(\kappa) &= R_F(0, 1 - \kappa^2, 1) \\ E(\kappa) &= R_F(0, 1 - \kappa^2, 1) - \frac{1}{3} \kappa^2 R_D(0, 1 - \kappa^2, 1) \\ Pi(\eta, \kappa) &= R_F(0, 1 - \kappa^2, 1) + \frac{\eta}{3} \kappa^2 R_J(0, 1 - \kappa^2, 1, 1 - \eta) \end{aligned}$$

The computation of R_F uses the, so-called, *duplication formula* [36, Equation 19.26.18]:

$$R_F(x, y, z) = R_F\left(\frac{x+\lambda}{4}, \frac{y+\lambda}{4}, \frac{z+\lambda}{4}\right)$$

where $\lambda = \sqrt{xy} + \sqrt{yz} + \sqrt{zx}$.

Algorithm B.1 [14, Algorithm 1] computes Carlson's R_F function, Algorithm B.2 [14, Algorithm 2] computes Carlson's R_C function, Algorithm B.3 [14, Algorithm 3] computes Carlson's R_J function, and Algorithm B.4 [14, Algorithm 4] computes Carlson's R_D function.

B.4 Jacobi's theta functions

Jacobi's elliptic functions can be defined as ratios of Jacobi's *theta* functions [36, Section 20.2]. These are defined by the Fourier series:

$$\begin{aligned} \theta_1(z, q) &= 2 \sum_{n=0}^{\infty} (-1)^n q^{(n+\frac{1}{2})^2} \sin((2n+1)z) \\ \theta_2(z, q) &= 2 \sum_{n=0}^{\infty} q^{(n+\frac{1}{2})^2} \cos((2n+1)z) \\ \theta_3(z, q) &= 1 + 2 \sum_{n=1}^{\infty} q^{n^2} \cos(2nz) \\ \theta_4(z, q) &= 1 + 2 \sum_{n=1}^{\infty} (-1)^n q^{n^2} \cos(2nz) \end{aligned}$$

where $q = e^{i\pi\tau}$ is called the *nome*, with $\Im\tau > 0$ so that $0 < |q| < 1$. For most applications, the unit cell is a rectangle so that $\Re\tau = 0$ and $0 < q < 1$.

Jacobi's *Eta* and *Theta* functions [36, Section 20.1] are, respectively:

$$\begin{aligned} H(z, q) &= \theta_1 \left(\frac{z}{\theta_3^2(0, q)}, q \right) \\ \Theta(z, q) &= \theta_4 \left(\frac{z}{\theta_3^2(0, q)}, q \right) \end{aligned}$$

B.5 Computation of Jacobi's theta functions

The Fourier series of Jacobi's theta functions usually converge rapidly because of the doubly-exponential factors q^{n^2} . The following transformations^b are used to compute Jacobi's theta functions when $|q|$ is close to 1 with $\tau' = -\frac{1}{\tau}$ [36, Section

^bSee [36, Section 23.15(i)]. Suppose \mathcal{A} denotes a bilinear transformation on τ :

$$\mathcal{A}\tau = \frac{a\tau + b}{c\tau + d}$$

where a, b, c and d are integers and $ad - bc = 1$. A *modular function* $f(\tau)$ is a function of τ that is meromorphic in the half-plane $\Im\tau > 0$, and has the property that for all \mathcal{A} :

$$f(\mathcal{A}\tau) = c_{\mathcal{A}} (c\tau + d)^l f(\tau)$$

20.7(viii)]:

$$\begin{aligned}(-\imath\tau)^{\frac{1}{2}}\theta_1(z,\tau) &= -\imath \exp\left(\frac{\imath\tau'z^2}{\pi}\right)\theta_1(z\tau',\tau') \\(-\imath\tau)^{\frac{1}{2}}\theta_2(z,\tau) &= \exp\left(\frac{\imath\tau'z^2}{\pi}\right)\theta_4(z\tau',\tau') \\(-\imath\tau)^{\frac{1}{2}}\theta_3(z,\tau) &= \exp\left(\frac{\imath\tau'z^2}{\pi}\right)\theta_3(z\tau',\tau') \\(-\imath\tau)^{\frac{1}{2}}\theta_4(z,\tau) &= \exp\left(\frac{\imath\tau'z^2}{\pi}\right)\theta_2(z\tau',\tau')\end{aligned}$$

B.6 Jacobi's elliptic functions

See [36, Section 22.2]. The nome, q , is, in terms of the modulus, κ :

$$q = e^{-\pi \frac{K'(\kappa)}{K(\kappa)}}$$

The elliptic modulus, κ , is, in terms of the nome, q :

$$\begin{aligned}\kappa &= \frac{\theta_2^2(0,q)}{\theta_3^2(0,q)} \\ \kappa' &= \frac{\theta_4^2(0,q)}{\theta_3^2(0,q)} \\ K(\kappa) &= \frac{\pi}{2}\theta_3^2(0,q)\end{aligned}$$

If $\zeta = \frac{\pi z}{2K(\kappa)}$, then:

$$\begin{aligned}\text{sn}(z,\kappa) &= \frac{\theta_3(0,q)}{\theta_2(0,q)} \frac{\theta_1(\zeta,q)}{\theta_4(\zeta,q)} = \frac{1}{\text{ns}(z,\kappa)} \\\text{cn}(z,\kappa) &= \frac{\theta_4(0,q)}{\theta_2(0,q)} \frac{\theta_2(\zeta,q)}{\theta_4(\zeta,q)} = \frac{1}{\text{nc}(z,\kappa)} \\\text{dn}(z,\kappa) &= \frac{\theta_4(0,q)}{\theta_3(0,q)} \frac{\theta_3(\zeta,q)}{\theta_4(\zeta,q)} = \frac{1}{\text{nd}(z,\kappa)} \\\text{sd}(z,\kappa) &= \frac{\theta_3^2(0,q)}{\theta_2(0,q)\theta_4(0,q)} \frac{\theta_1(\zeta,q)}{\theta_3(\zeta,q)} = \frac{1}{\text{ds}(z,\kappa)} \\\text{cd}(z,\kappa) &= \frac{\theta_3(0,q)}{\theta_2(0,q)} \frac{\theta_2(\zeta,q)}{\theta_3(\zeta,q)} = \frac{1}{\text{dc}(z,\kappa)} \\\text{sc}(z,\kappa) &= \frac{\theta_3(0,q)}{\theta_4(0,q)} \frac{\theta_1(\zeta,q)}{\theta_2(\zeta,q)} = \frac{1}{\text{cs}(z,\kappa)}\end{aligned}$$

From [36, Section 22.2]:

As a function of z with fixed κ , each of the 12 Jacobian elliptic functions is doubly periodic, having two periods whose ratio is not real. Each is meromorphic^c in z for fixed κ , with simple poles and zeros, and each is meromorphic in κ for fixed z . For $k \in [0, 1]$, all functions are real for $z \in \mathbb{R}$.

The Jacobian elliptic functions have order 2; there are two simple poles in each cell. Table B.1 [36, Tables 22.4.1 and 22.4.2] summarises the periods, pole locations and zero locations of the Jacobian elliptic functions.

Glaisher's notation for the Jacobian elliptic functions is [36, Equation 22.2.10]:

$$pq(z,\kappa) = \frac{pr(z,\kappa)}{qr(z,\kappa)} = \frac{1}{qp(z,\kappa)}$$

where p, q and r are any three of the letters s, c, d and n . Figure B.1 [36, Figure 22.4.2] shows a mnemonic for the nomenclature of the Jacobian elliptic functions. If p and q are any two distinct letters from the set s, c, d and n which appear in counter-clockwise orientation at all corners of all lattice unit cells. Then:

where $c_{\mathcal{A}}$ is a constant depending on \mathcal{A} , and l , called the level, is an integer or half an odd integer. If, as a function of q , $f(\tau)$ is analytic at $q = 0$, then $f(\tau)$ is called a *modular form*.

^cSee Appendix A.10.

Periods	z-poles				z-zeros			
	$\imath K'$	$K + \imath K'$	K	0	0	K	$K + \imath K'$	$\imath K'$
$4K, 2\imath K'$	sn	cd	dc	ns	sn	cd	dc	ns
$4K, 2K + 2\imath K'$	cn	sd	nc	ds	sd	cn	ds	nc
$2K, 4\imath K'$	dn	nd	sc	cs	sc	cs	dn	nd

Table B.1: Periods, pole locations and zero locations of the Jacobian elliptic functions

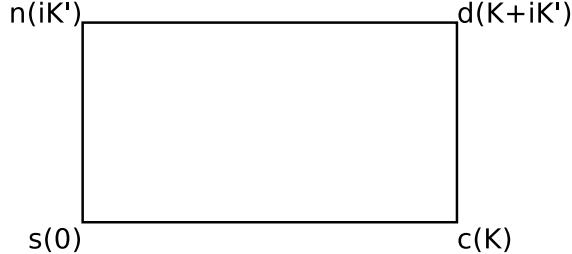

Figure B.1: Jacobian elliptic filter z-plane unit cell

- in any lattice unit cell $pq(z, \kappa)$ has a simple zero at $z = p$ and a simple pole at $z = q$
- the difference between p and the nearest q is a half-period of $pq(z, \kappa)$

The half-period will be plus or minus a member of the triple $K, \imath K', K + \imath K'$; the other two members of this triple are quarter-periods of $pq(z, \kappa)$.

B.7 Inverses of Jacobi's elliptic functions

The inverses of Jacobi's sn, cn and cd elliptic functions are, respectively [36, Section 22.15(ii)]:

$$\begin{aligned} \text{arcsn}(x, \kappa) &= \int_0^x \frac{dt}{\sqrt{(1-t^2)(1-\kappa^2 t^2)}}, \quad -1 \leq x \leq 1 \\ \text{arccn}(x, \kappa) &= \int_x^1 \frac{dt}{\sqrt{(1-t^2)(\kappa'^2 + \kappa^2 t^2)}}, \quad -1 \leq x \leq 1 \\ \text{arcdn}(x, \kappa) &= \int_x^1 \frac{dt}{\sqrt{(1-t^2)(\kappa'^2 + \kappa^2 t^2)}}, \quad -1 \leq x \leq 1 \\ \text{arcdn}(x, \kappa) &= \int_x^1 \frac{dt}{\sqrt{(1-t^2)(t^2 - \kappa'^2)}}, \quad \kappa' \leq x \leq 1 \\ \text{arccd}(x, \kappa) &= \int_x^1 \frac{dt}{\sqrt{(1-t^2)(1-\kappa^2 t^2)}}, \quad -1 \leq x \leq 1 \end{aligned}$$

Carlson [15, Section 2.1] shows how to calculate the inverse Jacobian elliptic functions with the R_F function. For example,

$$\text{arcsn}(z, \kappa) = z R_F(1, 1-z^2, 1-\kappa^2 z^2)$$

B.8 Elementary identities for the elliptic integrals and elliptic functions

Note that $\text{arcsn}(x, \kappa) = F(\arcsin x, \kappa)$ so that:

$$x = \int_0^{\text{sn}(x, \kappa)} \frac{dt}{\sqrt{(1-t^2)(1-\kappa^2 t^2)}}, \quad -1 \leq x \leq 1, \quad 0 \leq \kappa \leq 1$$

The identities:

$$\text{sn}(x, \kappa) = \sin \phi$$

$$\begin{aligned}\operatorname{cn}(x, \kappa) &= \cos \phi \\ \operatorname{dn}(x, \kappa) &= \sqrt{1 - \kappa^2 \operatorname{sn}^2(x, \kappa)}\end{aligned}$$

give (omitting the x and κ arguments):

$$\begin{aligned}\operatorname{sn}^2 + \operatorname{cn}^2 &= 1 \\ \operatorname{dn}^2 &= 1 - \kappa^2 \operatorname{sn}^2 = \kappa'^2 + \kappa^2 \operatorname{cn}^2 = \operatorname{cn}^2 + \kappa'^2 \operatorname{sn}^2\end{aligned}$$

The identities:

$$\begin{aligned}\operatorname{sn}(x, \kappa) &= \sin \phi \\ \operatorname{cn}(x, \kappa) &= \cos \phi \\ \operatorname{dn}(x, \kappa) &= \sqrt{1 - \kappa^2 \operatorname{sn}^2(x, \kappa)}\end{aligned}$$

give (omitting the x and κ arguments):

$$\begin{aligned}\operatorname{sn}^2 + \operatorname{cn}^2 &= 1 \\ \operatorname{dn}^2 &= 1 - \kappa^2 \operatorname{sn}^2 = \kappa'^2 + \kappa^2 \operatorname{cn}^2 = \operatorname{cn}^2 + \kappa'^2 \operatorname{sn}^2\end{aligned}$$

The half-argument identities for the sn and cn functions are [36, Equations 22.6.19 and 22.6.20]:

$$\begin{aligned}\operatorname{sn}^2\left(\frac{z}{2}, \kappa\right) &= \frac{1 - \operatorname{cn}(z, \kappa)}{1 + \operatorname{dn}(z, \kappa)} \\ \operatorname{cn}^2\left(\frac{z}{2}, \kappa\right) &= \frac{-\kappa'^2 + \operatorname{dn}(z, \kappa) + \kappa^2 \operatorname{cn}(z, \kappa)}{\kappa^2 (1 + \operatorname{cn}(z, \kappa))}\end{aligned}$$

For many more such identities, see, for example, the DLMF [36, Section 22.6].

B.9 Related functions

Jacobi's *amplitude* function [36, Equation 22.16.1] is:

$$\operatorname{am}(x, \kappa) = \arcsin(\operatorname{sn}(x, \kappa))$$

If $-K \leq x \leq K$ then the following four equations are equivalent [36, Equations 22.16.10 to 22.16.13]:

$$\begin{aligned}x &= F(\phi, \kappa) \\ \operatorname{am}(x, \kappa) &= \phi \\ \operatorname{sn}(x, \kappa) &= \sin \phi = \sin(\operatorname{am}(x, \kappa)) \\ \operatorname{cn}(x, \kappa) &= \cos \phi = \cos(\operatorname{am}(x, \kappa))\end{aligned}$$

Jacobi's *Epsilon* function [36, Equations 22.16.14 and 22.16.31] is, for $-K \leq x \leq K$:

$$\begin{aligned}\mathcal{E}(x, \kappa) &= \int_0^{\operatorname{sn}(x, \kappa)} \sqrt{\frac{1 - \kappa^2 t^2}{1 - t^2}} dt \\ &= E(\operatorname{am}(x, \kappa), \kappa)\end{aligned}$$

where $-K < x < K$.

Jacobi's *Zeta* function [36, Equation 22.16.32] is:

$$Z(x, \kappa) = E(\arcsin(\operatorname{sn}(x, \kappa)), \kappa) - \frac{E(\kappa)}{K(\kappa)} x$$

Alternatively [36, Equation 22.16.30]:

$$Z(z, \kappa) = \frac{1}{\Theta(z, \kappa)} \frac{d\Theta(z, \kappa)}{dz} = \frac{1}{\theta_3^2(0, q) \theta_4(\xi, q)} \frac{d\theta_4(\xi, q)}{d\xi}$$

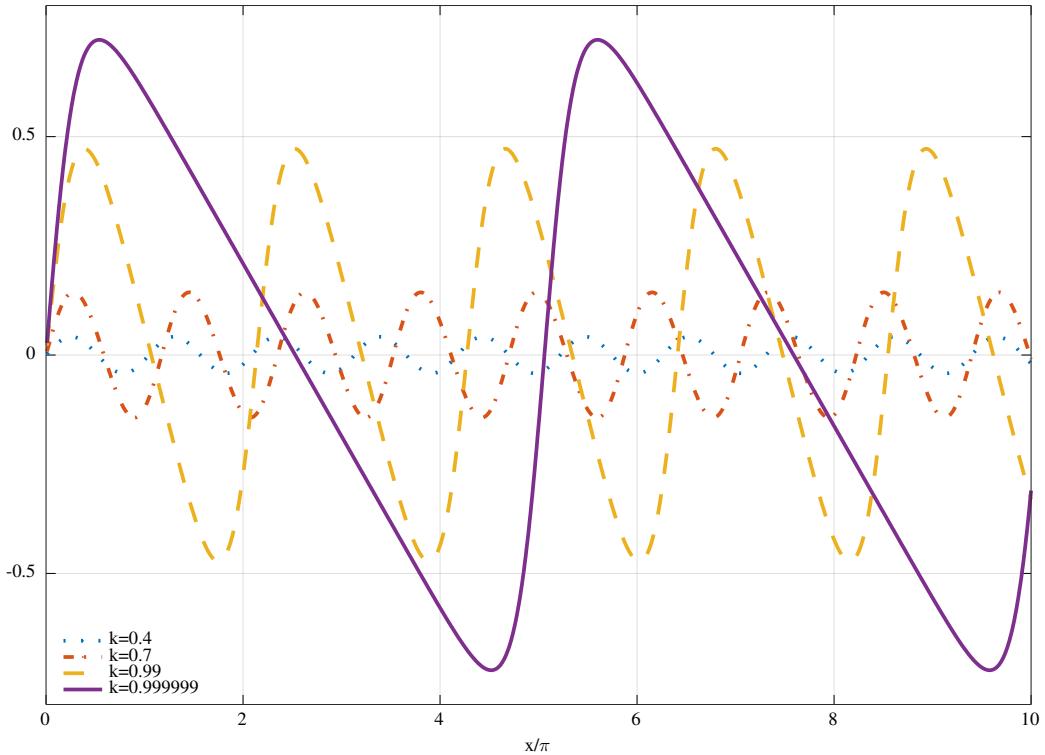

Figure B.2: Jacobi's Zeta function as shown in Figure 22.16.3 of the NIST Digital Library of Mathematical Functions [36]

where $\xi = \frac{z}{\theta_3^2(0,q)}$ and q is the *nome* corresponding to κ .

The *Zeta* function is periodic in $2K$ [36, 22.16.34]:

$$Z(x + 2K, \kappa) = Z(x, \kappa)$$

Also [36, 22.16.33]:

$$Z(x + K, \kappa) = Z(x, \kappa) - \kappa^2 \operatorname{sn}(x, \kappa) \operatorname{cd}(x, \kappa)$$

The *Boost C++ library* [20] and *Mathematica* [165] implementations of Jacobi's *Zeta* function use:

$$Z(\phi, \kappa) = E(\phi, \kappa) - \frac{E(\kappa)}{K(\kappa)} F(\phi, \kappa)$$

This definition obscures the periodicity in K . Figure 22.16.3 of the DLMF [36], shows the values of Jacobi's *Zeta* function for several elliptic moduluses, κ . Confusingly, this figure expresses the x argument as a multiple of π . The Octave script *jacobi_Zeta_test.m* reproduces Figure 22.16.3, as shown in Figure B.2.

B.10 Octave implementations

Table B.2 lists the Octave functions that implement the elliptic functions and integrals referred to in this Appendix. *ellipj* and *ellipke* are Octave built-in functions.

Function	Octave implementation
$\text{sn}(z, \kappa), \text{cn}(z, \kappa), \text{dn}(z, \kappa)$	<i>ellipj</i>
$K(\kappa), E(\kappa)$	<i>ellipke</i>
$\text{arcsn}(z, \kappa)$	<i>arcsn</i>
$\text{arcsc}(z, \kappa)$	<i>arcsc</i>

Appendix C

Review of *Lanczos* tridiagonalisation of an unsymmetric matrix

See *Golub and Van Loan* [38, Section 9.4.3]. The *Lanczos* tridiagonalisation calculates an orthogonal similarity transform, T , that reduces a matrix $A \in \mathbb{R}^{N \times N}$ to tridiagonal form, \mathcal{A} :

$$T^{-1}AT = \mathcal{A} = \begin{bmatrix} \alpha_0 & \beta_1 & 0 & 0 & \cdots & 0 \\ \gamma_1 & \alpha_1 & \beta_2 & 0 & \cdots & 0 \\ 0 & \gamma_2 & \alpha_2 & \beta_3 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \gamma_{N-2} & \alpha_{N-2} & \beta_{N-1} \\ 0 & 0 & \cdots & 0 & \gamma_{N-1} & \alpha_{N-1} \end{bmatrix}$$

The *Lanczos* tridiagonalisation calculates the column partitionings:

$$\begin{aligned} T &= [t_1 \ \cdots \ t_N] \\ T^{-T} &= P = [p_1 \ \cdots \ p_N] \end{aligned}$$

Comparing columns in $AT = T\mathcal{A}$ and $A^T P = P\mathcal{A}^T$, for $k \in [1, N - 1]$:

$$\begin{aligned} At_k &= \beta_{k-1}t_{k-1} + \alpha_{k-1}t_k + \gamma_k t_{k+1} && \text{with } \beta_0 t_0 \equiv 0 \\ A^T p_k &= \gamma_{k-1}p_{k-1} + \alpha_{k-1}p_k + \beta_k p_{k+1} && \text{with } \gamma_0 p_0 \equiv 0 \end{aligned}$$

In addition, since T is orthogonal and $P^T T = I_{N \times N}$:

$$\begin{aligned} \alpha_{k-1} &= p_k^T At_k \\ \beta_k p_{k+1} &\equiv r_k = (A - \alpha_{k-1}I)^T p_k - \gamma_{k-1}p_{k-1} \\ \gamma_k t_{k+1} &\equiv s_k = (A - \alpha_{k-1}I) t_k - \beta_{k-1}t_{k-1} \end{aligned}$$

Note that:

$$1 = p_{k+1}^T t_{k+1} = \left(\frac{r_k}{\beta_k} \right)^T \left(\frac{s_k}{\gamma_k} \right) \quad (\text{C.1})$$

and so if γ_k is specified in advance:

$$\beta_k = \frac{r_k^T s_k}{\gamma_k} \quad (\text{C.2})$$

A common choice is $\gamma_k = \|s_k\|_2$ ^a. Algorithm C.1 calculates the *Lanczos tridiagonalisation* of an unsymmetric matrix.

^aRecall that $\|s_k\|_2 = (s_k^T s_k)^{\frac{1}{2}}$.

Algorithm C.1 Lanczos tridiagonalisation of an unsymmetric matrix

Convert the matrix A to *tri-diagonal* form:

r_0 and s_0 are given unit 2-norm vectors with $r_0^T s_0 \neq 0$

$t_0 = 0$

$p_0 = 0$.

$k = 0$

while $r_k \neq 0 \wedge s_k \neq 0 \wedge r_k^T s_k \neq 0$ **do**

$$\gamma_k = \|s_k\|_2$$

$$\beta_k = \frac{r_k^T s_k}{\gamma_k}$$

$$t_{k+1} = \frac{\gamma_k}{\beta_k}$$

$$p_{k+1} = \frac{\gamma_k}{\beta_k}$$

$$k = k + 1$$

$$\alpha_{k-1} = p_k^T A t_k$$

$$r_k = (A - \alpha_{k-1} I)^T p_k - \gamma_{k-1} p_{k-1}$$

$$s_k = (A - \alpha_{k-1} I) t_k - \beta_{k-1} t_{k-1}$$

end while

If

$$\mathcal{A}_k = \begin{bmatrix} \alpha_0 & \beta_1 & 0 & 0 & \cdots & 0 \\ \gamma_1 & \alpha_1 & \beta_2 & 0 & \cdots & 0 \\ 0 & \gamma_2 & \alpha_2 & \beta_3 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \gamma_{k-2} & \alpha_{k-2} & \beta_{k-1} \\ 0 & 0 & \cdots & 0 & \gamma_{k-1} & \alpha_{k-1} \end{bmatrix}$$

then, when the loop of Algorithm C.1 terminates:

$$A^T \begin{bmatrix} p_1 & \cdots & p_k \end{bmatrix} = \begin{bmatrix} p_1 & \cdots & p_k \end{bmatrix} \mathcal{A}_k^T + r_k e_k^T$$

$$A \begin{bmatrix} t_1 & \cdots & t_k \end{bmatrix} = \begin{bmatrix} t_1 & \cdots & t_k \end{bmatrix} \mathcal{A}_k + s_k e_k^T$$

If $r_k = 0$ when the iteration terminates then $\text{span} \{ p_1 \dots p_k \}$ is a subspace for A . If $s_k = 0$ when the iteration terminates then $\text{span} \{ t_1 \dots t_k \}$ is a subspace for A . If neither of these conditions is true and $r_k^T s_k = 0$, then the tridiagonalisation process has failed. *Golub and Van Loan* [38, Section 9.4.4] give a brief review of the *Look-Ahead* technique for solving this problem. The Octave function *lanczos_tridiag* implements Algorithm C.1.

Appendix D

Review of Lagrange Interpolation

This chapter follows the review article of *Berrut* and *Trefethen* [64].

D.1 The barycentric Lagrange polynomial

Let $n + 1$ distinct interpolation points or *nodes*, x_j , be given, together with corresponding values, f_j . The interpolation problem is to find a polynomial such that $p(x_j) = f_j$. The *Lagrange* solution is:

$$p(x) = \sum_{j=0}^n f_j l_j(x)$$

$$l_j = \frac{\prod_{k=0, k \neq j}^n (x - x_k)}{\prod_{k=0, k \neq j}^n (x_j - x_k)} \quad (\text{D.1})$$

The *Lagrange polynomial* l_j corresponding to x_j has the property:

$$l_j(x_k) = \begin{cases} 1, & j = k \\ 0, & \text{otherwise} \end{cases}$$

If $l(x) = (x - x_0) \dots (x - x_n)$, and the *barycentric weights* are defined as:

$$w_j = \frac{1}{\prod_{k \neq j} (x_j - x_k)} = \frac{1}{l'(x_j)} \quad (\text{D.2})$$

then l_j can be rewritten as:

$$l_j = l(x) \frac{w_j}{(x - x_j)} \quad (\text{D.3})$$

so that:

$$p(x) = l(x) \sum_{j=0}^n \frac{w_j}{x - x_j} f_j \quad (\text{D.4})$$

If all $f_j = 1$,

$$1 = \sum_{j=0}^n l_j(x) = l(x) \sum_{j=0}^n \frac{w_j}{x - x_j}$$

giving the *barycentric formula* for $p(x)$:

$$p(x) = \frac{\sum_{j=0}^n \frac{w_j}{x - x_j} f_j}{\sum_{j=0}^n \frac{w_j}{x - x_j}} \quad (\text{D.5})$$

D.2 Node distributions

Explicit formulas for the weights, w_j , are available for certain sets of nodes, x_j . If the nodes are equidistant, with spacing $h = \frac{2}{n}$, in the interval $[-1, 1]$, then:

$$w_j = \frac{(-1)^{n-j} \binom{n}{j}}{h^n n!}$$

After cancelling factors independent of j :

$$w_j = (-1)^j \binom{n}{j}$$

Clearly, for large n , the weights vary by exponentially large factors and, consequently, interpolation in equally spaced points is *ill-conditioned*^a. Unless n is small, it is better to use node distributions that are clustered at the end-points of the interval. The simplest such distributions are the *Chebyshev nodes*, formed by projecting equally spaced points on the unit circle down to the interval $[-1, 1]$. The *Chebyshev nodes of the first kind* are:

$$x_j = \cos \frac{(2j+1)\pi}{2n+2}$$

with weights:

$$w_j = (-1)^j \sin \frac{(2j+1)\pi}{2n+2}$$

The *Chebyshev nodes of the second kind* are:

$$x_j = \cos \frac{j\pi}{n}$$

with weights:

$$\begin{aligned} w_j &= (-1)^j \delta_j \\ \delta_j &= \begin{cases} \frac{1}{2}, & j = 0 \text{ or } j = n \\ 1, & \text{otherwise} \end{cases} \end{aligned}$$

Higham [101] has shown that Equation D.4 is unconditionally numerically stable and that Equation D.5 is stable if the interpolation points are clustered appropriately.

The Octave script *lagrange_interp_test.m* exercises the implementation of Lagrange interpolation in the Octave function *lagrange_interp*^b. Figure D.1 attempts to reproduce *Berrut* and *Trefethen*'s Figure 5.1 for 21 Chebyshev nodes of the second kind. Figure D.2 repeats the interpolation experiment with linearly spaced nodes.

^aThis is called the *Runge phenomenon*

^bThe interpolation is much more accurate if the function calculates the weights by the product in Equation D.2 rather than Equation D.3

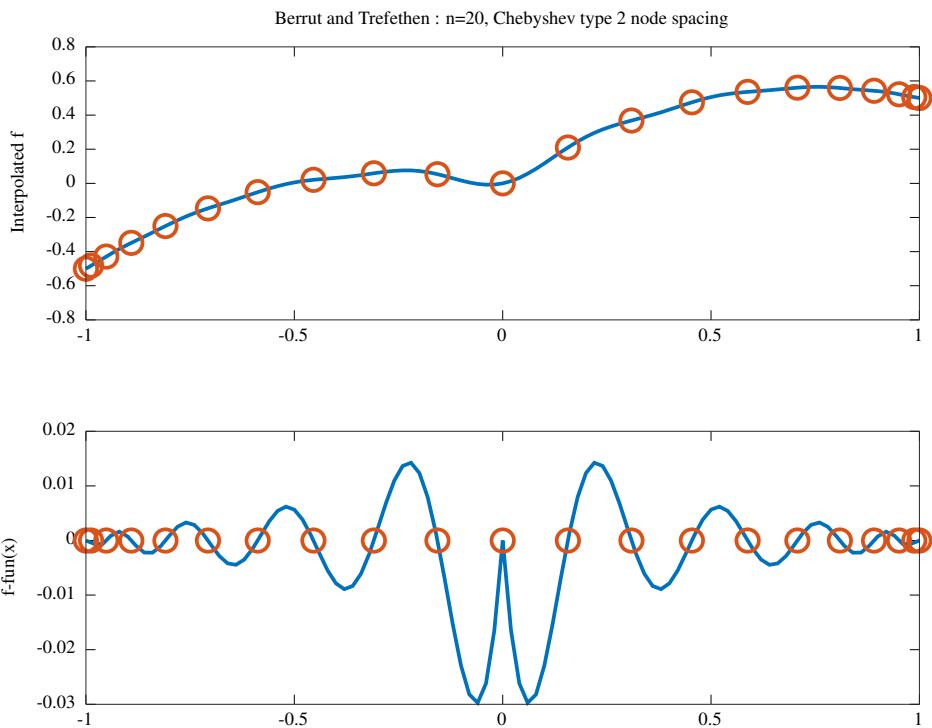

Figure D.1: Lagrange interpolation of the function $\text{fun}(x) = |x| + \frac{x}{2} - x^2$ with 21 Chebyshev nodes of the second kind and 101 interpolated values on $[-1, 1]$. The marks indicate the values, f_k , being interpolated.

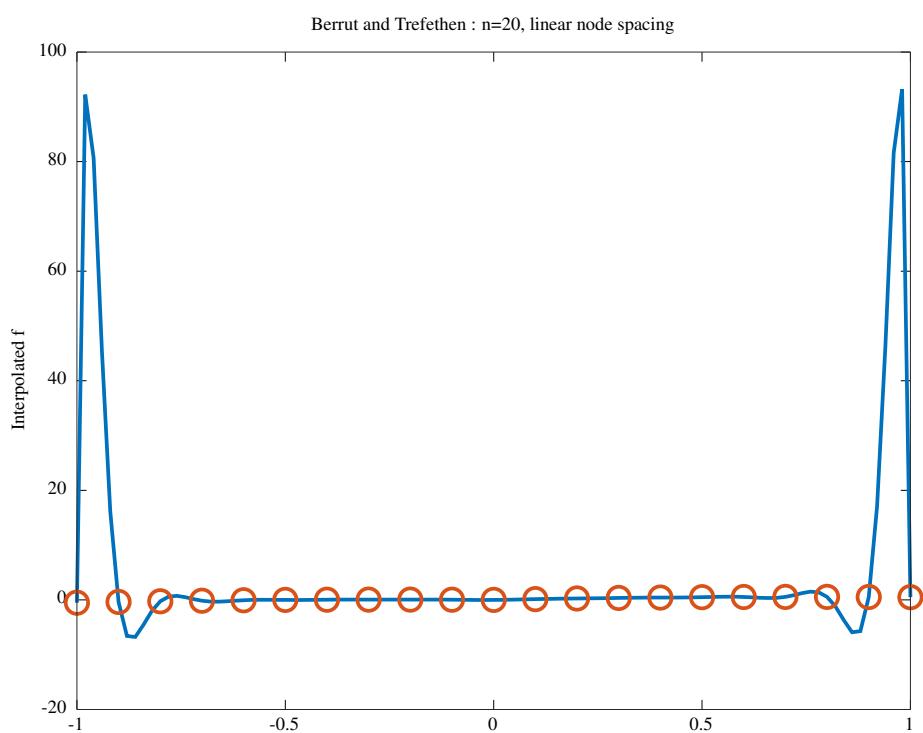

Figure D.2: Lagrange interpolation of the function $\text{fun}(x) = |x| + \frac{x}{2} - x^2$ with 21 linearly spaced nodes and 101 interpolated values on $[-1, 1]$. The marks indicate the values, f_k , being interpolated.

Appendix E

IIR filter amplitude, phase and group-delay frequency responses

This section describes the derivation of the amplitude (magnitude) and group delay responses and their first and second partial derivatives (gradient vector and Hessian matrix) with respect to the pole and zero locations of the transfer function. Some possibilities for constructing the first and second partial derivatives are:

- numerical differentiation by evaluation of the function at a perturbed input coefficient vector
- symbolic differentiation by a symbolic algebra package. For example, *Maxima* [164] or the *OctaveForge* symbolic calculation toolbox [105]
- differentiation by hand
- so-called *automatic differentiation*: “a technology for automatically augmenting computer programs, including arbitrarily complex simulations, with statements for the computation of derivatives”. See [13, *tools*].

Below I use a mixture of differentiation by hand and symbolic differentiation to derive the formulas implemented in Octave code and use numerical differentiation to test the formulas^a.

Richards [85] shows expressions for the magnitude and group-delay of an IIR filter with an integer decimation factor, R , and transfer function

$$H(z) = \frac{N(z)}{D(z)} = K \frac{\sum_{j=0}^J n_j z^{-j}}{1 + \sum_{l=1}^L d_l z^{-Rl}} \quad (\text{E.1})$$

The polar coordinates of the zeros of $H(z)$ are assumed to be $\{z_{0j}\} = \{(R_{0j}, 0), (r_{0j}, \pm\theta_{0j})\}$. Similarly, the poles of $H(z)$ are assumed to be $\{v_{pk}\} = \{(R_{pk}, 0), (r_{pk}, \pm\theta_{pk})\}$ where $v = z^R$ (so that each pole on the v plane corresponds to R equally spaced poles on the z plane). All coefficients are allowed to be negative so that the responses are differentiable with respect to the coefficients. This means that the amplitude response derived below can be negative if the gain coefficient is negative and, consequently, the phase of the gain coefficient is not included in the phase response listed below. If $R \geq 2$, the gradients of the amplitude response are undefined for real and complex poles with radius 0.

For convenience in the following, rewrite Equation E.1 as:

$$H(z) = K \frac{z^{-J}}{z^{-RL}} \frac{\sum_{j=0}^J n_j z^{J-j}}{\left[z^{RL} + \sum_{l=1}^L d_l z^{R(L-l)}\right]}$$

Suppose there is a zero at $v = re^{i\theta}$, then the magnitude response due to this zero is

$$\begin{aligned} |(e^{i\omega} - re^{i\theta})| &= |(\cos \omega - r \cos \theta) + i(\sin \omega - r \sin \theta)| \\ &= \{\cos^2 \omega - 2r \cos \omega \cos \theta + r^2 \cos^2 \theta + \sin^2 \omega - 2r \sin \omega \sin \theta + r^2 \sin^2 \theta\}^{\frac{1}{2}} \end{aligned}$$

^aIn the examples above, the Hessian of the phase response is calculated numerically and that matrix initialises the diagonal of the BFGS positive-definite approximation to the Hessian.

$$= \{1 - 2r \cos(\omega - \theta) + r^2\}^{\frac{1}{2}}$$

and the phase due to this zero is

$$\arg\{e^{i\omega} - re^{i\theta}\} = \arctan\left\{\frac{\sin\omega - r\sin\theta}{\cos\omega - r\cos\theta}\right\}$$

so that the group delay due to this zero is

$$\begin{aligned} -\frac{d}{d\omega} \arg\{e^{i\omega} - re^{i\theta}\} &= -\left[1 + \left(\frac{\sin\omega - r\sin\theta}{\cos\omega - r\cos\theta}\right)^2\right]^{-1} \left[\frac{(\cos\omega - r\cos\theta)\cos\omega + (\sin\omega - r\sin\theta)\sin\omega}{(\cos\omega - r\cos\theta)^2}\right] \\ &= -\frac{1 - r\cos\theta\cos\omega - r\sin\theta\sin\omega}{(\cos\omega - r\cos\theta)^2 + (\sin\omega - r\sin\theta)^2} \\ &= -\frac{1 - r\cos(\omega - \theta)}{1 - 2r\cos(\omega - \theta) + r^2} \end{aligned}$$

Using these results, for decimation factor R , $s = \frac{1}{R}$, U real zeros, V real poles, $\frac{M}{2}$ conjugate zero pairs and $\frac{Q}{2}$ conjugate pole pairs, the magnitude response of $H(z)$ is

$$\begin{aligned} A(\omega) &= K \times \frac{\prod_{j=1}^U \{1 - 2R_{0j}\cos\omega + R_{0j}^2\}^{\frac{1}{2}}}{\prod_{j=1}^V \prod_{i=0}^{R-1} \{1 - 2R_{pj}^s \cos(\omega - s2\pi i) + R_{pj}^{2s}\}^{\frac{1}{2}}} \times \dots \\ &\quad \dots \frac{\prod_{j=1}^{\frac{M}{2}} \{1 - 2r_{0j}\cos(\omega - \theta_{0j}) + r_{0j}^2\}^{\frac{1}{2}}}{\prod_{j=1}^{\frac{Q}{2}} \prod_{i=0}^{R-1} \{1 - 2r_{pj}^s \cos(\omega - s(\theta_{pj} + 2\pi i)) + r_{pj}^{2s}\}^{\frac{1}{2}}} \times \dots \\ &\quad \dots \frac{\prod_{j=1}^{\frac{M}{2}} \{1 - 2r_{0j}\cos(\omega + \theta_{0j}) + r_{0j}^2\}^{\frac{1}{2}}}{\prod_{j=1}^{\frac{Q}{2}} \prod_{i=0}^{R-1} \{1 - 2r_{pj}^s \cos(\omega + s(\theta_{pj} + 2\pi i)) + r_{pj}^{2s}\}^{\frac{1}{2}}} \end{aligned}$$

the phase response of $H(z)$ is^b

$$\begin{aligned} P(\omega) &= [(V+Q)R - (U+M)]\omega + \dots \\ &\quad \dots \sum_{j=1}^U \arctan\left(\frac{\sin\omega}{\cos\omega - R_{0j}}\right) - \dots \\ &\quad \dots \sum_{j=1}^V \left\{ \sum_{i=0}^{R-1} \arctan\left(\frac{\sin\omega - R_{pj}^s \sin(s2\pi i)}{\cos\omega - R_{pj}^s \cos(s2\pi i)}\right) \right\} + \dots \\ &\quad \dots \sum_{j=1}^{\frac{M}{2}} \arctan\left(\frac{\sin 2\omega - 2r_{0j}\cos\theta_{0j}\sin\omega}{\cos 2\omega - 2r_{0j}\cos\theta_{0j}\cos\omega + r_{0j}^2}\right) - \dots \\ &\quad \dots \sum_{j=1}^{\frac{Q}{2}} \left\{ \sum_{i=0}^{R-1} \arctan\left(\frac{\sin 2\omega - 2r_{pj}^s \cos[s(\theta_{pj} + 2\pi i)]\sin\omega}{\cos 2\omega - 2r_{pj}^s \cos[s(\theta_{pj} + 2\pi i)]\cos\omega + r_{pj}^{2s}}\right) \right\} \end{aligned}$$

and the group-delay response of $H(z)$ is^c

$$\begin{aligned} T(\omega) &= -[(V+Q)R - (U+M)] - \dots \\ &\quad \dots \sum_{j=1}^U \frac{1 - R_{0j}\cos\omega}{1 - 2R_{0j}\cos\omega + R_{0j}^2} + \dots \end{aligned}$$

^bNote that $\arg\{K\}$ is not included here. The sign of K is included in the amplitude response. This means that the amplitude response returned may be negative. This is allowed so that $\frac{\partial A(\omega)}{\partial K}$ is well defined at $K = 0$.

^cAn alternative derivation of the group delay, $T(\omega)$, is:

$$\begin{aligned} H(e^{i\omega T}) &= A(\omega) e^{i\Theta(\omega)} \\ \ln H(e^{i\omega T}) &= \ln A(\omega) + i\Theta(\omega) \\ \frac{d}{d\omega} \left\{ \ln H(e^{i\omega T}) \right\} &= \frac{A'(\omega)}{A(\omega)} + i\Theta'(\omega) \\ T(\omega) &= -\frac{d}{d\omega} \Theta(\omega) = -\Im \left\{ \frac{H'(e^{i\omega T})}{H(e^{i\omega T})} \right\} \end{aligned}$$

$$\begin{aligned}
& \cdots \sum_{j=1}^V \left\{ \sum_{i=0}^{R-1} \frac{1 - R_{pj}^s \cos(\omega - s2\pi i)}{1 - 2R_{pj}^s \cos(\omega - s2\pi i) + R_{pj}^{2s}} \right\} - \cdots \\
& \cdots \sum_{j=1}^{\frac{M}{2}} \left\{ \frac{1 - r_{0j} \cos(\omega - \theta_{0j})}{1 - 2r_{0j} \cos(\omega - \theta_{0j}) + r_{0j}^2} + \frac{1 - r_{0j} \cos(\omega + \theta_{0j})}{1 - 2r_{0j} \cos(\omega + \theta_{0j}) + r_{0j}^2} \right\} + \cdots \\
& \cdots \sum_{j=1}^{\frac{Q}{2}} \left\{ \sum_{i=0}^{R-1} \frac{1 - r_{pj}^s \cos(\omega - s(\theta_{pj} + 2\pi i))}{1 - 2r_{pj}^s \cos(\omega - s(\theta_{pj} + 2\pi i)) + r_{pj}^{2s}} \right\} + \cdots \\
& \cdots \sum_{j=1}^{\frac{Q}{2}} \left\{ \sum_{i=0}^{R-1} \frac{1 - r_{pj}^s \cos(\omega + s(\theta_{pj} + 2\pi i))}{1 - 2r_{pj}^s \cos(\omega + s(\theta_{pj} + 2\pi i)) + r_{pj}^{2s}} \right\}
\end{aligned}$$

The partial derivatives of the magnitude response are

$$\begin{aligned}
\frac{\partial A(\omega)}{\partial K} &= \frac{A(\omega)}{K} \\
\frac{\partial A(\omega)}{\partial R_{0j}} &= A(\omega) \left\{ \frac{R_{0j} - \cos \omega}{1 - 2R_{0j} \cos \omega + R_{0j}^2} \right\} \\
\frac{\partial A(\omega)}{\partial R_{pj}} &= -sR_{pj}^{s-1} A(\omega) \left\{ \sum_{i=0}^{R-1} \frac{R_{pj}^s - \cos(\omega - s2\pi i)}{1 - 2R_{pj}^s \cos(\omega - s2\pi i) + R_{pj}^{2s}} \right\} \\
\frac{\partial A(\omega)}{\partial r_{0j}} &= A(\omega) \left\{ \frac{r_{0j} - \cos(\omega - \theta_{0j})}{1 - 2r_{0j} \cos(\omega - \theta_{0j}) + r_{0j}^2} + \frac{r_{0j} - \cos(\omega + \theta_{0j})}{1 - 2r_{0j} \cos(\omega + \theta_{0j}) + r_{0j}^2} \right\} \\
\frac{\partial A(\omega)}{\partial \theta_{0j}} &= A(\omega) \left\{ \frac{r_{0j} \sin(\omega + \theta_{0j})}{1 - 2r_{0j} \cos(\omega + \theta_{0j}) + r_{0j}^2} - \frac{r_{0j} \sin(\omega - \theta_{0j})}{1 - 2r_{0j} \cos(\omega - \theta_{0j}) + r_{0j}^2} \right\} \\
\frac{\partial A(\omega)}{\partial r_{pj}} &= -sr_{pj}^{s-1} A(\omega) \sum_{i=0}^{R-1} \left\{ \frac{r_{pj}^s - \cos(\omega - s(\theta_{pj} + 2\pi i))}{1 - 2r_{pj}^s \cos(\omega - s(\theta_{pj} + 2\pi i)) + r_{pj}^{2s}} + \cdots \right. \\
&\quad \left. \cdots \frac{r_{pj}^s - \cos(\omega + s(\theta_{pj} + 2\pi i))}{1 - 2r_{pj}^s \cos(\omega + s(\theta_{pj} + 2\pi i)) + r_{pj}^{2s}} \right\} \\
\frac{\partial A(\omega)}{\partial \theta_{pj}} &= -sr_{pj}^s A(\omega) \sum_{i=0}^{R-1} \left\{ \frac{\sin(\omega + s(\theta_{pj} + 2\pi i))}{1 - 2r_{pj}^s \cos(\omega + s(\theta_{pj} + 2\pi i)) + r_{pj}^{2s}} - \cdots \right. \\
&\quad \left. \cdots \frac{\sin(\omega - s(\theta_{pj} + 2\pi i))}{1 - 2r_{pj}^s \cos(\omega - s(\theta_{pj} + 2\pi i)) + r_{pj}^{2s}} \right\}
\end{aligned}$$

The partial derivatives of the phase are

$$\begin{aligned}
\frac{\partial P(\omega)}{\partial K} &= 0 \\
\frac{\partial P(\omega)}{\partial R_{0j}} &= \frac{\sin \omega}{1 - 2R_{0j} \cos \omega + R_{0j}^2} \\
\frac{\partial P(\omega)}{\partial R_{pj}} &= -sR_{pj}^{s-1} \sum_{i=0}^{R-1} \frac{\sin(\omega - s2\pi i)}{1 - 2R_{pj}^s \cos(\omega - s2\pi i) + R_{pj}^{2s}}
\end{aligned}$$

For convenience, write

$$\begin{aligned}
P_{0N} &= \sin 2\omega - 2r_{0j} \cos \theta_{0j} \sin \omega \\
P_{0D} &= \cos 2\omega - 2r_{0j} \cos \theta_{0j} \cos \omega + r_{0j}^2
\end{aligned}$$

then

$$\begin{aligned}
\frac{\partial P(\omega)}{\partial r_{0j}} &= P_{0N} \frac{(2 \cos \theta_{0j} \cos \omega - 2r_{0j})}{P_{0N}^2 + P_{0D}^2} - P_{0D} \frac{2 \cos \theta_{0j} \sin \omega}{P_{0N}^2 + P_{0D}^2} \\
\frac{\partial P(\omega)}{\partial \theta_{0j}} &= P_{0D} \frac{2r_{0j} \sin \theta_{0j} \sin \omega}{P_{0N}^2 + P_{0D}^2} - P_{0N} \frac{2r_{0j} \sin \theta_{0j} \cos \omega}{P_{0N}^2 + P_{0D}^2}
\end{aligned}$$

For convenience, write

$$P_{pN} = \sin 2\omega - 2r_{pj}^s \cos [s(\theta_{pj} + 2\pi i)] \sin \omega$$

$$P_{pD} = \cos 2\omega - 2r_{pj}^s \cos [s(\theta_{pj} + 2\pi i)] \cos \omega + r_{pj}^{2s}$$

then

$$\frac{\partial P(\omega)}{\partial r_{pj}} = - \sum_{i=0}^{R-1} \left\{ P_{pD} \frac{-2sr_{pj}^{s-1} \cos [s(\theta_{pj} + 2\pi i)] \sin \omega}{P_{pN}^2 + P_{pD}^2} - P_{pN} \frac{-2sr_{pj}^{s-1} \cos [s(\theta_{pj} + 2\pi i)] \cos \omega + 2sr_{pj}^{2s-1}}{P_{pN}^2 + P_{pD}^2} \right\}$$

$$\frac{\partial P(\omega)}{\partial \theta_{pj}} = - \sum_{i=0}^{R-1} \left\{ P_{pD} \frac{2sr_{pj}^s \sin [s(\theta_{pj} + 2\pi i)] \sin \omega}{P_{pN}^2 + P_{pD}^2} - P_{pN} \frac{2sr_{pj}^s \sin [s(\theta_{pj} + 2\pi i)] \cos \omega}{P_{pN}^2 + P_{pD}^2} \right\}$$

The partial derivatives of the group delay are

$$\begin{aligned} \frac{\partial T(\omega)}{\partial K} &= 0 \\ \frac{\partial T(\omega)}{\partial R_{0j}} &= \frac{2R_{0j} - (R_{0j}^2 + 1) \cos \omega}{[1 - 2R_{0j} \cos \omega + R_{0j}^2]^2} \\ \frac{\partial T(\omega)}{\partial R_{pj}} &= sR_{pj}^{s-1} \sum_{i=0}^{R-1} \frac{(R_{pj}^{2s} + 1) \cos (\omega - s2\pi i) - 2R_{pj}^s}{[1 - 2R_{pj}^s \cos (\omega - s2\pi i) + R_{pj}^{2s}]^2} \\ \frac{\partial T(\omega)}{\partial r_{0j}} &= \frac{2r_{0j} - (r_{0j}^2 + 1) \cos (\omega - \theta_{0j})}{[1 - 2r_{0j} \cos (\omega - \theta_{0j}) + r_{0j}^2]^2} + \frac{2r_{0j} - (r_{0j}^2 + 1) \cos (\omega + \theta_{0j})}{[1 - 2r_{0j} \cos (\omega + \theta_{0j}) + r_{0j}^2]^2} \\ \frac{\partial T(\omega)}{\partial \theta_{0j}} &= \frac{r_{0j}(r_{0j}^2 - 1) \sin (\omega - \theta_{0j})}{[1 - 2r_{0j} \cos (\omega - \theta_{0j}) + r_{0j}^2]^2} - \frac{r_{0j}(r_{0j}^2 - 1) \sin (\omega + \theta_{0j})}{[1 - 2r_{0j} \cos (\omega + \theta_{0j}) + r_{0j}^2]^2} \\ \frac{\partial T(\omega)}{\partial r_{pj}} &= sr_{pj}^{s-1} \sum_{i=0}^{R-1} \left\{ \frac{(r_{pj}^{2s} + 1) \cos (\omega - s(\theta_{pj} + 2\pi i)) - 2r_{pj}^s}{[1 - 2r_{pj}^s \cos (\omega - s(\theta_{pj} + 2\pi i)) + r_{pj}^{2s}]^2} + \dots \right. \\ &\quad \left. \dots \frac{(r_{pj}^{2s} + 1) \cos (\omega + s(\theta_{pj} + 2\pi i)) - 2r_{pj}^s}{[1 - 2r_{pj}^s \cos (\omega + s(\theta_{pj} + 2\pi i)) + r_{pj}^{2s}]^2} \right\} \\ \frac{\partial T(\omega)}{\partial \theta_{pj}} &= sr_{pj}^s (1 - r_{pj}^{2s}) \sum_{i=0}^{R-1} \left\{ \frac{\sin (\omega - s(\theta_{pj} + 2\pi i))}{[1 - 2r_{pj}^s \cos (\omega - s(\theta_{pj} + 2\pi i)) + r_{pj}^{2s}]^2} - \dots \right. \\ &\quad \left. \dots \frac{\sin (\omega + s(\theta_{pj} + 2\pi i))}{[1 - 2r_{pj}^s \cos (\omega + s(\theta_{pj} + 2\pi i)) + r_{pj}^{2s}]^2} \right\} \end{aligned}$$

The second partial derivatives of the magnitude response are (with $j \neq k$, and otherwise assumed to vary across all indexes):

$$\begin{aligned} \frac{\partial^2 A(\omega)}{\partial K^2} &= 0 \\ \frac{\partial^2 A(\omega)}{\partial K \partial R_{0j}} &= \frac{1}{K} \frac{\partial A(\omega)}{\partial R_{0j}} \\ \frac{\partial^2 A(\omega)}{\partial K \partial R_{pj}} &= \frac{1}{K} \frac{\partial A(\omega)}{\partial R_{pj}} \\ \frac{\partial^2 A(\omega)}{\partial K \partial r_{0j}} &= \frac{1}{K} \frac{\partial A(\omega)}{\partial r_{0j}} \\ \frac{\partial^2 A(\omega)}{\partial K \partial \theta_{0j}} &= \frac{1}{K} \frac{\partial A(\omega)}{\partial \theta_{0j}} \\ \frac{\partial^2 A(\omega)}{\partial K \partial r_{pj}} &= \frac{1}{K} \frac{\partial A(\omega)}{\partial r_{pj}} \\ \frac{\partial^2 A(\omega)}{\partial K \partial \theta_{pj}} &= \frac{1}{K} \frac{\partial A(\omega)}{\partial \theta_{pj}} \\ \frac{\partial^2 A(\omega)}{\partial R_{0j}^2} &= A(\omega) \frac{\sin^2 \omega}{[1 - 2R_{0j} \cos \omega + R_{0j}^2]^2} \end{aligned}$$

$$\begin{aligned}
\frac{\partial^2 A(\omega)}{\partial R_{0k} \partial R_{0j}} &= \frac{\partial A(\omega)}{\partial R_{0k}} \left\{ \frac{R_{0j} - \cos \omega}{1 - 2R_{0j} \cos \omega + R_{0j}^2} \right\} \\

\end{aligned}$$

The results for group delay were calculated with the assistance of the *Maxima* [164] script *delay.max*.

The Octave function *iirA* calculates the amplitude, and partial derivatives and Hessian of the amplitude response of an IIR filter with decimation factor R , U real zeros, V real poles, $\frac{M}{2}$ conjugate zero pairs and $\frac{Q}{2}$ conjugate pole pairs. The Octave script *iirA_test.m* exercises *iirA*. Note that R_0 and r_0 are moved off the unit circle when testing the gradients. Likewise, Octave function *iirT* calculates the group delay, partial derivatives and Hessian of the group delay response of an IIR filter and is exercised by the test script *iirT_test.m*. Again, Octave function *iirP* calculates the phase and partial derivatives of the phase response of an IIR filter and is exercised by the test script *iirP_test.m*.

The Octave function *iirA_parallel.m* uses the *parcellfun* function included in the Octave-Forge *parallel* package [103] to test “parallelising” the calculation of amplitude response and gradients by the *iirA* function over 4 processes. (My Intel i7-7700K CPU has 4 CPUs). No benefit was seen on my PC until the frequency vector length was much longer than those used in the examples.

Appendix F

Gradient of the IIR filter amplitude response with respect to frequency

This section describes the derivatives with respect to angular frequency of the amplitude response, $A(\omega)$, of an IIR filter expressed in gain-pole-zero form. This section derives formulas for $\frac{\partial A(\omega)}{\partial \omega}$, $\frac{\partial^2 A(\omega)}{\partial \omega^2}$ and formulas for the gradients with respect to the gain-pole-zero coefficients, $\frac{\partial^2 A(\omega)}{\partial \omega \partial K}$, $\frac{\partial^2 A(\omega)}{\partial \omega \partial R_{0j}}$, $\frac{\partial^2 A(\omega)}{\partial \omega \partial R_{pj}}$, etc. In this case the denominator polynomial is *not* decimated by R . The squared amplitude response is:

$$A^2(\omega) = K^2 \frac{\prod_{j=1}^U \{1 - 2R_{0j} \cos \omega + R_{0j}^2\} \prod_{j=1}^M \{(1 - 2r_{0j} \cos(\omega - \theta_{0j}) + r_{0j}^2)(1 - 2r_{0j} \cos(\omega + \theta_{0j}) + r_{0j}^2)\}}{\prod_{j=1}^V \{1 - 2R_{pj} \cos \omega + R_{pj}^2\} \prod_{j=1}^Q \{(1 - 2r_{pj} \cos(\omega - \theta_{pj}) + r_{pj}^2)(1 - 2r_{pj} \cos(\omega + \theta_{pj}) + r_{pj}^2)\}}$$

The gradient of the amplitude response with respect to angular frequency is given by:

$$\begin{aligned} \frac{1}{A(\omega)} \frac{\partial A(\omega)}{\partial \omega} &= \sum_{j=1}^U \frac{R_{0j} \sin \omega}{1 - 2R_{0j} \cos \omega + R_{0j}^2} - \sum_{j=1}^V \frac{R_{pj} \sin \omega}{1 - 2R_{pj} \cos \omega + R_{pj}^2} \dots \\ &+ \sum_{j=1}^{\frac{M}{2}} \frac{r_{0j} \sin(\omega - \theta_{0j})}{1 - 2r_{0j} \cos(\omega - \theta_{0j}) + r_{0j}^2} - \sum_{j=1}^{\frac{Q}{2}} \frac{r_{pj} \sin(\omega - \theta_{pj})}{1 - 2r_{pj} \cos(\omega - \theta_{pj}) + r_{pj}^2} \dots \\ &+ \sum_{j=1}^{\frac{M}{2}} \frac{r_{0j} \sin(\omega + \theta_{0j})}{1 - 2r_{0j} \cos(\omega + \theta_{0j}) + r_{0j}^2} - \sum_{j=1}^{\frac{Q}{2}} \frac{r_{pj} \sin(\omega + \theta_{pj})}{1 - 2r_{pj} \cos(\omega + \theta_{pj}) + r_{pj}^2} \end{aligned}$$

The gradients with respect to the coefficients are given by

$$\begin{aligned} -\frac{1}{A^2(\omega)} \frac{\partial A(\omega)}{\partial \omega} \frac{\partial A(\omega)}{\partial K} + \frac{1}{A(\omega)} \frac{\partial^2 A(\omega)}{\partial \omega \partial K} &= 0 \\ -\frac{1}{A^2(\omega)} \frac{\partial A(\omega)}{\partial \omega} \frac{\partial A(\omega)}{\partial R_{0j}} + \frac{1}{A(\omega)} \frac{\partial^2 A(\omega)}{\partial \omega \partial R_{0j}} &= \frac{(1 - R_{0j}^2) \sin \omega}{(1 - 2R_{0j} \cos \omega + R_{0j}^2)^2} \\ -\frac{1}{A^2(\omega)} \frac{\partial A(\omega)}{\partial \omega} \frac{\partial A(\omega)}{\partial R_{pj}} + \frac{1}{A(\omega)} \frac{\partial^2 A(\omega)}{\partial \omega \partial R_{pj}} &= -\frac{(1 - R_{pj}^2) \sin \omega}{(1 - 2R_{pj} \cos \omega + R_{pj}^2)^2} \\ -\frac{1}{A^2(\omega)} \frac{\partial A(\omega)}{\partial \omega} \frac{\partial A(\omega)}{\partial r_{0j}} + \frac{1}{A(\omega)} \frac{\partial^2 A(\omega)}{\partial \omega \partial r_{0j}} &= \frac{(1 - r_{0j}^2) \sin(\omega - \theta_{0j})}{(1 - 2r_{0j} \cos(\omega - \theta_{0j}) + r_{0j}^2)^2} + \frac{(1 - r_{0j}^2) \sin(\omega + \theta_{0j})}{(1 - 2r_{0j} \cos(\omega + \theta_{0j}) + r_{0j}^2)^2} \\ -\frac{1}{A^2(\omega)} \frac{\partial A(\omega)}{\partial \omega} \frac{\partial A(\omega)}{\partial r_{pj}} + \frac{1}{A(\omega)} \frac{\partial^2 A(\omega)}{\partial \omega \partial r_{pj}} &= -\frac{r_{0j}(1 + r_{0j}^2) \cos(\omega - \theta_{0j}) - 2r_{0j}^2}{(1 - 2r_{0j} \cos(\omega - \theta_{0j}) + r_{0j}^2)^2} + \frac{r_{0j}(1 + r_{0j}^2) \cos(\omega + \theta_{0j}) - 2r_{0j}^2}{(1 - 2r_{0j} \cos(\omega + \theta_{0j}) + r_{0j}^2)^2} \\ -\frac{1}{A^2(\omega)} \frac{\partial A(\omega)}{\partial \omega} \frac{\partial A(\omega)}{\partial \theta_{0j}} + \frac{1}{A(\omega)} \frac{\partial^2 A(\omega)}{\partial \omega \partial \theta_{0j}} &= -\frac{(1 - r_{pj}^2) \sin(\omega - \theta_{pj})}{(1 - 2r_{pj} \cos(\omega - \theta_{pj}) + r_{pj}^2)^2} - \frac{(1 - r_{pj}^2) \sin(\omega + \theta_{pj})}{(1 - 2r_{pj} \cos(\omega + \theta_{pj}) + r_{pj}^2)^2} \\ -\frac{1}{A^2(\omega)} \frac{\partial A(\omega)}{\partial \omega} \frac{\partial A(\omega)}{\partial \theta_{pj}} + \frac{1}{A(\omega)} \frac{\partial^2 A(\omega)}{\partial \omega \partial \theta_{pj}} &= \frac{r_{pj}(1 + r_{pj}^2) \cos(\omega - \theta_{pj}) - 2r_{pj}^2}{(1 - 2r_{pj} \cos(\omega - \theta_{pj}) + r_{pj}^2)^2} - \frac{r_{pj}(1 + r_{pj}^2) \cos(\omega + \theta_{pj}) - 2r_{pj}^2}{(1 - 2r_{pj} \cos(\omega + \theta_{pj}) + r_{pj}^2)^2} \end{aligned}$$

The second derivative of the amplitude response with respect to angular frequency is given by:

$$\begin{aligned}
-\left[\frac{1}{A(\omega)} \frac{\partial A(\omega)}{\partial \omega}\right]^2 + \frac{1}{A(\omega)} \frac{\partial^2 A(\omega)}{\partial \omega^2} = & \sum_{j=1}^U \frac{R_{0j} \cos \omega}{1 - 2R_{0j} \cos \omega + R_{0j}^2} - \sum_{j=1}^U \frac{2R_{0j}^2 \sin^2 \omega}{[1 - 2R_{0j} \cos \omega + R_{0j}^2]^2} \dots \\
& - \sum_{j=1}^V \frac{R_{pj} \cos \omega}{1 - 2R_{pj} \cos \omega + R_{pj}^2} + \sum_{j=1}^V \frac{2R_{pj}^2 \sin^2 \omega}{[1 - 2R_{pj} \cos \omega + R_{pj}^2]^2} \dots \\
& + \sum_{j=1}^{\frac{M}{2}} \frac{r_{0j} \cos (\omega - \theta_{0j})}{1 - 2r_{0j} \cos (\omega - \theta_{0j}) + r_{0j}^2} - \sum_{j=1}^{\frac{M}{2}} \frac{2r_{0j}^2 \sin^2 (\omega - \theta_{0j})}{[1 - 2r_{0j} \cos (\omega - \theta_{0j}) + r_{0j}^2]^2} \dots \\
& - \sum_{j=1}^{\frac{Q}{2}} \frac{r_{pj} \cos (\omega - \theta_{pj})}{1 - 2r_{pj} \cos (\omega - \theta_{pj}) + r_{pj}^2} + \sum_{j=1}^{\frac{Q}{2}} \frac{2r_{pj}^2 \sin^2 (\omega - \theta_{pj})}{[1 - 2r_{pj} \cos (\omega - \theta_{pj}) + r_{pj}^2]^2} \dots \\
& + \sum_{j=1}^{\frac{M}{2}} \frac{r_{0j} \cos (\omega + \theta_{0j})}{1 - 2r_{0j} \cos (\omega + \theta_{0j}) + r_{0j}^2} - \sum_{j=1}^{\frac{M}{2}} \frac{2r_{0j}^2 \sin^2 (\omega + \theta_{0j})}{[1 - 2r_{0j} \cos (\omega + \theta_{0j}) + r_{0j}^2]^2} \dots \\
& - \sum_{j=1}^{\frac{Q}{2}} \frac{r_{pj} \cos (\omega + \theta_{pj})}{1 - 2r_{pj} \cos (\omega + \theta_{pj}) + r_{pj}^2} + \sum_{j=1}^{\frac{Q}{2}} \frac{2r_{pj}^2 \sin^2 (\omega + \theta_{pj})}{[1 - 2r_{pj} \cos (\omega + \theta_{pj}) + r_{pj}^2]^2}
\end{aligned}$$

Appendix G

Allpass filter frequency response

G.1 Allpass filter phase response

This section describes the phase response and the gradient of the phase response of an all-pass filter in terms of the pole and zero locations of the transfer function. If $D(z)$ has V real zeros and $\frac{Q}{2}$ pairs of complex conjugate zeros within the unit circle

$$D(z) = \left\{ \prod_{k=1}^V z - R_{pk} \right\} \left\{ \prod_{k=1}^{\frac{Q}{2}} (z - r_{pk} e^{i\theta_{pk}})(z - r_{pk} e^{-i\theta_{pk}}) \right\}$$

where R_{pk} are the real zeros and $r_{pk} e^{\pm i\theta_{pk}}$ are the complex conjugate zeros of $D(z)$.

The all-pass filter transfer function with decimation factor, R , is:

$$\begin{aligned} A(z) &= z^{-R(V+Q)} \frac{D(z^{-R})}{D(z^R)} \\ &= \left\{ \prod_{k=1}^V \frac{z^{-R} - R_{pk}}{1 - R_{pk} z^{-R}} \right\} \left\{ \prod_{k=1}^{\frac{Q}{2}} \frac{z^{-R} - r_{pk} e^{i\theta_{pk}}}{1 - r_{pk} e^{-i\theta_{pk}} z^{-R}} \right\} \left\{ \prod_{k=1}^{\frac{Q}{2}} \frac{z^{-R} - r_{pk} e^{-i\theta_{pk}}}{1 - r_{pk} e^{i\theta_{pk}} z^{-R}} \right\} \end{aligned}$$

The magnitude response of $A(z)$ is $|A(e^{i\omega})| = 1$. The phase response of $A(z)$ is

$$\begin{aligned} P(\omega) &= - \sum_{k=1}^V \left\{ \arctan \frac{R_{pk} \sin R\omega}{1 - R_{pk} \cos R\omega} + \arctan \frac{\sin R\omega}{\cos R\omega - R_{pk}} \right\} \dots \\ &\quad - \sum_{k=1}^{\frac{Q}{2}} \left\{ \arctan \frac{r_{pk} \sin (R\omega + \theta_{pk})}{1 - r_{pk} \cos (R\omega + \theta_{pk})} - \arctan \frac{\sin R\omega + r_{pk} \sin \theta_{pk}}{\cos R\omega - r_{pk} \cos \theta_{pk}} \right\} \dots \\ &\quad - \sum_{k=1}^{\frac{Q}{2}} \left\{ \arctan \frac{r_{pk} \sin (R\omega - \theta_{pk})}{1 - r_{pk} \cos (R\omega - \theta_{pk})} - \arctan \frac{\sin R\omega - r_{pk} \sin \theta_{pk}}{\cos R\omega - r_{pk} \cos \theta_{pk}} \right\} \end{aligned}$$

The partial derivatives of the phase response are:

$$\begin{aligned} \frac{\partial P(\omega)}{\partial R_{pk}} &= - \frac{2 \sin R\omega}{R_{pk}^2 - 2R_{pk} \cos R\omega + 1} \\ \frac{\partial P(\omega)}{\partial r_{pk}} &= - \frac{2 \sin (R\omega - \theta_{pk})}{r_{pk}^2 - 2r_{pk} \cos (R\omega - \theta_{pk}) + 1} - \frac{2 \sin (R\omega + \theta_{pk})}{r_{pk}^2 - 2r_{pk} \cos (R\omega + \theta_{pk}) + 1} \\ \frac{\partial P(\omega)}{\partial \theta_{pk}} &= - \frac{2r_{pk}^2 - 2r_{pk} \cos (R\omega - \theta_{pk})}{r_{pk}^2 - 2r_{pk} \cos (R\omega - \theta_{pk}) + 1} + \frac{2r_{pk}^2 - 2r_{pk} \cos (R\omega + \theta_{pk})}{r_{pk}^2 - 2r_{pk} \cos (R\omega + \theta_{pk}) + 1} \end{aligned}$$

The second partial derivatives of the phase response (on the diagonal of the Hessian matrix only) are:

$$\frac{\partial^2 P(\omega)}{\partial R_{pk}^2} = \frac{4 [R_{pk} - \cos R\omega] \sin R\omega}{[R_{pk}^2 - 2R_{pk} \cos R\omega + 1]^2}$$

$$\begin{aligned}\frac{\partial^2 P(\omega)}{\partial r_{pk}^2} &= \frac{4[r_{pk} - \cos(R\omega - \theta_{pk})]\sin(R\omega - \theta_{pk})}{[r_{pk}^2 - 2r_{pk}\cos(R\omega - \theta_{pk}) + 1]^2} + \frac{4[r_{pk} - \cos(R\omega + \theta_{pk})]\sin(R\omega + \theta_{pk})}{[r_{pk}^2 - 2r_{pk}\cos(R\omega + \theta_{pk}) + 1]^2} \\ \frac{\partial^2 P(\omega)}{\partial \theta_{pk}^2} &= \frac{2r_{pk}\sin(R\omega - \theta_{pk})}{r_{pk}^2 - 2r_{pk}\cos(R\omega - \theta_{pk}) + 1} - \frac{4[r_{pk}^2 - r_{pk}\cos(R\omega - \theta_{pk})]r_{pk}\sin(R\omega - \theta_{pk})}{[r_{pk}^2 - 2r_{pk}\cos(R\omega - \theta_{pk}) + 1]^2} \dots \\ &\quad \frac{2r_{pk}\sin(R\omega + \theta_{pk})}{r_{pk}^2 - 2r_{pk}\cos(R\omega + \theta_{pk}) + 1} - \frac{4[r_{pk}^2 - r_{pk}\cos(R\omega + \theta_{pk})]r_{pk}\sin(R\omega + \theta_{pk})}{[r_{pk}^2 - 2r_{pk}\cos(R\omega + \theta_{pk}) + 1]^2}\end{aligned}$$

The second partial derivatives of the phase response (on the diagonal of the Hessian matrix only) are:

$$\begin{aligned}\frac{\partial^2 P(\omega)}{\partial R_{pk}^2} &= \frac{4[R_{pk} - \cos R\omega]\sin R\omega}{[R_{pk}^2 - 2R_{pk}\cos R\omega + 1]^2} \\ \frac{\partial^2 P(\omega)}{\partial r_{pk}^2} &= \frac{4[r_{pk} - \cos(R\omega - \theta_{pk})]\sin(R\omega - \theta_{pk})}{[r_{pk}^2 - 2r_{pk}\cos(R\omega - \theta_{pk}) + 1]^2} + \frac{4[r_{pk} - \cos(R\omega + \theta_{pk})]\sin(R\omega + \theta_{pk})}{[r_{pk}^2 - 2r_{pk}\cos(R\omega + \theta_{pk}) + 1]^2} \\ \frac{\partial^2 P(\omega)}{\partial \theta_{pk}^2} &= \frac{2r_{pk}\sin(R\omega - \theta_{pk})}{r_{pk}^2 - 2r_{pk}\cos(R\omega - \theta_{pk}) + 1} - \frac{4[r_{pk}^2 - r_{pk}\cos(R\omega - \theta_{pk})]r_{pk}\sin(R\omega - \theta_{pk})}{[r_{pk}^2 - 2r_{pk}\cos(R\omega - \theta_{pk}) + 1]^2} \dots \\ &\quad \frac{2r_{pk}\sin(R\omega + \theta_{pk})}{r_{pk}^2 - 2r_{pk}\cos(R\omega + \theta_{pk}) + 1} - \frac{4[r_{pk}^2 - r_{pk}\cos(R\omega + \theta_{pk})]r_{pk}\sin(R\omega + \theta_{pk})}{[r_{pk}^2 - 2r_{pk}\cos(R\omega + \theta_{pk}) + 1]^2}\end{aligned}$$

The Octave function `allpassP` calculates the phase and partial derivatives of the phase response of an allpass IIR filter and is exercised by the test script `allpassP_test.m`.

G.2 Allpass filter group delay response

This section describes the group delay response and the gradient of the group delay response of an all-pass filter in terms of the pole and zero locations of the transfer function. The phase response, $P(\omega)$, of the allpass filter is derived in Section G.1. The group delay of the allpass filter is:

$$\begin{aligned}T(\omega) &= -R \sum_{k=1}^V \frac{R_{pk}^2 - 1}{R_{pk}^2 - 2R_{pk}\cos R\omega + 1} \dots \\ &\quad -R \sum_{k=1}^{\frac{Q}{2}} \frac{r_{pk}^2 - 1}{r_{pk}^2 - 2r_{pk}\cos(R\omega + \theta_{pk}) + 1} \dots \\ &\quad -R \sum_{k=1}^{\frac{Q}{2}} \frac{r_{pk}^2 - 1}{r_{pk}^2 - 2r_{pk}\cos(R\omega - \theta_{pk}) + 1}\end{aligned}$$

The partial derivatives of the group delay with respect to the coefficients are:

$$\begin{aligned}\frac{\partial T(\omega)}{\partial R_{pk}} &= 2R \frac{(R_{pk}^2 + 1)\cos R\omega - 2R_{pk}}{[R_{pk}^2 - 2R_{pk}\cos R\omega + 1]^2} \\ \frac{\partial T(\omega)}{\partial r_{pk}} &= 2R \frac{(r_{pk}^2 + 1)\cos(R\omega + \theta_{pk}) - 2r_{pk}}{[r_{pk}^2 - 2r_{pk}\cos(R\omega + \theta_{pk}) + 1]^2} + 2R \frac{(r_{pk}^2 + 1)\cos(R\omega - \theta_{pk}) - 2r_{pk}}{[r_{pk}^2 - 2r_{pk}\cos(R\omega - \theta_{pk}) + 1]^2} \\ \frac{\partial T(\omega)}{\partial \theta_{pk}} &= 2R \frac{r_{pk}(r_{pk}^2 - 1)\sin(R\omega + \theta_{pk})}{[r_{pk}^2 - 2r_{pk}\cos(R\omega + \theta_{pk}) + 1]^2} - 2R \frac{r_{pk}(r_{pk}^2 - 1)\sin(R\omega - \theta_{pk})}{[r_{pk}^2 - 2r_{pk}\cos(R\omega - \theta_{pk}) + 1]^2}\end{aligned}$$

The second partial derivatives of the group delay response (on the diagonal of the Hessian matrix only) are:

$$\frac{\partial^2 T(\omega)}{\partial R_{pk}^2} = -4R \frac{R_{pk}^3 \cos R\omega - 3R_{pk}^2 + 3R_{pk} \cos R\omega + 1 - 2\cos^2 R\omega}{[R_{pk}^2 - 2R_{pk}\cos R\omega + 1]^3}$$

$$\begin{aligned} \frac{\partial^2 T(\omega)}{\partial r_{pk}^2} &= -4R \frac{r_{pk}^3 \cos(R\omega + \theta_{pk}) - 3r_{pk}^2 + 3r_{pk} \cos(R\omega + \theta_{pk}) + 1 - 2\cos^2(R\omega + \theta_{pk})}{\left[r_{pk}^2 - 2r_{pk} \cos(R\omega + \theta_{pk}) + 1\right]^3} \dots \\ &\quad - 4R \frac{r_{pk}^3 \cos(R\omega - \theta_{pk}) - 3r_{pk}^2 + 3r_{pk} \cos(R\omega - \theta_{pk}) + 1 - 2\cos^2(R\omega - \theta_{pk})}{\left[r_{pk}^2 - 2r_{pk} \cos(R\omega - \theta_{pk}) + 1\right]^3} \dots \\ \frac{\partial^2 T(\omega)}{\partial \theta_{pk}^2} &= 2R \frac{r_{pk}^5 \cos(R\omega + \theta_{pk}) - 2r_{pk}^2 (r_{pk}^2 - 1) [1 + \sin^2(R\omega + \theta_{pk})] - r_{pk} \cos(R\omega + \theta_{pk})}{\left[r_{pk}^2 - 2r_{pk} \cos(R\omega + \theta_{pk}) + 1\right]^3} \dots \\ &\quad + 2R \frac{r_{pk}^5 \cos(R\omega - \theta_{pk}) - 2r_{pk}^2 (r_{pk}^2 - 1) [1 + \sin^2(R\omega - \theta_{pk})] - r_{pk} \cos(R\omega - \theta_{pk})}{\left[r_{pk}^2 - 2r_{pk} \cos(R\omega - \theta_{pk}) + 1\right]^3} \end{aligned}$$

The Octave function *allpassT* calculates the phase and partial derivatives of the group delay response of an allpass IIR filter and is exercised by the test script *allpassT_test.m*.

Appendix H

Gradients of the state variable filter frequency response

Section 1.9.4 shows results for the gradients of the complex response, $H(z)$, with respect to the matrix components of the corresponding state variable filter. This section shows results for the gradients of the squared-magnitude, phase and group delay of a state variable filter. In the following, the components of the state variable filter matrixes A , B , C and D are represented by α , β , γ and δ or more generally, x . The matrix components may themselves be functions of other variables (the k and c coefficients of a Schur lattice filter, for example).

H.1 Gradients of the state variable filter complex frequency response

If the components of the state variable matrixes are functions of a variable x then given $\frac{dA}{dx}$, $\frac{dB}{dx}$, $\frac{dC}{dx}$ and $\frac{dD}{dx}$ and defining $R = (e^{i\omega} I - A)^{-1}$, the gradients of the complex frequency response are:

$$\begin{aligned}\frac{dH}{dx} &= \frac{dC}{dx} RB + CR \frac{dA}{dx} RB + CR \frac{dB}{dx} + \frac{dD}{dx} \\ \frac{d^2H}{dxd\omega} &= -ie^{i\omega} \left[\frac{dC}{dx} RRB + CR \frac{dA}{dx} RRB + CRR \frac{dA}{dx} RB + CRR \frac{dB}{dx} \right] \\ \frac{d^2H}{dx^2} &= \frac{d^2C}{dx^2} RB + 2 \frac{dC}{dx} R \frac{dA}{dx} RB + 2 \frac{dC}{dx} R \frac{dB}{dx} + 2CR \frac{dA}{dx} R \frac{dA}{dx} RB + CR \frac{d^2A}{dx^2} RB + 2CR \frac{dA}{dx} R \frac{dB}{dx} + CR \frac{d^2B}{dx^2} + \frac{d^2D}{dx^2}\end{aligned}$$

and

$$\begin{aligned}\frac{d^3H}{dx^2d\omega} &= -ie^{i\omega} \left[\frac{d^2C}{dx^2} RRB + 2 \frac{dC}{dx} R \frac{dA}{dx} RRB + 2 \frac{dC}{dx} RR \frac{dA}{dx} RB + 2 \frac{dC}{dx} RR \frac{dB}{dx} + \dots \right. \\ &\quad \left. 2CR \frac{dA}{dx} R \frac{dA}{dx} RRB + CR \frac{d^2A}{dx^2} RRB + 2CR \frac{dA}{dx} RR \frac{dA}{dx} RB + 2CR \frac{dA}{dx} RR \frac{dB}{dx} + \dots \right. \\ &\quad \left. 2CRR \frac{dA}{dx} R \frac{dA}{dx} RB + CRR \frac{d^2A}{dx^2} RB + 2CRR \frac{dA}{dx} R \frac{dB}{dx} + CRR \frac{d^2B}{dx^2} \right]\end{aligned}$$

The Octave function *Abcd2H* calculates these gradients under the assumption that the components of the state variable matrixes A , B , C and D are linear functions of x and $\frac{d^2A}{dx^2} = \frac{d^2B}{dx^2} = \frac{d^2C}{dx^2} = \frac{d^2D}{dx^2} = 0$.

H.2 State variable filter squared-magnitude response

The squared-magnitude response of a state variable filter is:

$$|H(z)|^2 = \Re H(z)^2 + \Im H(z)^2$$

The gradients of the squared-magnitude response of the filter with respect to the state variable coefficients, α , β , etc., are:

$$\frac{\partial}{\partial x} |H(z)|^2 = 2 \left[\Im H(z) \Im \frac{\partial H(z)}{\partial x} + \Re H(z) \Re \frac{\partial H(z)}{\partial x} \right]$$

where x represents the components of the state variable matrixes. The diagonal of the Hessian matrix of the squared-magnitude (that is the second differentials of the squared-magnitude) is:

$$\frac{\partial^2 |H(z)|^2}{\partial x^2} = 2 \left[\left| \frac{\partial H(z)}{\partial x} \right|^2 + \Im H(z) \Im \frac{\partial^2 H(z)}{\partial x^2} + \Re H(z) \Re \frac{\partial^2 H(z)}{\partial x^2} \right]$$

where:

$$\frac{\partial^2 H(z)}{\partial \alpha^2} = 2C(zI - A)^{-1} \frac{\partial A}{\partial \alpha} (zI - A)^{-1} \frac{\partial A}{\partial \alpha} (zI - A)^{-1} B + C(zI - A)^{-1} \frac{\partial^2 A}{\partial \alpha^2} (zI - A)^{-1} B$$

and

$$\frac{\partial^2 H(z)}{\partial \beta^2} = \frac{\partial^2 H(z)}{\partial \gamma^2} = \frac{\partial^2 H(z)}{\partial \delta^2} = 0$$

H.3 State variable filter phase response

The phase response, $P(z)$, of the state variable filter is:

$$P(z) = \arctan \frac{\Im H(z)}{\Re H(z)}$$

The gradients of the phase response of the filter with respect to the state variable coefficients, α , β , etc., are given by:

$$|H(z)|^2 \frac{\partial P(z)}{\partial x} = \Re H(z) \Im \frac{\partial H(z)}{\partial x} - \Im H(z) \Re \frac{\partial H(z)}{\partial x}$$

where x represents the components of the state variable matrixes. The diagonal of the Hessian matrix of the phase (that is the second differentials of the phase) is given by:

$$\frac{\partial |H(z)|^2}{\partial x} \frac{\partial P(z)}{\partial x} + |H(z)|^2 \frac{\partial^2 P(z)}{\partial x^2} = \Re H(z) \Im \frac{\partial^2 H(z)}{\partial x^2} - \Im H(z) \Re \frac{\partial^2 H(z)}{\partial x^2}$$

H.4 State variable filter group-delay response

The group delay response, $T(\omega)$, of the state variable filter is

$$T(\omega) = -\frac{\partial}{\partial \omega} \arctan \frac{\Im H(\omega)}{\Re H(\omega)}$$

so that

$$|H(\omega)|^2 T(\omega) = - \left[\Re H(\omega) \Im \frac{\partial H(\omega)}{\partial \omega} - \Im H(\omega) \Re \frac{\partial H(\omega)}{\partial \omega} \right]$$

where

$$\frac{\partial H(\omega)}{\partial \omega} = -ie^{i\omega} C(e^{i\omega} I - A)^{-2} B$$

The gradients of the group delay response with respect to the state variable coefficients, α , β , etc., are given by:

$$\begin{aligned} & 2 \left[\Re H(\omega) \Re \frac{\partial H(\omega)}{\partial \alpha} + \Im H(\omega) \Im \frac{\partial H(\omega)}{\partial \alpha} \right] T(\omega) + |H(\omega)|^2 \frac{\partial T(\omega)}{\partial \alpha} = \\ & - \left[\Re \frac{\partial H(\omega)}{\partial \alpha} \Im \frac{\partial H(\omega)}{\partial \omega} + \Re H(\omega) \Im \frac{\partial^2 H(\omega)}{\partial \alpha \partial \omega} - \Im \frac{\partial H(\omega)}{\partial \alpha} \Re \frac{\partial H(\omega)}{\partial \omega} - \Im H(\omega) \Re \frac{\partial^2 H(\omega)}{\partial \alpha \partial \omega} \right] \end{aligned}$$

etc. where

$$\frac{\partial^2 H(\omega)}{\partial \alpha \partial \omega} = -ie^{i\omega} C(e^{i\omega} I - A)^{-1} \left[(e^{i\omega} I - A)^{-1} \frac{\partial A}{\partial \alpha} + \frac{\partial A}{\partial \alpha} (e^{i\omega} I - A)^{-1} \right] (e^{i\omega} I - A)^{-1} B$$

$$\frac{\partial^2 H(\omega)}{\partial \beta \partial \omega} = -ie^{i\omega} C (e^{i\omega} I - A)^{-2}$$

$$\frac{\partial^2 H(\omega)}{\partial \gamma \partial \omega} = -ie^{i\omega} (e^{i\omega} I - A)^{-2} B$$

$$\frac{\partial^2 H(\omega)}{\partial \delta \partial \omega} = 0$$

The diagonal of the Hessian matrix of the group-delay (that is the second differentials of the group-delay) is given by:

$$\begin{aligned} \frac{\partial^2 |H|^2}{\partial x^2} T + 2 \frac{\partial |H|^2}{\partial x} \frac{\partial T}{\partial x} + |H|^2 \frac{\partial^2 T}{\partial x^2} &= -\Re \frac{\partial^2 H}{\partial x^2} \Im \frac{\partial H}{\partial \omega} - \Re \frac{\partial H}{\partial x} \Im \frac{\partial^2 H}{\partial x \partial \omega} - \Re \frac{\partial H}{\partial x} \Im \frac{\partial^2 H}{\partial x \partial \omega} - \Re H \Im \frac{\partial^3 H}{\partial x^2 \partial \omega} \dots \\ &\quad + \Im \frac{\partial^2 H}{\partial x^2} \Re \frac{\partial H}{\partial \omega} + \Im \frac{\partial H}{\partial x} \Re \frac{\partial^2 H}{\partial x \partial \omega} + \Im \frac{\partial H}{\partial x} \Re \frac{\partial^2 H}{\partial x \partial \omega} + \Im H \Re \frac{\partial^3 H}{\partial x^2 \partial \omega} \end{aligned}$$

where x represents the components of the state variable matrixes and:

$$\begin{aligned} \frac{\partial^3 H(\omega)}{\partial \alpha^2 \partial \omega} &= -ie^{i\omega} C (e^{i\omega} I - A)^{-1} \left[2 \frac{\partial A}{\partial \alpha} (e^{i\omega} I - A)^{-2} \frac{\partial A}{\partial \alpha} + \dots \right. \\ &\quad 2 (e^{i\omega} I - A)^{-1} \frac{\partial A}{\partial \alpha} (e^{i\omega} I - A)^{-1} \frac{\partial A}{\partial \alpha} + \dots \\ &\quad 2 \frac{\partial A}{\partial \alpha} (e^{i\omega} I - A)^{-1} \frac{\partial A}{\partial \alpha} (e^{i\omega} I - A)^{-1} + \dots \\ &\quad \left. (e^{i\omega} I - A)^{-1} \frac{\partial^2 A}{\partial \alpha^2} + \frac{\partial^2 A}{\partial \alpha^2} (e^{i\omega} I - A)^{-1} \right] (e^{i\omega} I - A)^{-1} B \end{aligned}$$

Appendix I

Constrained non-linear optimisation

The following largely follows *Ruszczynski* [8] with some contributions concerning heuristics from *Powell* [88] and *Nocedal and Wright* [69].

I.1 Newton's method for a quadratic function

Consider a quadratic approximation, $f^k(x)$, to a function $f(x)$ evaluated at a point x^k

$$f^k(x) = f(x^k) + \nabla_x f(x^k)(x - x^k) + \frac{1}{2}(x - x^k)^T \nabla_{xx}^2 f(x^k)(x - x^k)$$

where $\nabla_{xx}^2 f(x^k)$ is a positive-definite matrix^a (the Hessian matrix). At an optimum point $\nabla_x f^k(x) = 0$ so, approximating the gradient with the first two terms of $f^k(x)$:

$$\nabla_x f(x^k) + \nabla_{xx}^2 f(x^k)(x - x^k) = 0$$

Accordingly, given a pair $(x^k, f(x^k))$, *Newton's method of tangents* gives the next approximation to the location of the optimum point as

$$x^{k+1} = x^k - \tau^k [\nabla_{xx}^2 f(x^k)]^{-1} \nabla_x f(x^k)$$

where τ^k is a stepsize.

I.2 Lagrange multipliers

Consider the problem

$$\begin{aligned} & \text{minimise} && f(x) \\ & \text{subject to} && g(x) = c \end{aligned}$$

where $g(x)$ may represent a set of constraints $\{g_j(x) \mid j \in \mathcal{K}\}$. When a contour of $g(x)$ is tangent to a contour of $f(x)$ the gradients $\nabla_x f(x)$ and $\nabla_x g(x)$ are parallel at that point. (See *Nocedal and Wright* [69, p. 309] for a justification). The method of *Lagrange multipliers* defines an auxilliary function (or *Lagrangian*):

$$\mathcal{L}(x, \lambda) = f(x) - \lambda(g(x) - c)$$

and solves

$$\nabla_{x,\lambda} \mathcal{L}(x, \lambda) = 0$$

Note that the solution may be a saddle point of $\mathcal{L}(x, \lambda)$. The coefficients of the vector λ are the *Lagrange multipliers*.

^a $Q \in \mathbb{R}^{n \times n}$ is positive-definite if $x^T Q x > 0$ for all nonzero $x \in \mathbb{R}^n$

I.3 The dual problem

Define the *dual function* as:

$$q(\lambda) = \min_x \mathcal{L}(x, \lambda)$$

The *dual problem* is:

$$\begin{aligned} & \text{maximise} && q(\lambda) \\ & \text{subject to} && \lambda \geq 0 \end{aligned}$$

Nocedal and Wright [69, Example 12.12] give an example of the dual problem of a quadratic programming problem:

$$\begin{aligned} & \text{minimise} && a^T x + \frac{1}{2} x^T H x \\ & \text{subject to} && Gx - b \geq 0 \end{aligned}$$

where H is a symmetric positive-definite matrix. The Lagrangian function of the dual problem is:

$$q(\lambda) = a^T x + \frac{1}{2} x^T H x - \lambda^T (Gx - b)$$

Since H is positive definite and the Lagrangian is a strictly *convex*^b quadratic function, the minimum occurs at $\nabla q(\lambda) = 0$:

$$a + Hx - G^T \lambda = 0$$

Substituting for x :

$$q(\lambda) = -\frac{1}{2} (G^T \lambda - a)^T H^{-1} (G^T \lambda - a) + b^T \lambda$$

Bertsekas [26, Proposition 3.4.2] gives the following duality theorem:

1. If the primal problem has an optimal solution then the dual problem also has an optimal solution and the corresponding optimal values are equal
2. In order for \tilde{x} to be an optimal primal solution and $\tilde{\lambda}$ to be an optimal dual solution, it is necessary and sufficient that \tilde{x} is primal feasible, $\tilde{\lambda} \geq 0$, $\tilde{\lambda}_j = 0$ over the set of active constraints and $(\tilde{x}, \tilde{\lambda})$ is a solution of the dual problem.

A *primal-dual* or *interior-point* method solves the primal and dual problems simultaneously. At each iteration both sets of constraints are satisfied.

I.4 Karush-Kuhn-Tucker conditions for constrained optimisation

The *Karush-Kuhn-Tucker* conditions generalise the method of Lagrange multipliers to handle inequality constraints. Consider the minimisation problem:

$$\begin{aligned} & \text{minimise} && f(x), \quad x \in \mathbb{R}^n \\ & \text{subject to} && g_i(x) \geq 0, \quad i = 1, \dots, m \\ & && \text{and} \quad h_j(x) = 0, \quad j = 1, \dots, p \end{aligned}$$

where $f : \mathbb{R}^n \rightarrow \mathbb{R}$, $g_i : \mathbb{R}^n \rightarrow \mathbb{R}$ and $h_j : \mathbb{R}^n \rightarrow \mathbb{R}$ are continuous differentiable functions. Define the Lagrangian of the problem as:

$$\mathcal{L}(x, \lambda, \mu) = f(x) - \sum_{i=1}^m \lambda_i g_i(x) - \sum_{j=1}^p \mu_j h_j(x) \triangleq f(x) - \langle \lambda, g \rangle - \langle \mu, h \rangle$$

^bA function, $f(x)$, is convex if $f(\alpha x + (1 - \alpha)y) \leq \alpha f(x) + (1 - \alpha)f(y)$, $\forall \alpha \in [0, 1]$

Define a saddle point of the Lagrangian as:

$$(\tilde{x}, \tilde{\lambda}, \tilde{\mu}) \quad \text{such that} \quad \mathcal{L}(\tilde{x}, \tilde{\lambda}, \tilde{\mu}) = \max_{\lambda, \mu \geq 0} \min_x \mathcal{L}(x, \lambda, \mu)$$

so that

$$\min_x \mathcal{L}(x, \lambda, \mu) \leq \max_{\lambda, \mu \geq 0} \min_x \mathcal{L}(x, \lambda, \mu) \leq \max_{\lambda, \mu \geq 0} \mathcal{L}(x, \lambda, \mu)$$

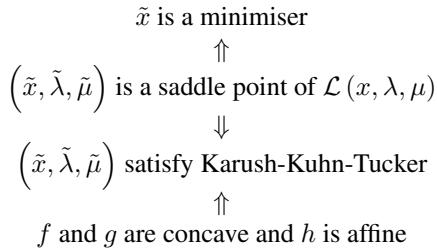

It can be shown that each such saddle point satisfies the *Karush-Kuhn-Tucker* conditions:

$$\begin{aligned} \nabla_x \mathcal{L}(\tilde{x}, \tilde{\lambda}, \tilde{\mu}) &= \nabla_x f(\tilde{x}) - \langle \lambda, \nabla_x g(\tilde{x}) \rangle - \langle \mu, \nabla_x h(\tilde{x}) \rangle = 0 \\ g_i(\tilde{x}) &\geq 0 \\ h_j(\tilde{x}) &= 0 \\ \tilde{\lambda}_i &\geq 0 \\ \tilde{\mu}_j &\geq 0 \\ \langle \lambda, g(\tilde{x}) \rangle &= 0 \end{aligned}$$

For the *cone*^c $C = \mathbb{R}_+^m \times \mathbb{R}^p$, then these conditions can be expressed

$$\begin{aligned} \nabla_x \mathcal{L}(\tilde{x}, \tilde{\lambda}, \tilde{\mu}) &= 0 \\ \begin{bmatrix} g(\tilde{x}) \\ h(\tilde{x}) \end{bmatrix} &\in N_C(\tilde{\lambda}, \tilde{\mu}) \end{aligned}$$

Furthermore, these conditions are necessary and sufficient for \tilde{x} to be a minimiser of $f(x)$. In other words:

For any point x , the set of inequality constraints, \mathcal{K} , can be partitioned into a set of *active* constraints

$$\mathcal{A}(x) = \{i \mid g_i(x) = 0\}$$

and the corresponding set of *inactive* constraints, for which $i \notin \mathcal{A}(x)$. Following *Bertsekas* [26, Section 3.3], note that “if \tilde{x} is a local minimum of the inequality constrained problem, then \tilde{x} is also a local minimum of the identical problem for which the inactive constraints at \tilde{x} have been discarded. On the other hand, at a local minimum, active inequality constraints can be treated to a large extent as equalities”.

I.5 Constrained optimisation using Newton’s method

Consider the non-linear optimization problem of Section I.4. Motivated by Newton’s method, at a given point $(\bar{x}, \bar{\lambda}, \bar{\mu})$ construct an approximation to the *Karush-Kuhn-Tucker* conditions that is linearised at \bar{x} :

$$\begin{aligned} \nabla_x \mathcal{L}(\bar{x}, \bar{\lambda}, \bar{\mu}) + \nabla_{xx}^2 \mathcal{L}(\bar{x}, \bar{\lambda}, \bar{\mu})(x - \bar{x}) &= 0 \\ \begin{bmatrix} g(\bar{x}) + \nabla_x g(\bar{x})(x - \bar{x}) \\ h(\bar{x}) + \nabla_x h(\bar{x})(x - \bar{x}) \end{bmatrix} &\in N_C(\lambda, \mu) \end{aligned}$$

These are the necessary conditions of optimality for *sequential quadratic programming*, shown in Algorithm I.1.

^cFrom Ruszczynski [8, p.26], a set $K \subset \mathbb{R}^n$ is called a cone if for every $x \in K$ and all $\alpha > 0$ has $\alpha x \in K$. From [8, p.28], the set $K^\circ \triangleq \{y \in \mathbb{R}^n : \langle y, x \rangle \leq 0 \forall x \in K\}$ is called the polar cone of K . From [8, p.37], for a convex closed set $X \subset \mathbb{R}^n$ and a point $x \in X$, the set $N_X(x) \triangleq [\text{cone}(X - x)]^\circ$ is called the normal cone to X at x .

Algorithm I.1 The sequential quadratic programming method

At iteration k , given the current approximation of the solution x^k and multipliers (λ^k, μ^k) solve the tangent quadratic programming problem:

$$\begin{aligned} & \text{minimise} \quad \langle \nabla_x f(x^k), d^k \rangle + \frac{1}{2} \left\langle d^{kT}, \nabla_{xx}^2 \mathcal{L}(x^k, \lambda^k, \mu^k), d^k \right\rangle \\ & \text{subject to} \quad g(x^k) + \nabla_x g(x^k) d^k \leq 0 \\ & \quad h(x^k) + \nabla_x h(x^k) d^k = 0 \end{aligned}$$

Denote the solution to this problem by d^k and the Lagrange multipliers associated with the constraints by $\hat{\lambda}^k$ and $\hat{\mu}^k$. Update the approximate solution by:

$$\begin{aligned} x^{k+1} &= x^k + \tau^k d^k \\ \lambda^{k+1} &= \hat{\lambda}^k \\ \mu^{k+1} &= \hat{\mu}^k \end{aligned}$$

and continue. Here $\tau^k \in (0, 1]$ is a step-size coefficient.

I.6 Local convergence

For simplicity, $\tau^k = 1$ and assume there are only inequality constraints ($p = 0$). Also assume that the objective function $f(x)$ has a minimum \tilde{x} , at which the gradients of active constraints, $\nabla_x g_i(\tilde{x})$, $i \in \mathcal{A}(\tilde{x}) = \{1 \leq i \leq m \mid g_i(\tilde{x}) = 0\}$ are linearly independent. In this case the Lagrange multipliers $\hat{\lambda}$ exist and are unique.

Consider the system of non-linear equations:

$$\begin{aligned} \nabla_x f(x) - \sum_{i \in \mathcal{A}(x)} \lambda_i \nabla_x g_i(x) &= 0 \\ g_i(x) &= 0 \end{aligned}$$

These are the necessary conditions of a modification of the original minimisation problem in which the active inequality constraints are treated as equalities. The iterates of the sequential programming method are the iterates of Newton's method for this system. For the current iterate (x^k, λ^k) , define the matrices:

$$\begin{aligned} \mathcal{H}_k &= \nabla_{xx}^2 \mathcal{L}(x^k, \lambda^k) \\ \mathcal{B}_k &= \{\nabla_x g_i(x^k)\} \end{aligned}$$

where $i \in \mathcal{A}(x^k)$ and the columns of \mathcal{B}_k correspond to the gradient vectors. When the above equations are linearised, Newton's method takes the form:

$$\begin{aligned} [\nabla_x f(x^k) - \mathcal{B}_k \lambda^{k+1}] + \mathcal{H}_k d^k &= 0 \\ g_i(x^k) + \mathcal{B}_k^T d^k &= 0 \end{aligned}$$

where λ^{k+1} and $g(x^k)$ are the vectors with coordinates λ_i and $g_i(x^k)$, for $i \in \mathcal{A}(x^k)$. This system can be simplified to:

$$\begin{aligned} \mathcal{H}_k d^k - \mathcal{B}_k \lambda^{k+1} &= -\nabla_x f(x^k) \\ -\mathcal{B}_k^T d^k &= g(x^k) \end{aligned}$$

which can be solved for the direction d^k and the multipliers λ^{k+1} :

$$\lambda^{k+1} = -(\mathcal{B}_k^T \mathcal{H}_k^{-1} \mathcal{B}_k)^{-1} [g(x^k) - \mathcal{B}_k^T \mathcal{H}_k^{-1} \nabla_x f(x^k)] \quad (\text{I.1})$$

$$d^k = -\mathcal{H}_k^{-1} [\nabla_x f(x^k) - \mathcal{B}_k \lambda^{k+1}] \quad (\text{I.2})$$

I.7 Quasi-Newton methods

Consider a modified version of the tangent quadratic programming problem

$$\text{minimise} \quad \nabla_x f(x^k) d^k + \frac{1}{2} d^{kT} \mathcal{W}_k d^k$$

$$\begin{aligned}\text{subject to} \quad & g(x^k) + \nabla_x g(x^k) d^k \leq 0 \\ & h(x^k) + \nabla_x h(x^k) d^k = 0\end{aligned}$$

where the Hessian of the Lagrangian $\nabla_{xx}^2 \mathcal{L}(x^k, \lambda^k, \mu^k)$ is replaced by the positive definite matrix \mathcal{W}_k , guaranteeing that this is a convex quadratic programming problem. The following subsections describe methods for constructing the matrix \mathcal{W}_k .

I.7.1 Updating \mathcal{W}_k with the *Broyden-Fletcher-Goldfarb-Shanno (BFGS) formula*

Typically, $\mathcal{W}_0 = I$. For convenience, set $\delta_k = \tau^k d^k$. The update to \mathcal{W}_k should depend on \mathcal{W}_k and the difference in gradients of the Lagrangian

$$\gamma_k = \nabla_x \mathcal{L}(x^k + \delta_k, \lambda^k, \mu^k) - \nabla_x \mathcal{L}(x^k, \lambda^k, \mu^k)$$

When there are no constraints it is possible to choose the step-length, τ^k , so that the scalar product $\delta_k^T \gamma_k$ is positive. On the other hand, when there are constraints, it can happen that $\delta_k^T \gamma_k$ is negative for all non-zero values of τ^k . In this case the usual methods for updating \mathcal{W}_k would fail to make the update positive definite. Powell [88, p.148] proposes updating \mathcal{W}_k as follows. First replace γ_k with

$$\eta_k = \theta_k \gamma_k + (1 - \theta_k) \mathcal{W}_k \delta_k, \quad 0 \leq \theta_k \leq 1$$

where

$$\theta_k = \begin{cases} 1 & \delta_k^T \gamma_k \geq 0.2 \delta_k^T \mathcal{W}_k \delta_k \\ \frac{0.8 \delta_k^T \mathcal{W}_k \delta_k}{\delta_k^T \mathcal{W}_k \delta_k - \delta_k^T \gamma_k} & \delta_k^T \gamma_k < 0.2 \delta_k^T \mathcal{W}_k \delta_k \end{cases} \quad (\text{I.3})$$

The factor of 0.2 was chosen empirically. Now update \mathcal{W}_k with the *Broyden-Fletcher-Goldfarb-Shanno (BFGS) formula*

$$W_{k+1} = \mathcal{W}_k - \frac{\mathcal{W}_k \delta_k (\mathcal{W}_k \delta_k)^T}{\delta_k^T \mathcal{W}_k \delta_k} + \frac{\eta_k \eta_k^T}{\delta_k^T \eta_k}$$

and update \mathcal{W}_k^{-1} with the *Sherman-Morrison formula*

$$W_{k+1}^{-1} = \mathcal{W}_k^{-1} + \left[1 + \frac{\eta_k^T \mathcal{W}_k^{-1} \eta_k}{\delta_k^T \eta_k} \right] \left(\frac{\delta_k \delta_k^T}{\delta_k^T \eta_k} \right) - \left[\frac{\mathcal{W}_k^{-1} \eta_k \delta_k^T + \delta_k \eta_k^T \mathcal{W}_k^{-1}}{\delta_k^T \eta_k} \right]$$

Note that η and δ are column vectors and $\delta \eta^T$ is a *dyadic* or *Kronecker* product also written $\delta \otimes \eta$. Nocedal and Wright [69, Procedure 18.2] refer to Equation I.3 as *damped BFGS updating*.

I.7.2 A modified Cholesky factorisation of the Hessian

Bertsekas [26, Appendix D] describes implementation of Newton's method by Cholesky factorisation of an approximation to the Hessian, $\nabla_{xx}^2 \mathcal{L}(x^k) + \Delta_k$, that is positive definite.

Algorithm I.2 shows the Cholesky factorisation of a positive definite symmetric matrix, W , as LL^T where L is lower triangular. Firstly, define W_i to be the i -th leading principal submatrix of W :

$$W_i = \begin{bmatrix} w_{1,1} & w_{1,2} & \cdots & w_{1,i} \\ w_{2,1} & w_{2,2} & \cdots & w_{2,i} \\ \vdots & \vdots & \ddots & \vdots \\ w_{i,1} & w_{i,2} & \cdots & w_{i,i} \end{bmatrix}$$

This matrix is positive definite since, for any $y \in \mathbb{R}^i$, $y \neq 0$

$$y^T W_i y = \begin{bmatrix} y^T & 0 \end{bmatrix} W \begin{bmatrix} y \\ 0 \end{bmatrix} > 0$$

The scalar λ_{ii} can be seen to be well-defined by setting $b = W_{i-1}^T \beta_i$ and recalling that W_i is positive definite:

$$0 < \begin{bmatrix} b^T & -1 \end{bmatrix} W_i \begin{bmatrix} b \\ -1 \end{bmatrix} = b^T W_{i-1} b - 2b^T \beta_i + w_{ii}$$

Algorithm I.2 Cholesky factorisation of an $n \times n$ positive-definite symmetric matrix, W

$$L_1 = \sqrt{w_{1,1}}$$

$$W_1 = L_1 L_1^T$$

for $i = 2, \dots, n$ **do**

$$W_i = \begin{bmatrix} W_{i-1} & \beta_i \\ \beta_i^T & w_{i,i} \end{bmatrix} \text{ where } \beta_i = \begin{bmatrix} w_{1,i} \\ \vdots \\ w_{i-1,i} \end{bmatrix}$$

$$W_i = L_i L_i^T \text{ where } L_i = \begin{bmatrix} L_{i-1} & 0 \\ l_i^T & \lambda_{ii} \end{bmatrix}, l_i = L_{i-1}^{-1} \beta_i \text{ and } \lambda_{i,i} = \sqrt{w_{i,i} - l_i^T l_i}$$

end for

$$W = L_n L_n^T$$

$$\begin{aligned} &= w_{ii} - b^T \beta_i \\ &= w_{ii} - \beta_i^T W_{i-1}^{-1} \beta_i \\ &= w_{ii} - (L_{i-1}^{-1} \beta_i)^T (L_{i-1}^{-1} \beta_i) \\ &= w_{ii} - l_i^T l_i \end{aligned}$$

Note that matrix inversion of an arbitrary matrix is an $\mathcal{O}(n^3)$ operation whereas matrix inversion of a triangular matrix via backward or forward substitution is an $\mathcal{O}(n^2)$ operation^d.

We wish to add a diagonal correction, Δ_k , to the Hessian matrix such that the resulting matrix is positive definite whilst simultaneously factoring $\nabla_{xx}^2 \mathcal{L}(x^k) + \Delta_k$. Firstly, fix two positive scalars μ_1 and μ_2 , where $\mu_1 < \mu_2$. The first column of the factor L is given by

$$l_{11} = \begin{cases} \sqrt{w_{11}} & \mu_1 < w_{11} \\ \sqrt{\mu_2} & \text{otherwise} \end{cases}$$

$$l_{i1} = \frac{w_{i1}}{l_{11}} \quad i = 2, \dots, n$$

Given columns $1, 2, \dots, j-1$ of L the elements of the j -th column are

$$l_{jj} = \begin{cases} \sqrt{w_{jj} - \sum_{m=1}^{j-1} l_{jm}^2} & \mu_1 < w_{jj} - \sum_{m=1}^{j-1} l_{jm}^2 \\ \sqrt{\mu_2} & \text{otherwise} \end{cases}$$

$$l_{ij} = \frac{w_{ij} - \sum_{m=1}^{j-1} l_{jm} l_{im}}{l_{jj}} \quad i = j+1, \dots, n$$

This scheme can be used in a modified Newton's method, where at the k -th iteration, we add a diagonal correction, Δ^k , to the Hessian, $\nabla_{xx}^2 \mathcal{L}(x^k)$, and simultaneously obtain a Cholesky factorisation of $\nabla_{xx}^2 \mathcal{L}(x^k) + \Delta^k$. The direction vector, d^k , is found by solving the triangular systems

$$L_k y = -\nabla_x f(x^k)$$

$$L_k^T d^k = y$$

The next point is found by

$$x^{k+1} = x^k + \tau^k d^k$$

where τ^k is a step size. The scalars μ_1 and μ_2 are selected as follows: at each iteration we find the maximum absolute value of the Hessian diagonal elements

$$w^k = \max \text{ element} \{ \nabla_{xx}^2 \mathcal{L}(x^k) \}$$

and set $\mu_1 = r_1 w^k$ and $\mu_2 = r_2 w^k$. The scalar r_1 is set at some “small” (or zero) value. The scalar r_2 is modified at each iteration: if $\tau^k < 0.2$ then $r_2 = 5r_2$; otherwise if $\tau^k > 0.9$ then $r_2 = \frac{r_2}{5}$.

^dThe LDL^T factorisation of a symmetric matrix avoids taking the square-root. See [38, Algorithm 4.1.2].

I.7.3 Wright's modification for degenerate constraints

For the filter design problem, the gradients of upper and lower constraints on the radius and angle of the poles and zeros are not linearly independent and the resulting Jacobian matrix is degenerate. The *singular value decomposition* [38, Sections 2.5.3 and 5.5] finds the minimum 2-norm solution of a degenerate matrix equation as follows: if B is a real $m \times n$ matrix, then there exist orthogonal matrices $U = [u_1, \dots, u_m] \in \mathbb{R}^{m \times m}$ and $V = [v_1, \dots, v_n] \in \mathbb{R}^{n \times n}$ such that

$$U^T B V = \text{diag}(\sigma_1, \dots, \sigma_p) \in \mathbb{R}^{m \times n}$$

where $[u_1, \dots, u_m]$ is a column partitioning of U , $p = \min(m, n)$ and $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_p \geq 0$. From *Golub and Van Loan* [38, Section 5.5.4], the *pseudo-inverse* of B is defined to be $B^* = V \Sigma U^T$ where

$$\Sigma = \text{diag}\left(\frac{1}{\sigma_1}, \dots, \frac{1}{\sigma_r}, 0, \dots, 0\right) \in \mathbb{R}^{n \times m}$$

and $\text{rank}(B) = r$. It is the unique minimal Frobenius ^e norm solution to the problem

$$\min_{X \in \mathbb{R}^{n \times m}} \|BX - I_m\|_F$$

If $\text{rank}(B) = n$, then $B^* = (B^T B)^{-1} B^T$, while if $m = n = \text{rank}(B)$, then $B^* = B^{-1}$. Typically, B^* is defined to be the unique matrix $X \in \mathbb{R}^{n \times m}$ that satisfies the four *Moore-Penrose conditions*:

$$\begin{aligned} BXB &= B \\ XBX &= X \\ (BX)^T &= BX \\ (XB)^T &= XB \end{aligned}$$

These conditions amount to the requirement that BB^* and B^*B be orthogonal projections onto $\text{range}(B)$ and $\text{range}(B^T)$ respectively^f.

Wright [141] points out that the existence of linearly dependent constraint gradients can interfere with the super-linear convergence of the sequential quadratic programming problem (SQP) and provides a stabilised algorithm for which super-linear convergence is still possible. Given a set of active constraints $\mathcal{A}(x) \subset \mathcal{K}$ at a point x and the complement $\mathcal{N}(x) = \mathcal{K} \setminus \mathcal{A}(x)$, Wright defines $g_{\mathcal{A}}(x) = \{g_i(x) \mid i \in \mathcal{A}(x)\}$, $g_{\mathcal{N}}(x) = \{g_i(x) \mid i \in \mathcal{N}(x)\}$, $\lambda_{\mathcal{A}}(x) = \{\lambda_i(x) \mid i \in \mathcal{A}(x)\}$, $\lambda_{\mathcal{N}}(x) = \{\lambda_i(x) \mid i \in \mathcal{N}(x)\}$. Wright considers the usual SQP problem and makes the following assumptions

1. a primal-dual solution point $(\tilde{x}, \tilde{\lambda})$ exists

^e*Golub and Van Loan* [38, Section 2.3.1, Section 2.2.1] define the Frobenius norm (also called the Euclidean norm) of a matrix A as

$$\|A\|_F = \sqrt{\sum_{i=1}^m \sum_{j=1}^n |a_{ij}|^2}$$

and the set of vector norms

$$\begin{aligned} \|x\|_p &= (|x_1|^p + \dots + |x_n|^p)^{\frac{1}{p}} \quad p \geq 1 \\ \|x\|_\infty &= \max_{1 \leq i \leq n} |x_i| \end{aligned}$$

$\|x\|$ is assumed to mean $\|x\|_2$.

On the other hand, the Octave manual defines the Frobenius norm of a matrix as

$$\text{norm}(A, "fro") = \text{sqrt}\left(\text{sum}\left(\text{diag}\left(A^T A\right)\right)\right)$$

^f*Golub and Van Loan* [38, Section 2.1.2] define the *range* and *null space* or *kernel* of B as

$$\begin{aligned} \text{range}(B) &= \{y \in \mathbb{R}^n \mid y = Bx, x \in \mathbb{R}^n\} \\ \text{null}(A) &= \{x \in \mathbb{R}^n \mid Bx = 0\} \end{aligned}$$

If $B = [b_1, \dots, b_n]$ is a column vector partitioning then the *span* of B is the set of all linear combinations of those column vectors

$$\text{span}\{b_1, \dots, b_n\} = \left\{ \sum_{j=1}^n \beta_j b_j \mid \beta_j \in \mathbb{R} \right\}$$

Consequently, given the SVD of a matrix B with $\text{rank}(B) = r$

$$\begin{aligned} \text{null}(B) &= \text{span}\{v_{r+1}, \dots, v_n\} \\ \text{range}(B) &= \text{span}\{u_1, \dots, u_r\} \end{aligned}$$

2. for at least one of the active constraints, $\tilde{\lambda}_i > 0$ where $i \in \mathcal{A}(\tilde{x})$
3. $\tilde{\lambda}_i = 0 \forall i \in \mathcal{N}(\tilde{x})$
4. there exists a $\sigma > 0$ such that $w^T \nabla_{xx} \mathcal{L}(\tilde{x}, \tilde{\lambda}) w \geq \sigma \|w\|^2$ for all $\tilde{\lambda}$ such that $(\tilde{x}, \tilde{\lambda})$ satisfies the *Karush-Kuhn-Tucker* conditions and all $w \in \text{null}(\nabla g_{\mathcal{A}}(\tilde{x}))$
5. $\nabla g_{\mathcal{A}}(\tilde{x}) d < 0$ for some $d \in \mathbb{R}^n$

The latter assumption (known as the *Mangasarian-Fromovitz* constraint qualification) is weaker than the assumption that the matrix of constraint gradients has full column rank. *Wright* [141] considers the linearised SQP method described in Section I.5. He points out that the Lagrange multipliers $\lambda_{\mathcal{A}}$ may not be uniquely determined if the Jacobian $\nabla_x g_{\mathcal{A}}(x)$ is rank deficient. Consequently, the Hessian $\nabla_{xx} \mathcal{L}(x, \lambda_{\mathcal{A}})$ may not be uniquely defined at the next SQP iteration. He proposes a stabilised version of the SQP algorithm

$$\min_x \max_{\lambda_{\mathcal{A}} \geq 0} \langle \nabla f(\bar{x}), x - \bar{x} \rangle - \langle \lambda_{\mathcal{A}}, g(\bar{x}) + \nabla_x^T g(\bar{x})(x - \bar{x}) \rangle + \frac{1}{2} \langle x - \bar{x}, [\nabla_{xx}^2 \mathcal{L}(\bar{x}, \bar{\lambda}_{\mathcal{A}})](x - \bar{x}) \rangle - \frac{1}{2}\nu \|\lambda_{\mathcal{A}} - \bar{\lambda}_{\mathcal{A}}\|^2$$

where ν is defined as

$$\nu(x, \lambda_{\mathcal{A}}) = \|(\nabla_x \mathcal{L}(x, \lambda_{\mathcal{A}}), g_{\mathcal{A}}(x), \langle \lambda_{\mathcal{A}}, g_{\mathcal{A}}(x) \rangle)\|$$

The optimality conditions for a candidate solution $(\tilde{x}, \tilde{\lambda}_{\mathcal{A}})$ are likewise similar

$$\begin{aligned} \nabla_x f(\bar{x}) - \nabla g_{\mathcal{A}}(\bar{x}) \tilde{\lambda}_{\mathcal{A}} + \nabla_{xx} \mathcal{L}(\bar{x}, \bar{\lambda}_{\mathcal{A}})(\tilde{x} - \bar{x}) &= 0 \\ g_{\mathcal{A}}(\bar{x}) + \nabla_x^T g_{\mathcal{A}}(\bar{x})(\tilde{x} - \bar{x}) - \nu(\tilde{\lambda}_{\mathcal{A}} - \bar{\lambda}_{\mathcal{A}}) &\geq 0 \\ \tilde{\lambda}_{\mathcal{A}} &\geq 0 \\ \langle \tilde{\lambda}_{\mathcal{A}}, g_{\mathcal{A}}(\bar{x}) + \nabla g_{\mathcal{A}}^T(\bar{x})(\tilde{x} - \bar{x}) - \nu(\tilde{\lambda}_{\mathcal{A}} - \bar{\lambda}_{\mathcal{A}}) \rangle &= 0 \end{aligned}$$

Wright shows that for $(\bar{x}, \bar{\lambda}_{\mathcal{A}})$ sufficiently close to a primal-dual solution $(x, \lambda_{\mathcal{A}})$ there is a unique solution $(\tilde{x}, \tilde{\lambda}_{\mathcal{A}})$ for which $\|(\tilde{x} - \bar{x}, \tilde{\lambda}_{\mathcal{A}} - \bar{\lambda}_{\mathcal{A}})\| = \mathcal{O}(\nu)$. This solution satisfies the following linear system

$$\begin{bmatrix} \nabla_{xx} \mathcal{L}(\bar{x}, \bar{\lambda}_{\mathcal{A}}) & -\nabla_x g_{\mathcal{A}}(\bar{x}) \\ -\nabla_x g_{\mathcal{A}}^T(\bar{x}) & \nu I \end{bmatrix} \begin{bmatrix} x - \bar{x} \\ \lambda_{\mathcal{A}} - \bar{\lambda}_{\mathcal{A}} \end{bmatrix} = \begin{bmatrix} -(\nabla_x f(\bar{x}) - \nabla_x g_{\mathcal{A}}(\bar{x}) \bar{\lambda}_{\mathcal{A}}) \\ g_{\mathcal{A}}(\bar{x}) \\ \lambda_{\mathcal{N}} = 0 \end{bmatrix}$$

I.7.4 Bertsekas' modification to the Hessian

Bertsekas [26, p. 461] describes a modification to the Hessian that can ensure that the Hessian is positive definite and invertible. From the usual Newton system

$$\begin{aligned} \mathcal{H}_k d^k - \mathcal{B}_k \lambda^{k+1} &= -\nabla_x f(x^k) \\ -\mathcal{B}_k^T d^k &= g(x^k) \end{aligned}$$

define a new matrix:

$$\bar{\mathcal{H}}_k = \mathcal{H}_k + c^k \mathcal{B}_k \mathcal{B}_k^T$$

where the scalar, c^k , is chosen so that $\bar{\mathcal{H}}_k$ is positive definite. *Bertsekas* points out that

$$d^k \mathcal{B}_k \mathcal{B}_k^T d^k = \|g(x^k)\|^2$$

is a constant for *equality* constraints. Consequently, the modified optimisation problem

$$\begin{aligned} \text{minimise} \quad & \nabla_x f(x^k) d^k + \frac{1}{2} d^k \mathcal{B}_k \mathcal{B}_k^T d^k \\ \text{subject to} \quad & -\mathcal{B}_k^T d^k = g(x^k) \end{aligned}$$

has a larger minimum value but the location of that minimum is unchanged.

Given the scalar, c^k , write:

$$c^k \mathcal{B}_k \mathcal{B}_k^T d^k = -c^k \mathcal{B}_k g(x^k)$$

Adding:

$$(\mathcal{H}_k + c^k \mathcal{B}_k \mathcal{B}_k^T) d^k - \mathcal{B}_k \lambda^{k+1} = -[\nabla_x f(x^k) + c^k \mathcal{B}_k g(x^k)]$$

As in Section I.6:

$$\begin{aligned}\lambda^{k+1} &= -\left(\mathcal{B}_k^T (\mathcal{H}_k + c^k \mathcal{B}_k \mathcal{B}_k^T)^{-1} \mathcal{B}_k\right)^{-1} \left[g(x^k) - \mathcal{B}_k^T (\mathcal{H}_k + c^k \mathcal{B}_k \mathcal{B}_k^T)^{-1} (\nabla_x f(x^k) + c^k \mathcal{B}_k g(x^k))\right] \\ d^k &= -(\mathcal{H}_k + c^k \mathcal{B}_k \mathcal{B}_k^T)^{-1} [(\nabla_x f(x^k) + c^k \mathcal{B}_k g(x^k)) - \mathcal{B}_k \lambda^{k+1}]\end{aligned}$$

I.8 Penalty and barrier methods

From *Bertsekas* [26, Section 4.2], “The basic idea in penalty methods is to eliminate some or all of the constraints and add to the cost function a penalty term that prescribes a high cost to infeasible points.” Barrier functions are penalty functions that approach infinity as the constrained variable approaches the constraint. Clearly a barrier function requires that a feasible initial point is known.

I.8.1 Penalty functions

In the unconstrained case τ^k is found by a line search that minimises the objective function $f(x)$ along the ray $x^k + \tau d^k$ over $\tau \geq 0$. *Ruszczynski* [8, p.329] suggests that when there are constraints on x we use the *penalty function*

$$\Psi_\varrho(x) \triangleq f(x) + \varrho \left[\sum_{i=1}^p |h_i(x)| - \sum_{i=1}^m \min(0, g_i(x)) \right]$$

and states that a local minimum of the objective function is also a local minimum of $\Psi_\varrho(x)$, provided that the penalty coefficient ϱ is larger than the “max” norm of the Lagrange multipliers $(\hat{\lambda}, \hat{\mu})$ at the solution. Similarly, *Powell* [88, p.151] suggests using the penalty function

$$\Psi(x) \triangleq f(x) - \left[\sum_{i=1}^m \Omega_i \min(0, g_i(x)) + \sum_{i=1}^p \Upsilon_i |h_i(x)| \right]$$

and requiring that τ^k satisfies

$$\Psi(x^k + \tau^k d^k, \Omega, \Upsilon) \leq \Psi(x^k, \Omega, \Upsilon)$$

Υ_i and Ω_i are defined below. This condition can be fulfilled if the function

$$\Phi(\tau^k) = \Psi(x^k + \tau^k d^k, \Omega, \Upsilon)$$

decreases initially when τ^k is made positive. *Powell* [88] asserts that this happens if \mathcal{W}_k is positive definite and if

$$\begin{aligned}\Omega_i &\geq |\lambda_i| \quad i = 1, \dots, m \\ \Upsilon_i &\geq |\mu_i| \quad i = 1, \dots, p\end{aligned}$$

Powell [88, p.151] suggests $\Omega_i = |\lambda_i|$ for the first iteration and subsequently

$$\Omega_i = \max \left(|\lambda_i|, \frac{1}{2} [\bar{\Omega}_i + |\lambda_i|] \right)$$

where $\bar{\Omega}_i$ is the value of Ω_i used on the previous iteration. Similarly for Υ_i . The line-search procedure given by *Powell* [88, p.152] is obscure but it appears to be a variation of the “two-slope” test that is also described by *Ruszczynski* [8, p. 216] and *Bertsekas* [26, p. 28]. The test assumes that $\Phi'(0) < 0$. *Powell* [88, p.152] suggests that the line-search terminate when

$$\Phi(\hat{\tau}_k) \leq \Phi(0) + 0.1\tau^k \Phi'(0)$$

Bertsekas [26, p. 405], describes use of a quadratic penalty function with inequality constraints. The inequality constraints are converted to equality constraints by the addition of slack variables, z_i , giving the SQP problem

$$\begin{aligned} & \text{minimise} && f(x) \\ & \text{subject to} && h_i(x) = 0 \\ & && g_i(x) - z_i^2 = 0 \end{aligned}$$

The Quadratic Penalty Function method (Bertsekas [26, Section 4.2.1] gives a series of unconstrained minimisations of the form

$$\min_{x,z} \bar{\mathcal{L}}_{c^k}(x, z, \mu^k, \lambda^k) = f(x) + \left\{ \frac{c^k}{2} \|h(x)\|^2 - (\mu^k)^T h(x) \right\} + \sum_{i=1}^m \left\{ \frac{c^k}{2} |g_i(x) - z_i^2|^2 - \lambda_i^k (g_i(x) - z_i^2) \right\}$$

where $c^k < c^{k+1}$ and $c^k \rightarrow \infty$. Minimising the sum with respect to z is equivalent to

$$\mathcal{L}_{c^k}(x, v, \mu^k, \lambda^k) = f(x) + \left\{ \frac{c^k}{2} \|h(x)\|^2 - (\mu^k)^T h(x) \right\} + \min_{v_i \geq 0} \sum_{i=1}^m \left\{ \frac{c^k}{2} |g_i(x) - v_i|^2 - \lambda_i^k (g_i(x) - v_i) \right\}$$

If the constrained minimum of the second term is at $v_i^* = \max\{0, \bar{v}_i\}$ (where $\bar{v}_i \geq 0$ is the unconstrained minimum at which $\lambda_i + c^k(g_i(x) - \bar{v}_i)$ is zero) then

$$v_i^* = \max \left\{ 0, g_i(x) + \frac{\lambda_i^k}{c^k} \right\}$$

and

$$\begin{aligned} g_i(x) - v_i^* &= \begin{cases} -\frac{\lambda_i^k}{c^k} & g_i(x) > -\frac{\lambda_i^k}{c^k} \\ g_i(x) & g_i(x) \leq -\frac{\lambda_i^k}{c^k} \end{cases} \\ &= \min \left(g_i(x), -\frac{\lambda_i^k}{c^k} \right) \end{aligned}$$

The Lagrangian summation term becomes

$$\sum_{i=1}^m \lambda_i^k \min \left(g_i(x), -\frac{\lambda_i^k}{c^k} \right) + \frac{c^k}{2} \left| \min \left(g_i(x), -\frac{\lambda_i^k}{c^k} \right) \right|^2 = \begin{cases} \frac{1}{2c^k} \sum_{i=1}^m \left[(\lambda_i^k + c^k g_i(x))^2 - (\lambda_i^k)^2 \right] & g_i(x) \leq -\frac{\lambda_i^k}{c^k} \\ -\frac{1}{2c^k} \sum_{i=1}^m (\lambda_i^k)^2 & g_i(x) > -\frac{\lambda_i^k}{c^k} \end{cases}$$

Substituting into the Lagrangian

$$\mathcal{L}_{c^k}(x, \mu^k, \lambda^k) = f(x) + \left\{ \frac{c^k}{2} \|h(x)\|^2 - (\mu^k)^T h(x) \right\} + \frac{1}{2c^k} \sum_{i=1}^m \left\{ \min [0, (\lambda_i^k + c^k g_i(x))]^2 - \lambda_i^k \right\}$$

The penalty term for the inequality constraints is continuously differentiable in x if $g_i(x)$ is continuously differentiable. The optimisation problem is now unconstrained minimisation of \mathcal{L}_{c^k} with updating of the Lagrange multipliers by

$$\lambda^{k+1} = \min(0, \lambda^k + c^k g(x))$$

Unfortunately, difficulties arise because the Hessian matrix of \mathcal{L}_{c^k} is discontinuous at the x for which $g_i(x) = -\frac{\lambda_i^k}{c^k}$.

An alternative augmented Lagrangian function that does have a continuous Hessian adds an exponential penalty function

$$\psi(t) = e^{-t} - 1$$

The constrained optimisation problem becomes unconstrained optimisation of the following Lagrangian (for inequality constraints only)

$$\mathcal{L}_{c^k}(x, \lambda^k) = f(x) + \sum_{i=1}^m \frac{\lambda_i^k}{c_j^k} \psi(c_j^k g_j(x))$$

with gradient

$$\nabla \mathcal{L}_{c^k}(x, \lambda^k) = \nabla f(x) - \sum_{i=1}^m \lambda_i^k g(x) \exp(-c_j^k g_j(x))$$

The $\{c_j^k\}$ are a positive penalty parameter sequence for each j . The λ^k are updated by

$$\lambda^{k+1} = \lambda^k \exp(c^k g(x))$$

Two implementation details

- to avoid overflow $\psi(t)$ should be defined as the exponential $e^{-t} - 1$ only for the interval in which the exponential is within the floating point range
- the penalty parameter for each constraint should depend on the corresponding multiplier by

$$c_j^k = \frac{w^k}{\lambda_j^k}$$

where $\{w^k\}$ is a positive sequence with $w^k \leq w^{k+1}$

I.8.2 Barrier functions

Bertsekas [26, Section 4.1], describes adding a so-called *barrier* function, $B(x)$, to the cost function. This function is continuous and goes to ∞ as any one of the constraints approaches 0 from positive values. Clearly, the barrier function is only defined at iterates, x^k , that satisfy the constraints

$$S = \{x \in X \mid g_j(x) \geq 0, j = 1, \dots, m\}$$

The two most common barrier functions are

$$\begin{aligned} B(x) &= - \sum_{i=1}^m \ln \{g_i(x)\} \\ B(x) &= \sum_{i=0}^m \frac{1}{g_i(x)} \end{aligned}$$

The barrier method consists of finding

$$x^k \in \arg \min_{x \in S} \{f(x) + \epsilon^k B(x), k = 0, 1, \dots\}$$

where the sequence $\{\epsilon^k\}$ is defined by

$$0 < \epsilon^{k+1} < \epsilon^k \quad k = 0, 1, \dots \quad \epsilon^k \rightarrow 0$$

I.9 Finding the step size

The coefficient solution space for the IIR filter design problem is highly non-linear and has many local minima. At each iteration of the SQP method the maximum step-size to the next estimate must maintain the positive semi-definiteness of the Hessian (or its approximation) but at the same time be large enough that solution approaches a minimum efficiently.

I.9.1 Line search with the Golden-Section

The *Golden Section* (see Ruszczynski [8, p.213] and Bertsekas [26, Appendix C.3]) is a simple means of generating the sequence of intervals required for line-search on a *convex* function. First, given two endpoint points $\alpha < \delta$, construct a sequence of four points

$$\alpha < \beta < \gamma < \delta$$

with

$$\begin{aligned} \beta &= \alpha + (1 - q)(\delta - \alpha) \\ \gamma &= \delta - (1 - q)(\delta - \alpha) \end{aligned}$$

where

$$\begin{aligned} q &= \frac{-1 + \sqrt{5}}{2} \\ 1 - q &= q^2 \end{aligned}$$

Note that

$$\begin{aligned}\frac{\beta - \alpha}{\delta - \alpha} &= 1 - q \\ \frac{\gamma - \alpha}{\delta - \alpha} &= q \\ \frac{\gamma - \beta}{\delta - \beta} &= 1 - q \\ &\quad \text{etc.}\end{aligned}$$

At each iteration select a new endpoint based on the function values at each point. The Octave function *goldensection.m* shows an implementation.

A quicker search method makes use of the fact that the gradient $\Phi'(0)$ is known and is negative [8, p.215]. First, search for a point $\beta > 0$ such that $\Phi(\beta) \geq \Phi(0)$, then quadratic interpolation gives

$$\tau^k = \frac{-\Phi'(0)\beta^2}{2[\Phi(\beta) - \Phi(0) - \Phi'(0)\beta]}$$

Since $\Phi(\beta) \geq \Phi(0)$, we have $0 < \tau^k \leq \frac{\beta}{2}$. If we still have $\Phi(\tau) > \Phi(0)$, then we replace β with τ^k and repeat the above interpolation. If $\Phi(\tau) < \Phi(0)$, then we have three points, with the best one in the middle, and we can apply a Golden Section search.

Alternatively, interpolate $\Phi(x)$. Given $\alpha_k < \tau^k < \beta_k$ such that $\Phi(\alpha_k) > \Phi(\tau^k) < \Phi(\beta_k)$ then a second-order estimate of the minimum is

$$\gamma_k = \frac{\Phi(\alpha_k)[\beta_k^2 - (\tau^k)^2] + \Phi(\tau^k)[\alpha_k^2 - \beta_k^2] + \Phi(\beta_k)[(\tau^k)^2 - \alpha_k^2]}{2(\Phi(\alpha_k)[\beta_k - \tau^k] + \Phi(\tau^k)[\alpha_k - \beta_k] + \Phi(\beta_k)[\tau^k - \alpha_k])}$$

The initial three points can be found by scanning the values $\Phi(0), \Phi(\tau_0), \dots$ or $\Phi(0), \Phi(-\tau_0), \dots$ depending on whether $\Phi(\tau_0) < \Phi(0)$.

I.9.2 Inexact step-size selection

The previous sub-section describes a brute-force search for the best step-size. Bertsekas [26, p. 28] describes selection rules for finding a step-size that is neither too large nor too small but “good enough”. This approach usually requires far fewer function evaluations than an “exact” line search for a problem with a convex, differentiable objective function.

The inexact step-size rules are motivated by the solution to the locally convergent system of equations shown in Equation I.2. Ignoring the constraints:

$$\mathcal{H}_k d^k = -\nabla_x f(x^k)$$

Since we approximate \mathcal{H}_k by a positive-definite matrix, \mathcal{W}_k :

$$\langle \nabla_x f(x^k), d^k \rangle = -\langle \nabla_x f(x^k), \mathcal{W}_k^{-1} \nabla_x f(x^k) \rangle < 0$$

and d^k is a descent direction.

Bertsekas [26, p. 29], recommends the use of the *Armijo* rule. Given an initial step size $\sigma > 0$ and $\beta \in (0, 1)$, choose τ^k to be the largest in $\{\sigma, \sigma\beta, \sigma\beta^2, \dots\}$ so that

$$f(x^k + \tau^k d^k) \leq f(x^k) + c_1 \tau^k \langle \nabla_x f(x^k), d^k \rangle \tag{W1}$$

The Armijo rule reduces the step size geometrically. An implementation of line search using the *Armijo* rule is shown in Algorithm I.3.

Kim et al. [98] claim improved efficiency with the following modification to the *Armijo* rule:

$$f(x^k + \tau^k d^k) \leq f(x^k) + c_1 \tau^k \left[\langle \nabla_x f(x^k), d^k \rangle + \frac{1}{2} \tau^k \langle d^k, \mathcal{W}_k d^k \rangle \right] \tag{I.4}$$

Algorithm I.3 Line search using the Armijo rule

```

 $\beta \in [0.1, 0.5]$ 
 $\sigma \in [10^{-5}, 10^{-1}]$ 
while  $f(x^k) - f(x^k + \beta^m d^k) \geq -c_1 \sigma \beta^m \langle \nabla_x f(x^k), d^k \rangle$  do
     $m = m + 1$ 
end while
 $\tau = \sigma \beta^m$ 

```

To rule out unacceptably short steps, the *Wolfe* step-size rules add the following to the *Armijo* rule (or *W1*):

$$\langle \nabla_x f(x^k + \tau^k d^k), d^k \rangle \geq c_2 \langle \nabla_x f(x^k), d^k \rangle \quad (\text{W2})$$

where $0 < c_1 < c_2 < 1$. Common choices for the Newton or quasi-Newton methods are $c_1 = 10^{-4}$ and $c_2 = 0.9$. The second *Wolfe* condition may be strengthened to

$$|\langle \nabla_x f(x^k + \tau^k d^k), d^k \rangle| \leq |c_2 \langle \nabla_x f(x^k), d^k \rangle| \quad (\text{I.5})$$

This stronger *Wolfe* condition does not allow the gradient to be too positive, excluding points that are far from the minimum. Christianson [16] gives Algorithm I.4 for line search using the Wolfe conditions.

Algorithm I.4 Line search using Wolfe conditions

```

 $R = 1, r = 0.5, \tau = 1, a = 0, b = \infty$ 
while  $a \neq b$  do
    if  $W1(\tau)$  then
         $a = \tau$ 
    else
         $b = \tau$ 
    end if
    if  $W1(\tau) \wedge W2(\tau)$  then
         $b = \tau$ 
    else
        if  $b = \infty$  then
             $\tau = \max(\tau, Ra)$ 
        else
             $\tau = \max((1-r)a + rb, \min(\tau, ra + (1-r)b))$ 
        end if
    end if
end while

```

The *Goldstein* conditions for step-size selection are similar to the *Wolfe* conditions:

$$f(x^k + \tau^k d^k) < f(x^k) + c_1 \tau^k \langle \nabla_x f(x^k), d^k \rangle \quad (\text{G1})$$

$$f(x^k + \tau^k d^k) > f(x^k) + c_2 \tau^k \langle \nabla_x f(x^k), d^k \rangle \quad (\text{G2})$$

where $0 < c_1 < c_2 < 1$. Usually $c_1 < 0.5$ and $c_2 = 1 - c_1$. Christianson gives Algorithm I.5 for line search using the *Goldstein* conditions. The first iteration in Algorithm I.5 must terminate because $f(x)$ is differentiable at x^k . The second iteration must

Algorithm I.5 Line search using the Goldstein conditions

```

 $\tau = 1, R = 2$ 
while  $\neg G1(\tau)$  do
     $\tau = \frac{\tau}{R}$ 
end while
while  $\neg G2(\tau)$  do
     $\tau = \tau R$ 
end while

```

terminate because $f(x)$ is bounded below. Note that the two while loops can be placed in either order, and that at most one of them will ever be performed.

I.9.3 Lanczos step-size selection

Toh [74] describes estimation of the step-size by the *Lanczos* iteration for finding the eigenvalues of a matrix. The updated approximation to the Hessian is expressed as:

$$\mathcal{W}_{k+1} = \mathcal{W}_k + \rho_k \Delta \mathcal{W}_k$$

Since \mathcal{W}_k is symmetric and positive-definite, it has a Cholesky factorisation $\mathcal{W}_k = L_k^T L_k$. Let

$$\mathcal{B}_k = -L_k^{-T} \Delta \mathcal{W}_k L_k^{-1}$$

then the condition that $\mathcal{W}_{k+1} \succeq 0$ is equivalent to $I - \rho_k \mathcal{B}_k \succeq 0$. In other words

$$\max \rho_k = \begin{cases} \frac{1}{\lambda_1} & \lambda_1 > 0 \\ \infty & \text{otherwise} \end{cases}$$

where λ_1 is the maximum eigenvalue of \mathcal{B}_k and ρ_k provides an upper bound on the corresponding step-size $\tau^k d^k$. Toh suggests that the required computation can be reduced by finding λ_1 with the *Lanczos* iteration method. Given a symmetric matrix, $A \in \mathbb{R}^{N \times N}$, the *Lanczos* method generates a sequence of tridiagonal matrices $T_k \in \mathbb{R}^{k \times k}$ having the property that the extremal eigenvalues of T_k are progressively better estimates of the extremal eigenvalues of A . Golub and van Loan describe efficient methods for finding the eigenvalues of a symmetric tridiagonal matrix [38, Section 8.5] and have an extensive discussion of *Lanczos* methods [38, Chapter 9].

I.10 Initial solution with the Goldfarb-Idnani algorithm

Goldfarb and Idnani [25] observe that the origin in the space of dual variables (ie: Lagrange multipliers) is always a feasible solution of the dual problem. In Algorithm I.6 I reproduce their dual algorithm for solving the tangent quadratic problem with linear constraints.

Some explanation of the notation is required. The problem statement is:

$$\begin{aligned} \text{minimise} \quad & f(x) = a^T x + \frac{1}{2} x^T H x \\ \text{subject to} \quad & g(x) \equiv G^T x - b \geq 0 \end{aligned}$$

This is equivalent to the linearised optimisation problem defined in Section I.5. The *Goldfarb-Idnani* dual algorithm commences with the unconstrained minimum $x = -H^{-1}a$ and adds constraints to the active constraint set, \mathcal{A} , having cardinality q , until all constraints are satisfied. In the following the set of all constraints is denoted \mathcal{K} , \mathcal{A}^+ denotes $\mathcal{A} \cup \{p\}$ where $p \in \mathcal{K} \setminus \mathcal{A}$ and \mathcal{A}^- represents the subset of \mathcal{A} that contains one fewer element than \mathcal{A} . A *subproblem* $P(\mathcal{A})$ is defined to be the quadratic programming problem subject only to the subset of the constraints indexed by $\mathcal{A} \subset \mathcal{K}$. If the solution x of a subproblem $P(\mathcal{J})$ lies on a linearly independent set of constraints indexed by $\mathcal{A} \subseteq \mathcal{J}$ then (x, \mathcal{A}) is called a *solution-pair* or *S-pair*. B , B^+ and B^- represent the matrices of constraint gradients corresponding to \mathcal{A} , \mathcal{A}^+ and \mathcal{A}^- . n^+ represents the gradient vector added to B to form B^+ . Similarly for n^- . I_k denotes the $k \times k$ identity matrix and e_j represents the j th column of I_k .

When the constraint gradients (columns of B) are linearly independent one can define the operators

$$\begin{aligned} B^* &= (B^T H^{-1} B)^{-1} B^T H^{-1} \\ E &= H^{-1} (I - BB^*) \end{aligned}$$

where B^* is the *pseudo-inverse* or *Moore-Penrose generalised inverse* of B . E is a reduced inverse Hessian operator for the quadratic $f(x)$ subject to the active set of constraints. In particular, as in [25], if \hat{x} is a point in the $(n-q)$ dimensional manifold $\mathcal{M} = \{x \in \mathbb{R}^n \mid n_i^T x = b_i, i \in \mathcal{A}\}$ and $\nabla_x f(\hat{x}) = H\hat{x} + a$ is the gradient of $f(x)$ at \hat{x} then the minimum of $f(x)$ over \mathcal{M} is attained at $\tilde{x} = \hat{x} - E\nabla_x f(\hat{x})$. For \tilde{x} to be the optimal solution for the subproblem $P(\mathcal{A})$

$$\nabla_x f(\tilde{x}) = B\lambda(\tilde{x})$$

where the vector of Lagrange multipliers $\lambda(\tilde{x}) \geq 0$. Multiplying both sides by B^* gives

$$\lambda(\tilde{x}) \equiv B^* \nabla_x f(\tilde{x}) \geq 0$$

Algorithm I.6 The Goldfarb-Idnani dual algorithm [25]

0. Find the unconstrained minimum of $f(x)$, then:

Set $x \leftarrow H^{-1}a$, $f \leftarrow \frac{1}{2}a^T x$, $E \leftarrow H^{-1}$, $\mathcal{A} \leftarrow \emptyset$, $q \leftarrow 0$

1. Choose the most violated constraint, if any:

Compute $g_j(x)$, for all $j \in \mathcal{K} \setminus \mathcal{A}$.

If $\mathcal{V} = \{j \in \mathcal{K} \setminus \mathcal{A} \mid g_j(x) < 0\} = \emptyset$ then **stop**, the current solution x is both feasible and optimal.

Otherwise, choose $p \in \mathcal{V}$ and set $n^+ \leftarrow n_p$ and $\lambda^+ \leftarrow \begin{pmatrix} \lambda \\ 0 \end{pmatrix}$.

If $q = 0$ then set $\lambda^+ \leftarrow 0$.

Set $\mathcal{A}^+ = \mathcal{A} \cup \{p\}$.

2. Check for feasibility and determine a new solution pair:

(a) Determine the step direction:

Compute $d = En^+$ (the step direction in the primal space).

If $q > 0$ then $r = B^*n^+$ (the negative of the step direction in the dual space).

(b) Compute the step length:

i. Partial step length, τ_1 :

This is the maximum step in dual space without violating dual feasibility.

If $r \leq 0$ or $q = 0$ then set $\tau_1 \leftarrow \infty$.

Otherwise, set

$$\tau_1 \leftarrow \min_{r_j > 0, j=1,\dots,q} \left\{ \frac{\lambda_j^+(x)}{r_j} \right\} = \frac{\lambda_l^+(x)}{r_l}$$

In Step 2c below, element $k \in \mathcal{K}$ corresponds to the l -th element in \mathcal{A} .

ii. Full step length, τ_2 :

This is the minimum step in primal space such that the p -th constraint becomes feasible.

If $|d| = 0$ then set $\tau_2 \leftarrow \infty$.

Otherwise, set $\tau_2 \leftarrow -\frac{g_p(x)}{d^T n^+}$.

iii. Step length, τ :

Set $\tau \leftarrow \min(\tau_1, \tau_2)$

(c) Determine a new solution pair and take the step:

i. No step in primal or dual space:

If $\tau = \infty$ then **stop**. The sub-problem $P(\mathcal{A}^+)$ and hence the quadratic problem are infeasible.

ii. Step in dual space:

If $\tau_2 = \infty$, then set $\lambda^+ \leftarrow \lambda^+ + \tau \begin{pmatrix} -r \\ 1 \end{pmatrix}$, and drop constraint k ;

i.e. set $\mathcal{A} \leftarrow \mathcal{A} \setminus \{k\}$, $q \leftarrow q - 1$, update E and B^* , and go to Step 2a.

iii. Step in primal and dual space:

Set $x \leftarrow x + \tau d$, $f \leftarrow f + \tau d^T n^+ (\frac{1}{2}\tau + \lambda_{q+1}^+)$, $\lambda^+ \leftarrow \lambda^+ + \tau \begin{pmatrix} -r \\ 1 \end{pmatrix}$.

If $\tau = \tau_2$ (a full step) then set $\lambda \leftarrow \lambda^+$ and add constraint p ;

i.e. set $\mathcal{A} \leftarrow \mathcal{A} \cup \{p\}$, $q \leftarrow q + 1$, update E and B^* and go to Step 1.

If $\tau = \tau_1$ (partial step) then drop constraint k ;

i.e. set $\mathcal{A} \leftarrow \mathcal{A} \setminus \{k\}$, $q \leftarrow q - 1$, update E and B^* , and go to Step 2a.

Also multiplying by E gives

$$\begin{aligned} E\nabla f(\tilde{x}) &= H^{-1}(I - BB^*)B\lambda \\ &= H^{-1}(B - B)\lambda \\ &= 0 \end{aligned}$$

These conditions are necessary and sufficient for \tilde{x} to be the optimal solution to $P(\mathcal{A})$. In addition, the dual algorithm makes use of a set of, so-called, *infeasibility* multipliers

$$r = B^*n^+$$

Some properties of B^* and E :

$$\begin{aligned} Ew &= 0 \Leftrightarrow w = B\alpha \\ E &\text{ is positive semidefinite} \\ EWE &= E \\ B^*WE &= 0 \\ EE^+ &= E^+ \end{aligned}$$

When justifying Algorithm I.6, *Goldfarb and Idnani* [25, p. 7] first point out that for a given S-pair (x, \mathcal{A}) and a violated constraint p , if the columns of B^+ (ie: those of B and $n^+ = n_p$) are linearly independent, then

$$\begin{aligned} g_p(x) &< 0 \\ g_i(x) &= 0 \quad \forall i \in \mathcal{A} \\ E^+\nabla_x f(x) &= 0 \\ \lambda^+(x) &\triangleq (B^+)^*\nabla_x f(x) \geq 0 \end{aligned}$$

Definition 1: A triple (x, \mathcal{A}, p) consisting of a point x and a set of indices $\mathcal{A}^+ = \mathcal{A} \cup \{p\}$ where $p \in \mathcal{K} \setminus \mathcal{A}$ is said to be a V(violated)-triple if the columns of B^+ are linearly independent and the above conditions apply.

The point \hat{x} corresponding to the V-triple $(\hat{x}, \mathcal{A}, p)$ is the optimal solution to the subproblem obtained by replacing the constraint $g_p(x) \geq 0$ in $P(\mathcal{A}^+)$ by $g_p(x) \geq g_p(\hat{x})$ i.e. by a parallel constraint which passes through \hat{x} . Let x^* be the point on the manifold $\mathcal{M}^+ = \{x \in \mathbb{R}^n \mid n_i^T x = b_i, i \in \mathcal{A}^+\}$ at which $f(x)$ is minimized. The following lemma shows how to move to such a point from a point x corresponding to a V-triple (x, \mathcal{A}, p) .

Lemma 1: Let (x, \mathcal{A}, p) be a V-triple and consider points of the form $\tilde{x} = x + \tau d$ where $d = En^+$. Then

$$E^+\nabla_x f(\tilde{x}) = 0 \tag{I.6}$$

$$g_i(\tilde{x}) = 0 \quad \forall i \in \mathcal{A} \tag{I.7}$$

$$\lambda^+(\tilde{x}) \triangleq (B^+)^*\nabla_x f(\tilde{x}) = \lambda^+(x) + \tau \begin{bmatrix} -r \\ 1 \end{bmatrix} \tag{I.8}$$

where $r = B^*n^+$ and $g_p(\tilde{x}) = g_p(x) + \tau d^T n^+$.

Proof: The lemma follows from the properties of the V-triple (x, \mathcal{A}, p) and

$$\nabla_x f(\tilde{x}) = \nabla_x f(x) + \tau Hd \tag{I.9}$$

where

$$\begin{aligned} Hd &= HEn^+ \\ &= (I - BB^*)n^+ \\ &= n^+ - Br \\ &= [B \quad n^+] \begin{bmatrix} -r \\ 1 \end{bmatrix} \\ &= B^+ \begin{bmatrix} -r \\ 1 \end{bmatrix} \end{aligned}$$

Recalling that $EB = H^{-1}(B - BB^*B) = 0$, the results follow from multiplying Equation I.9 on the left by E^+ and B^+ .

It follows from this lemma that the point $\tilde{x} = x + \tau_2 d$, where $\tau_2 = -\frac{g_p(x)}{d^T n^+}$, minimises the quadratic function $f(x)$ over \mathcal{M}^+ (since then $g_p(\tilde{x}) = 0$). If $\lambda^+(\tilde{x}) \geq 0$ as well, then \tilde{x} is an optimal solution to $P(\mathcal{A}^+)$ and $(\tilde{x}, \mathcal{A}^+)$ is an S-pair. If not, then Equation I.8 implies that there is a smallest value τ_1 of τ , $\tau_1 < \tau_2$, such that some component of $\lambda^+(\tilde{x}(\tau)) < 0$ for $\tau > \tau_1$. If the constraint, say $k \in \mathcal{A}$, corresponding to this component is dropped from the active set, then $(\tilde{x}(\tau_1), \mathcal{A}^-, p)$, where $\mathcal{A}^- = \mathcal{A} \setminus \{k\}$, is again a V-triple. These remarks are formalised by the following two theorems.

Theorem 1: Given a V-triple (x, \mathcal{A}, p) if \tilde{x} is defined as in Lemma 1 with $\tau = \min\{\tau_1, \tau_2\}$ where

$$\begin{aligned}\tau_1 &= \min \left\{ \min_{r_j > 0, 1 \leq j \leq q} \left\{ \frac{\lambda_j^+(x)}{r_j^+(x)} \right\}, \infty \right\} \\ \tau_2 &= -\frac{g_p(x)}{d^T n^+}\end{aligned}$$

then

$$\begin{aligned}g_P(\tilde{x}) &\geq g_p(x) \\ f(\tilde{x}) - f(x) &= \tau d^T n^+ \left(\frac{1}{2} \tau + \lambda_{q+1}^+(x) \right) \geq 0\end{aligned}$$

Moreover, if $\tau = \tau_1 = \frac{\lambda_l^+(x)}{r_l}$, then $(\tilde{x}, \mathcal{A} \setminus \{k\}, p)$ is a V-triple, where element $k \in \mathcal{K}$ corresponds to the l -th element in \mathcal{A} . Alternatively, if $\tau = \tau_2$, then $(\tilde{x}, \mathcal{A} \cup \{p\})$ is an S-pair.

Proof: Since (x, \mathcal{A}, p) is a V-triple,

$$d^T n^+ = n^{+T} E n^+ = n^{+T} E H E n^+ = d^T H d > 0$$

and $\tau \geq 0$. Hence, from Lemma 1, $g_P(\tilde{x}) \geq g_p(x)$. Also, from Taylor's theorem

$$f(\tilde{x}) - f(x) = \tau d^T \nabla_x f(x) + \frac{1}{2} \tau^2 d^T H d$$

Since $E^+ \nabla_x f(x) = 0$ implies that $\nabla_x f(x) = B^+ \lambda^+(x)$, it follows that $E \nabla_x f(x) = E n^+ \lambda_{q+1}^+(x)$ and

$$d^T \nabla_x f(x) = n^{+T} E \nabla_x f(x) = d^T n^+ \lambda_{q+1}^+(x) \geq 0$$

The result follows by substitution. Moreover, as long as $\tau > 0$, $f(\tilde{x}) > f(x)$. From the definition of τ and Lemma 1 it is evident that $E^+ \nabla_x f(\tilde{x}) = 0$, $g_i(\tilde{x}) = 0$, $i \in \mathcal{A}$ and $\lambda^+(\tilde{x}) \geq 0$. If $\tau = \tau_2$, then $g_p(\tilde{x}) = 0$ and $(x, \mathcal{A} \cup \{p\})$ is an S-pair. If $\tau = \tau_1 < \tau_2$, then $\lambda_l^+(\tilde{x}) = 0$ and $g_p(\tilde{x}) < 0$. Since $E^+ \nabla_x f(\tilde{x}) = 0$ and $\lambda_l^+(\tilde{x}) = 0$ we can write

$$\begin{aligned}\nabla_x f(\tilde{x}) &= B^+ \lambda^+(\tilde{x}) \\ &= \sum_{i \in \mathcal{A} \cup \{p\} \setminus \{k\}} \lambda_{j(i)}^+ n_i\end{aligned}$$

where i is the $j(i)$ -th index in $\mathcal{A}^+ = \mathcal{A} \cup \{p\}$. As the set of normals $\{n_i \mid i \in \mathcal{A} \cup \{p\} \setminus \{k\}\}$ is clearly linearly independent $(\tilde{x}, \mathcal{A} \setminus \{k\}, p)$ is a V-triple.

It follows from the above theorem that starting from a V-triple (x, \mathcal{A}, p) one can obtain an S-pair $(\tilde{x}, \tilde{\mathcal{A}} \cup \{p\})$ with $\tilde{\mathcal{A}} \subseteq \mathcal{A}$ and $f(\tilde{x}) > f(x)$ after at most q partial steps and one full step.

If n^+ is a linear combination of the columns of B at the start of Step 2, then (x, \mathcal{A}, p) is not a V-triple. In this case, either the subproblem $P(\mathcal{A} \cup \{p\})$ is infeasible or a constraint can be dropped from the active set \mathcal{A} so that (x, \mathcal{A}^-, p) is a V-triple. In the former case, the original quadratic problem must also be feasible, while in the latter case, one may proceed according to Theorem 1 to obtain a new S-pair with a higher function value.

Theorem 2: Let (x, \mathcal{A}) be an S-pair and p be an index of a constraint in $\mathcal{K} \setminus \mathcal{A}$ such that $n^+ \triangleq n_p = Br$ and $g_p(x) < 0$. If $r \leq 0$, then $P(\mathcal{A} \cup \{p\})$ is infeasible; otherwise the k -th component can be dropped from the active set, where k is determined by

$$\frac{\lambda_l(x)}{r_l} = \min_{r_j > 0, j=1,\dots,q} \left\{ \frac{\lambda_j(x)}{r_j} \right\}, \quad l = j(k)$$

to give $\mathcal{A}^- = \mathcal{A} \setminus \{k\}$ and the V-triple (x, \mathcal{A}^-, p) .

Proof: If there is a feasible solution $\tilde{x} = x + d$ satisfying the constraints $\mathcal{A} \cup \{p\}$, it is necessary that $n^{+T}d = r^T B^T d > 0$ and $B^T d \geq 0$ since $g_i(x) = 0$ for all $i \in \mathcal{A}$. But if $r \leq 0$, the two requirements in the theorem cannot be simultaneously satisfied; hence in this case $P(\mathcal{A} \cup \{p\})$ is infeasible. If a component of r is positive, it follows that $r_l > 0$ and that

$$n^+ = n_k r_l + \sum_{i \in \mathcal{A}^-} r_{j(i)} n_i$$

so

$$n_k = \frac{1}{r_l} \left[- \sum_{i \in \mathcal{A}^-} r_{j(i)} n_i + n^+ \right]$$

Since (x, \mathcal{A}) is an S-pair

$$\begin{aligned} \nabla_x f(x) &= \sum_{i \in \mathcal{A}^-} \lambda_{j(i)} n_i + \lambda_l n_k \\ &= \sum_{i \in \mathcal{A}^-} \left(\lambda_{j(i)} - \frac{\lambda_l}{r_l} r_{j(i)} \right) n_i + \frac{\lambda_l}{r_l} n^+ \end{aligned}$$

If we define $\hat{\mathcal{A}} = \mathcal{A}^- \cup \{p\}$, then it is clear that \hat{B} has full column rank, $\hat{E} \nabla_x f(x) = 0$ and

$$\begin{aligned} \hat{\lambda}(x) &= \hat{B}^* \nabla_x f(x) \\ &= \begin{cases} \lambda_{j(i)} - \frac{\lambda_l}{r_l} r_{j(i)} \geq 0 & i \in \mathcal{A}^- \\ \frac{\lambda_l}{r_l} \geq 0 & \end{cases} \end{aligned}$$

and hence that (x, \mathcal{A}^-, p) is a V-triple.

Goldfarb and Idnani [25, Section 4] base their implementation on the *Cholesky* factorisation

$$H = LL^T$$

of the positive definite symmetric Hessian matrix H and the *QR* factorisation

$$C = Q \begin{bmatrix} R \\ 0 \end{bmatrix} = [Q_1 \mid Q_2] \begin{bmatrix} R \\ 0 \end{bmatrix}$$

of the $(n \times q)$ matrix

$$C = L^{-1}B$$

where L is an $(n \times n)$ lower triangular matrix, R is a $(q \times q)$ upper triangular matrix and $Q = [Q_1 \mid Q_2]$ is a $(n \times n)$ orthogonal matrix partitioned so that Q_1 has q columns. By substitution,

$$\begin{aligned} B^* &= (B^T L^{-T} L^{-1} B)^{-1} B^T L^{-T} L^{-1} \\ &= (C^T C)^{-1} C^T L^{-1} \\ &= R^{-1} R^{-T} C^T L^{-1} \\ &= R^{-1} Q_1^T L^{-1} \\ &= R^{-1} J_1^T \end{aligned}$$

and

$$\begin{aligned} E &= L^{-T} L^{-1} - L^{-T} C (C^T C)^{-1} C^T L^{-1} \\ &= L^{-T} L^{-1} - L^{-T} C R^{-1} R^{-T} C^T L^{-1} \\ &= L^{-T} Q Q^T L^{-1} - L^{-T} Q_1 Q_1^T L^{-1} \\ &= L^{-T} Q_2 Q_2^T L^{-1} \\ &= J_2 J_2^T \end{aligned}$$

where

$$\begin{aligned} C^T C &= \begin{bmatrix} R^T & 0 \end{bmatrix} Q^T Q \begin{bmatrix} R \\ 0 \end{bmatrix} \\ &= R^T R \end{aligned}$$

and

$$\begin{aligned} CR^{-1} &= \begin{bmatrix} Q_1 & Q_2 \end{bmatrix} \begin{bmatrix} R \\ 0 \end{bmatrix} R^{-1} \\ &= Q_1 \end{aligned}$$

and

$$\begin{aligned} J &= \begin{bmatrix} J_1 & J_2 \end{bmatrix} \\ &= \begin{bmatrix} L^{-T} Q_1 & L^{-T} Q_2 \end{bmatrix} \\ &= L^{-T} Q \end{aligned}$$

In the dual algorithm the vectors $d = En^+$ and $r = B^*n^+$ are required. Compute the intermediate vector

$$\begin{aligned} v &= J^T n^+ \\ &= \begin{bmatrix} J_1^T \\ J_2^T \end{bmatrix} n^+ \\ &= \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} \end{aligned}$$

from which it follows that

$$d = J_2 v_2$$

and

$$r = R^{-1} v_1$$

Goldfarb and *Idnani* describe an efficient method for updating the factors J and R when a constraint is added or deleted.

I.11 Implementation examples

The archive distributed with this document contains Octave functions for the line-search and non-linear optimisation techniques described above.

The Octave file *sqp_common.m* contains the function to be optimised, constraints, gradients and the Hessian function:

$$\begin{aligned} \text{minimise } f(x) &= x_1^4 + x_2^4 + x_3^4 + x_1 x_2 + x_1 x_3 + x_2 x_3 + x_1 + x_2 + x_3 + 5 \\ \text{subject to } g(x) &= \begin{bmatrix} x_2 - 1; -x_1 - \sqrt{2}; -x_3 - 0.5 \end{bmatrix} \geq 0 \end{aligned}$$

linesearch_test.m implements unconstrained quasi-Newton optimisation of this function with step size found by line search with the Armijo, Goldstein, golden-section or quadratic-interpolation methods. Sample output of *linesearch_test.m* is:

Appendix J

Fourier transform of the Gaussian function

See *NIST Digital Library of Mathematical Functions* [36, Sections 7.2.1 and 1.14.1]

J.1 Preliminary results

The Gaussian function is e^{-t^2} .

J.1.1 Integral of the Gaussian function

Poisson introduced this method of integrating the Gaussian function:

$$\begin{aligned} \left[\int_{-\infty}^{\infty} e^{-t^2} dt \right]^2 &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{-x^2-y^2} dx dy \\ &= \int_0^{2\pi} \int_0^{\infty} e^{-r^2} r dr d\theta \\ &= 2\pi \int_0^{\infty} e^{-r^2} r dr \\ &= \pi \int_0^{\infty} e^{-s} ds \\ &= \pi [-e^{-s}]_0^{\infty} \\ &= \pi \end{aligned}$$

So:

$$\int_0^{\infty} e^{-t^2} dt = \frac{\sqrt{\pi}}{2}$$

J.1.2 Fourier transform of the derivative of a function

If $g(t)$ is absolutely integrable, bounded and differentiable on $(-\infty, \infty)$ then the Fourier transform, \mathcal{F} , of $g(t)$ is:

$$G(\omega) = \mathcal{F}g(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} g(t) e^{i\omega t} dt$$

and the inverse Fourier transform is:

$$g(t) = \mathcal{F}^{-1}G(\omega) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} G(\omega) e^{-i\omega t} d\omega$$

The Fourier transform of $\frac{dg(t)}{dt}$ is:

$$\begin{aligned}\mathcal{F} \frac{dg(t)}{dt} &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{dg(t)}{dt} e^{i\omega t} dt \\ &= \frac{1}{\sqrt{2\pi}} \left\{ [g(t) e^{i\omega t}]_{-\infty}^{\infty} - i\omega \int_{-\infty}^{\infty} g(t) e^{i\omega t} dt \right\} \\ &= -i\omega \mathcal{F}g(t)\end{aligned}$$

Similarly:

$$\begin{aligned}\mathcal{F}^{-1} \frac{dG(\omega)}{d\omega} &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{dG(\omega)}{d\omega} e^{-i\omega t} d\omega \\ &= \frac{1}{\sqrt{2\pi}} \left\{ [G(\omega) e^{-i\omega t}]_{-\infty}^{\infty} + it \int_{-\infty}^{\infty} G(\omega) e^{-i\omega t} dt \right\} \\ &= it \mathcal{F}^{-1} G(\omega)\end{aligned}$$

J.2 Derivation of the Fourier transform of the Gaussian function in the frequency domain

The Gaussian function in the frequency domain is:

$$G(\omega) = e^{-(\frac{\omega}{\alpha})^2}$$

Differentiating both sides:

$$\frac{dG(\omega)}{d\omega} = -\frac{2\omega}{\alpha^2} G(\omega)$$

Taking the Fourier transform of both sides:

$$itg(t) = -\frac{2i}{\alpha^2} \frac{dg(t)}{dt}$$

Rearranging and integrating both sides:

$$\begin{aligned}\int_0^t -\frac{\tau \alpha^2}{2} d\tau &= \int_0^t \frac{\frac{dg(\tau)}{d\tau}}{g(\tau)} d\tau \\ \ln g(t) - \ln g(0) &= -\left(\frac{t\alpha}{2}\right)^2 \\ g(t) &= g(0) e^{-\left(\frac{t\alpha}{2}\right)^2}\end{aligned}$$

where:

$$\begin{aligned}g(0) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-(\frac{\omega}{\alpha})^2} d\omega \\ &= \frac{2\alpha}{\sqrt{2\pi}} \int_0^{\infty} e^{-\omega^2} d\omega \\ &= \frac{\alpha}{\sqrt{2}}\end{aligned}$$

Appendix K

Design of IIR digital filter transfer functions

This chapter reviews methods of constructing IIR digital filter transfer functions. The first section reviews the analogue-to-digital transformation of s -plane Butterworth filters to the z -plane. The subsequent sections review methods of designing *equi-ripple* amplitude response IIR filters.

K.1 Design of Butterworth IIR filters

The Butterworth filter transfer function is described in many textbooks (for example, *Roberts and Mullis* [129, Chapter 6]). I have included it here to justify the implementation in *butter2pq.m*.

K.1.1 Continuous Time Second Order Butterworth Filter Prototypes

In the continuous time s -plane a low-pass Butterworth filter has, by definition, a squared magnitude frequency response of:

$$|\hat{H}(\omega)|^2 = \frac{1}{1 + \omega^{2n}}$$

The response with a cutoff angular frequency of ω_c is found by the s -plane transformation $s \rightarrow \frac{s}{\omega_c}$. The high-pass response is found by the s -plane transformation $s \rightarrow \frac{1}{s}$.

The $2n$ poles of the Butterworth squared magnitude response are evenly spaced around the unit circle in the s -plane. For stability, the filter realization as a cascade of second order sections uses the poles in the left-hand half plane, λ_k :

$$\begin{aligned}\lambda_k &= \omega_c e^{i\theta_k} \\ \theta_k &= \frac{\pi}{2} \left(1 + \frac{(2k-1)}{n} \right), \quad 1 \leq k \leq n\end{aligned}$$

For each conjugate pole pair the corresponding low-pass filter second-order section with unity DC gain has transfer function^a:

$$\begin{aligned}\hat{H}_k(s) &= \frac{\lambda_k \lambda_k^\dagger}{(s - \lambda_k)(s - \lambda_k^\dagger)} \\ &= \frac{\lambda_k \lambda_k^\dagger}{s^2 - (\lambda_k + \lambda_k^\dagger)s + \lambda_k \lambda_k^\dagger} \\ &= \frac{\omega_c^2}{s^2 - 2\omega_c \cos \theta_k s + \omega_c^2}\end{aligned}$$

If n is odd, there is a single real pole at $s = -\omega_c$, $k = \frac{n+1}{2}$, and the corresponding low-pass first-order section is:

$$\hat{H}_k(s) = \frac{\omega_c}{s + \omega_c}$$

^a \dagger denotes complex conjugate

The Butterworth high-pass filter with cut-off frequency ω_c is found with the s -plane transformation $\frac{s}{\omega_c} \rightarrow \frac{\omega_c}{s}$. The second order high-pass sections are:

$$\hat{H}_k(s) = \frac{s^2}{s^2 - 2\omega_c \cos \theta_k s + \omega_c^2}$$

and, if n is odd, the first order high-pass section is:

$$\hat{H}_k(s) = \frac{s}{\omega_c + s}$$

K.1.2 Design of discrete time filters with the bilinear transform

Various methods can be used to transform the analog prototype response to the discrete time domain. The “bi-linear” transform is:

$$H(z) = \hat{H}\left(\frac{1 - z^{-1}}{1 + z^{-1}}\right)$$

The bi-linear transform has the following properties:

- the s -plane $\imath\omega$ axis maps to the z -plane unit circle $z = e^{\imath\Omega T}$, where T is the sampling interval, and the s -plane left-half plane maps to the z -plane unit disc, $|z| \leq 1$.
- if the analog response is stable, the transformed response is also stable
- the zero frequency response is the same in both domains

The bilinear transform, $H(z)$ of the analog frequency response, $\hat{H}(s)$ is

$$H(e^{\imath\Omega T}) = \hat{H}\left(\imath \tan \frac{\Omega T}{2}\right)$$

The design frequencies of the analog prototype filter on the s -plane $\imath\omega$ axis must be “pre-warped” to the z -plane unit circle by the mapping $\tan \frac{\Omega T}{2} \rightarrow \omega$. In other words, the discrete-time filter behaves at frequency Ω in the same way that the continuous-time filter behaves at frequency $\omega = \tan \frac{\Omega T}{2}$. For example, if the desired cut-off frequency in the z -domain is $\Omega_c T = \frac{\pi}{2}$, then we choose the cutoff frequency of the s -plane prototype filter to be:

$$\omega_c = \tan \frac{\Omega_c T}{2} = \tan \frac{\pi}{4} = 1$$

In this work I have assumed that the sampling interval, T , is 1. Alternatively, one can choose that the *Nyquist* frequency corresponds to 1 so that the sampling frequency is 2. The Octave *signal* toolbox filter design functions use the latter convention.

Filter design using analog prototypes proceeds as follows:

- the critical frequencies in the z -plane are determined
- the critical frequencies are mapped to the s -plane and used to design the s -plane prototype
- the bi-linear transform is used to convert that prototype to the z -plane

K.1.3 Design of second order Butterworth digital filters with the bilinear transform

For the Butterworth first order low-pass section:

$$\begin{aligned} H_{\frac{n+1}{2}}(z) &= \frac{\omega_c (1 + z^{-1})}{(\omega_c + 1) + (\omega_2 - 1) z^{-1}} \\ &= d + \frac{q z^{-1}}{1 + p z^{-1}} \end{aligned}$$

where

$$\begin{aligned} d &= \frac{\omega_c}{\omega_c + 1} \\ q &= \frac{2\omega_c}{(\omega_c + 1)^2} \\ p &= \frac{\omega_c - 1}{\omega_c + 1} \end{aligned}$$

For the Butterworth second order low-pass section:

$$\begin{aligned} H_k(z) &= \frac{g [1 + z^{-1}]^2}{a_0 + a_1 z^{-1} + a_2 z^{-2}} \\ &= d_0 + \frac{q_1 z^{-1} + q_2 z^{-2}}{1 + p_1 z^{-1} + p_2 z^{-2}} \end{aligned}$$

where:

$$\begin{aligned} g &= \omega_c^2 \\ a_0 &= 1 - 2\omega_c \cos \theta_k + \omega_c^2 \\ a_1 &= 2(\omega_c^2 - 1) \\ a_2 &= 1 + 2\omega_c \cos \theta_k + \omega_c^2 \\ d_0 &= \frac{g}{a_0} \\ p_1 &= \frac{a_1}{a_0} \\ p_2 &= \frac{a_2}{a_0} \\ q_1 &= d_0(2 - p_1) \\ q_2 &= d_0(1 - p_2) \end{aligned}$$

Similarly, for the first order high-pass section:

$$\begin{aligned} H_{\frac{n+1}{2}}(z) &= \frac{(1 - z^{-1})}{(\omega_c + 1) + (\omega_c - 1)z^{-1}} \\ &= \frac{d}{w_c} - \frac{qz^{-1}}{1 + pz^{-1}} \end{aligned}$$

and for the Butterworth second order high-pass section:

$$\begin{aligned} H_k(z) &= \frac{[1 - z^{-1}]^2}{a_0 + a_1 z^{-1} + a_2 z^{-2}} \\ &= t_0 + \frac{t_1 z^{-1} + t_2 z^{-2}}{1 + p_1 z^{-1} + p_2 z^{-2}} \end{aligned}$$

where

$$\begin{aligned} t_0 &= \frac{d_0}{g} \\ t_1 &= -\frac{d_0}{g}(2 + p_1) \\ t_2 &= \frac{q_2}{g} \end{aligned}$$

K.2 Low passband sensitivity IIR filters

Vaidyanathan *et al.* [116, 113] describe the synthesis of IIR digital filters as the parallel connection of two all-pass filters. The resulting filter has low coefficient sensitivity if the all-pass filter implementation is *structurally loss-less* (ie: the all-pass transfer function is preserved when the coefficients are truncated).

K.2.1 Structural Boundedness

Consider the N -th order IIR filter

$$G(z) = \frac{P(z)}{D(z)} = \frac{p_0 + p_1 z^{-1} + \cdots + p_N z^{-N}}{1 + d_1 z^{-1} + \cdots + d_N z^{-N}}$$

where the coefficients p_i and d_i are real. We wish to design a structure with multiplier coefficients m_0, m_1, \dots such that the sensitivity of $|G(e^{i\omega})|$ with respect to each m_i is very small in the pass-band. If $|G(e^{i\omega})| \leq 1$ for all ω regardless of the values of the multipliers (so long as they are within a certain range) then the implementation is called *structurally bounded* or *structurally passive* and $G(z)$ is called *bounded real*. If $|G(e^{i\omega})| = 1$ for certain frequencies ω_k in the passband, then at those frequencies, when an m_i is perturbed the value of $|G(e^{i\omega})|$ can only decrease. In other words the first-order sensitivity is zero at ω_k

$$\left. \frac{\partial |G(e^{i\omega_k})|}{\partial m_i} \right|_{m_i=m_{i_0}} = 0 \quad \forall i, \forall k$$

Now consider a stable all-pass function, $A_1(z)$

$$A_1(z) = \frac{a_m + a_{m-1}z^{-1} + \cdots + z^{-m}}{1 + a_1 z^{-1} + \cdots + a_m z^{-m}}$$

$$|A_1(e^{i\omega})| = 1$$

where a_k are real. A number of well-known structures exist for which the mirror images of the denominator and numerator coefficients are preserved in spite of multiplier quantization. Such implementations are called *structurally lossless*.

Now consider a parallel connection of two stable all-pass filters $A_1(z)$ and $A_2(z)$ with

$$A_2(z) = \frac{b_n + b_{n-1}z^{-1} + \cdots + z^{-n}}{1 + b_1 z^{-1} + \cdots + b_n z^{-n}}$$

and

$$G(z) = \frac{1}{2} [A_1(z) + A_2(z)]$$

Since $A_1(z)$ and $A_2(z)$ are all-pass functions:

$$A_1(z) = z^{-n_1} \frac{\hat{D}_1(z)}{D_1(z)}$$

$$A_2(z) = z^{-n_2} \frac{\hat{D}_2(z)}{D_2(z)}$$

where n_1 and n_2 are non-negative, $\hat{D}_1(z)$ denotes the mirror image of $D_1(z)$ and

$$G(z) = \frac{1}{2} \left[\frac{z^{-n_1} D_2(z) \hat{D}_1(z) + z^{-n_2} D_1(z) \hat{D}_2(z)}{D_1(z) D_2(z)} \right]$$

If $A_1(z)$ and $A_2(z)$ are minimal and if $D_1(z)$ and $D_2(z)$ have no common factors then there is no pole-zero cancellation and $G(z)$ has order $N = n + m$.

On the unit circle

$$G(e^{i\omega}) = \frac{1}{2} [e^{i\theta_1(\omega)} + e^{i\theta_2(\omega)}]$$

where $\theta_1(\omega)$ and $\theta_2(\omega)$ are real-valued functions of ω . Thus,

$$|G(e^{i\omega})| = \frac{1}{2} \left| 1 + e^{i[\theta_2(\omega) - \theta_1(\omega)]} \right|$$

and if $A_1(z) \neq A_2(z)$ then $G(z)$ cannot be all-pass. Also, if $A_1(z)$ and $A_2(z)$ are implemented so that they remain all-pass in spite of parameter quantisation, then $|G(e^{i\omega})| \leq 1$ for all ω . Accordingly, the structural lossless-ness of $A_1(z)$ and $A_2(z)$ induces structural boundedness in $G(z)$.

K.2.2 Filter realisation as the sum of all-pass functions

Consider a typical N -th order bounded real transfer function $G(z) = P(z)/D(z)$ where $P(z)$ is symmetric, i.e.: $p_k = p_{N-k}$. Now consider another transfer function $H(z)$ where

$$\begin{aligned} H(z) &= \frac{Q(z)}{D(z)} \\ &= \frac{q_0 + q_1 z^{-1} + \cdots + q_N z^{-N}}{1 + d_1 z + \cdots + d_N z^{-N}} \end{aligned}$$

and $H(z)$ is complementary to $G(z)$

$$|H(e^{j\omega})|^2 = 1 - |G(e^{j\omega})|^2$$

In terms of the z -variable

$$\tilde{P}(z)P(z) + \tilde{Q}(z)Q(z) = \tilde{D}(z)D(z)$$

where $\tilde{P}(z) = P(z^{-1})$ etc.

Computation of the spectral factor $Q(z)$ is simplified by the anti-symmetric nature of its coefficients.

$$Q^2(z) = P^2(z) - z^{-N}D(z^{-1})D(z)$$

$D(z)$ and $P(z)$ are known so the right hand side can be written

$$R(z) = \sum_{n=0}^{2N} r_n z^{-n}$$

Then the coefficients of $Q(z)$ are related to r_n by

$$r_n = \sum_{k=0}^n q_k q_{n-k}$$

and the q_k can be computed recursively

$$\begin{aligned} q_0 &= \sqrt{r_0} \\ q_1 &= \frac{r_1}{2q_0} \\ q_n &= \frac{r_n - \sum_{k=1}^{n-1} q_k q_{n-k}}{2q_0}, \quad 2 \leq n \leq N \end{aligned}$$

The spectral factor, $Q(z)$ is calculated by Octave function *spectralfactor*.

Assume $G(z)$ is such that $Q(z)$ is anti-symmetric i.e.: $q_i = -q_{N-i}$. So

$$\begin{aligned} \tilde{P}(z) &\triangleq P(z^{-1}) = z^N P(z) \\ \tilde{Q}(z) &\triangleq Q(z^{-1}) = -z^N Q(z) \end{aligned}$$

and

$$\begin{aligned} [P(z) + Q(z)][P(z) - Q(z)] &= z^{-N}D(z)D(z^{-1}) \\ [P(z) + Q(z)][P(z^{-1}) + Q(z^{-1})] &= D(z)D(z^{-1}) \end{aligned}$$

Moreover

$$P(z^{-1}) + Q(z^{-1}) = z^N [P(z) - Q(z)]$$

Hence the zeros of $P(z) + Q(z)$ are the reciprocals of the zeros of $P(z) - Q(z)$. Since $G(z)$ is stable, none of its poles are on the unit circle and

$$P(z) + Q(z) \neq 0, \quad |z| = 1$$

Let z_1, z_2, \dots, z_r be the zeros of $P(z) + Q(z)$ inside the unit circle and let $z_{r+1}, z_{r+2}, \dots, z_N$ be those outside. Then

$$D(z) = \prod_{k=1}^r (1 - z^{-1}z_k) \prod_{k=r+1}^N (1 - z^{-1}z_k^{-1})$$

and

$$[P(z) + Q(z)][P(z) - Q(z)] = \left[\prod_{k=1}^r (1 - z^{-1}z_k) \prod_{k=r+1}^N (1 - z^{-1}z_k^{-1}) \right] \left[\prod_{k=1}^r (z^{-1} - z_k) \prod_{k=r+1}^N (z^{-1} - z_k^{-1}) \right]$$

From which

$$\begin{aligned} P(z) + Q(z) &= \alpha \left[\prod_{k=1}^r (1 - z^{-1}z_k) \prod_{k=r+1}^N (z^{-1} - z_k^{-1}) \right] \\ P(z) - Q(z) &= \frac{1}{\alpha} \left[\prod_{k=1}^r (z^{-1} - z_k) \prod_{k=r+1}^N (1 - z^{-1}z_k^{-1}) \right] \end{aligned}$$

where α is a real constant. This leads to the equations

$$\begin{aligned} G(z) + H(z) &= \frac{P(z) + Q(z)}{D(z)} = \alpha \prod_{k=r+1}^N \left(\frac{z^{-1} - z_k^{-1}}{1 - z^{-1}z_k^{-1}} \right) \\ G(z) - H(z) &= \frac{P(z) - Q(z)}{D(z)} = \frac{1}{\alpha} \prod_{k=1}^r \left(\frac{z^{-1} - z_k}{1 - z^{-1}z_k} \right) \end{aligned}$$

Thus

$$\begin{aligned} G(z) + H(z) &= \alpha A_1(z) \\ G(z) - H(z) &= \frac{1}{\alpha} A_2(z) \end{aligned}$$

where $A_1(z)$ and $A_2(z)$ are stable all-pass functions of order $N - r$ and r respectively

$$\begin{aligned} A_1(z) &= \prod_{k=r+1}^N \left(\frac{z^{-1} - z_k^{-1}}{1 - z^{-1}z_k^{-1}} \right) \\ A_2(z) &= \prod_{k=1}^r \left(\frac{z^{-1} - z_k}{1 - z^{-1}z_k} \right) \end{aligned}$$

The complementarity condition requires $\alpha^2 = 1$ so, finally

$$\begin{aligned} G(z) &= \frac{1}{2} [A_1(z) + A_2(z)] \\ H(z) &= \frac{1}{2} [A_1(z) - A_2(z)] \end{aligned}$$

and $G(z)$ is implemented as the parallel combination of two all-pass functions.

This low-sensitivity realisation is summarised in Algorithm K.1.

The classical Butterworth, Chebyshev and Cauer low-pass digital filters of odd order satisfy the following conditions and can be implemented as the combination of two stable all-pass functions

1. N is odd
2. $\frac{\partial^k |G(e^{j\omega})|}{\partial \omega^k} \Big|_{\omega=0} = 0$ for $k = 1, 2, \dots, n_0$ where n_0 is some odd integer
(In other words, $|G(e^{j\omega})|$ has odd-order tangency at zero frequency).
3. $|G(1)| = 1$
4. There are $(N - n_0)/2$ frequencies in the range $0 < \omega < \pi$ where $|G(e^{j\omega})| = 1$

Other filter pass-bands are obtained by frequency transformation.

The Octave script `vaidyanathan_allpass_example.m` implements the example transfer function shown in [116, Section V].

Algorithm K.1 Filter realisation as the sum of all-pass functions

Let $G(z) = P(z)/D(z)$ be a bounded real function of order N and let $P(z)$ be symmetric i.e.: $p_i = p_{N-i}$. In addition, let $G(z)$ be such that an anti-symmetric polynomial $Q(z)$ (i.e.: $q_i = -q_{N-i}$) exists such that

$$\tilde{P}(z)P(z) + \tilde{Q}(z)Q(z) = \tilde{D}(z)D(z)$$

$G(z)$ can be implemented as the combination of two stable all-pass functions $A_1(z)$ and $A_2(z)$

$$G(z) = \frac{1}{2} [A_1(z) + A_2(z)]$$
$$H(z) = \frac{1}{2} [A_1(z) - A_2(z)]$$

Furthermore, $H(z)$ is also bounded real and is doubly complementary to $G(z)$.

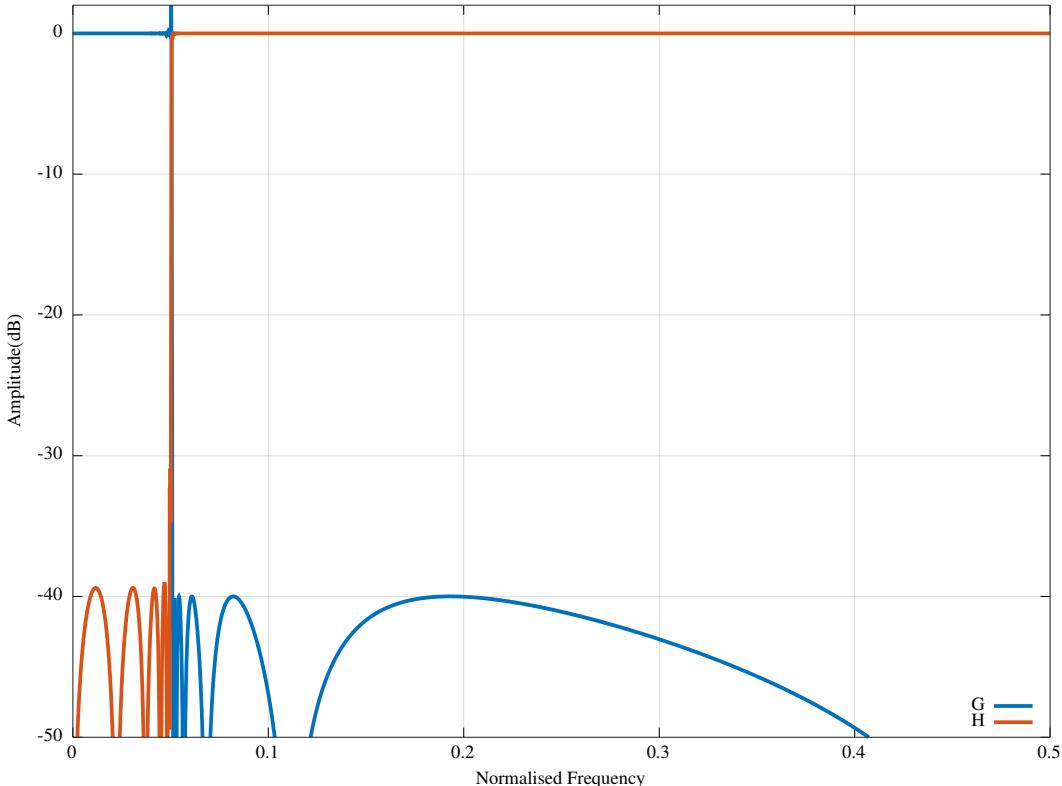

Figure K.1: 13th order elliptic filter, complementary filter and summed transfer functions

K.2.3 A note on the numerical calculation of the spectral factor

The Octave implementation of the calculation of the spectral factor is in the Octave function file *spectralfactor.m*. The file *spectralfactor.cc* shows a C++ version of *spectralfactor* using the *MPFR* arbitrary precision floating point library [75, 126, 1]. The mantissa precision is set to 256 bits. The Octave script *spectralfactor_test.m* illustrates calculation of the spectral factor for a 13th order elliptic filter with cut-off frequency $0.05f_S$, pass-band ripple 0.0005dB and stop-band ripple 40dB using *spectralfactor.oct*. Figures K.1 and K.2 show the transfer functions of the elliptic filter, the spectral factor complementary filter and the summed transfer function. The summed response ripple is satisfactory for order 13 but fails catastrophically for order 15. I suspect that this is due to roundoff error in the original calculation of the elliptic filter coefficients that is visible in the transition band detailed view. The prototype elliptic filter response appears to be not structurally bounded.

K.2.4 Examples of parallel all-pass filter synthesis

3rd order Butterworth low-pass filter

The Octave script *but3NSPA_test.m* shows synthesis as a parallel combination of two all-pass filters of the 3rd order Butterworth filter used in the example of Part I. Annotated results of the script follow.

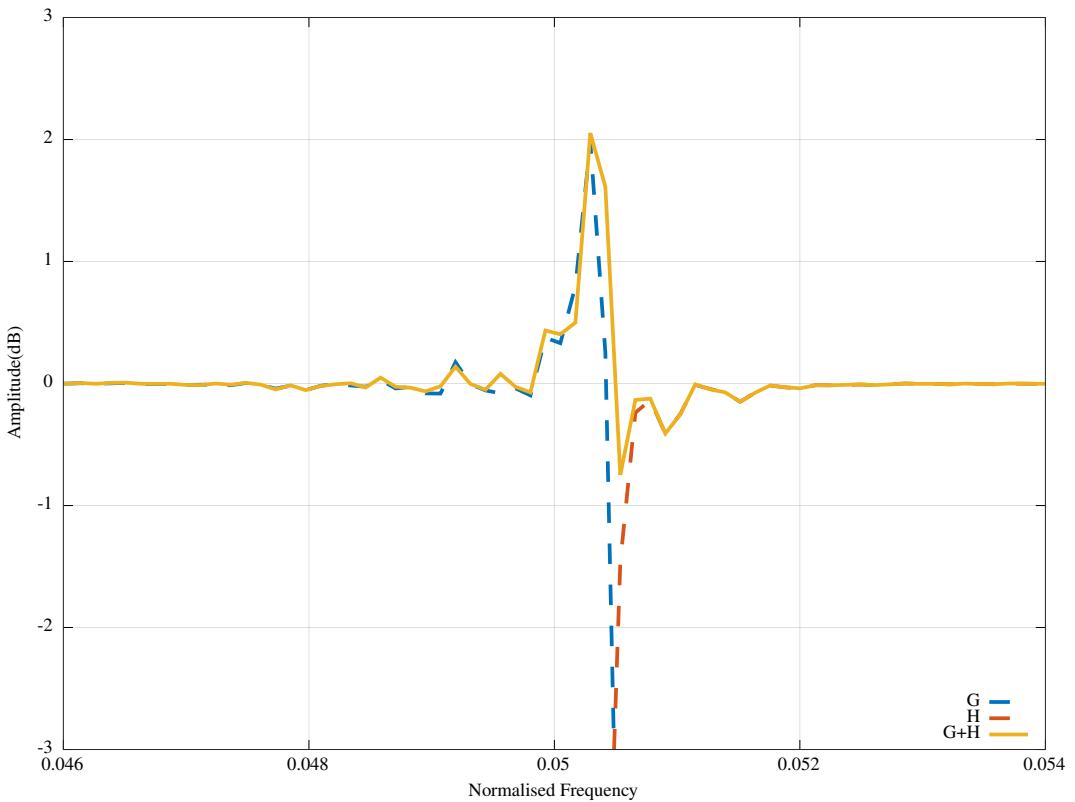

Figure K.2: 13th order elliptic filter, complementary filter and summed transfer functions transition band detail

The numerator and denominator polynomials, $N(z)$ and $D(z)$ are:

$$\begin{aligned} n &= 0.0028982 \quad 0.0086946 \quad 0.0086946 \quad 0.0028982 \\ d &= 1.00000 \quad -2.37409 \quad 1.92936 \quad -0.53208 \end{aligned}$$

The spectral factor $Q(z)$ is:

$$q = 0.72944 \quad -2.18832 \quad 2.18832 \quad -0.72944$$

The sum $N(z) + Q(z)$ has roots:

$$\begin{aligned} z &= 1.12486 + 0.31652i \\ &\quad 1.12486 - 0.31652i \\ &\quad 0.72654 + 0.00000i \end{aligned}$$

The polynomials for the all-pass components are:

$$\begin{aligned} A1 &= 0.73234 \quad -1.64755 \quad 1.00000 \\ A2 &= -0.72654 \quad 1.00000 \end{aligned}$$

After quantising to three 10-bit signed-digits the coefficients for the normalised-scaled lattice implementation are:

```
A1s10f = [      -488,      376 ]/512;
A1s11f = [       158,      352 ]/512;
A1s20f = [      -488,      376 ]/512;
A1s00f = [       158,      352 ]/512;
A1s02f = [      488,     -376 ]/512;
A1s22f = [      158,      352 ]/512;
```

and

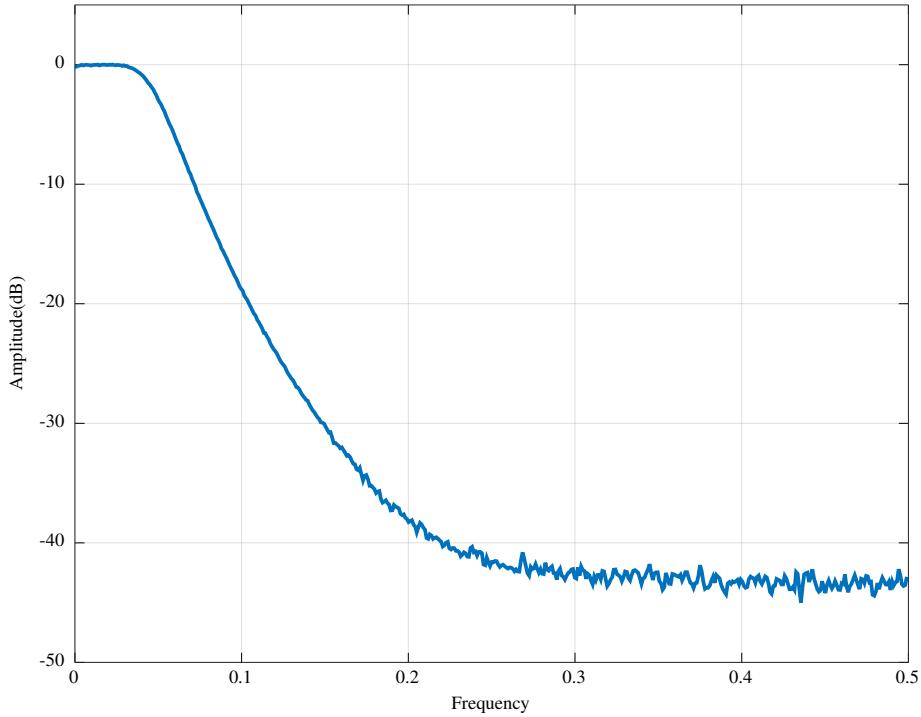

Figure K.3: Simulated amplitude response of the 3rd order Butterworth filter synthesised as the parallel combination of two all-pass filters implemented as normalised-scaled lattices with 10-bit 3-signed-digit coefficients

```

A2s10f = [      -368 ]/512;
A2s11f = [      352 ]/512;
A2s20f = [     -368 ]/512;
A2s00f = [      352 ]/512;
A2s02f = [      368 ]/512;
A2s22f = [      352 ]/512;

```

The noise gains of each part with three signed-digit coefficients are:

```

A1ngapABCDf =  3.1899
A2ngapABCDf =  0.95500

```

The estimated and measured round-off noise variances at the combined all-pass output are:

```

est_varA1yapd =  0.34916
varA1yapd =  0.34396
est_varA2yapd =  0.16292
varA2yapd =  0.16222
est_varyapd =  0.25302
varyapd =  0.26062

```

The standard deviations of the internal state delay storage elements are:

```

A1stdxf =  133.64   130.73
A2stdxf =  128.18

```

The amplitude response found from the cross-correlation of the input and output is shown in Figure K.3.

6th order Butterworth band-pass

The Octave script *butt6NSPABP_test.m* shows synthesis as a parallel combination of two all-pass filters of a 6th order band-pass Butterworth filter. Annotated results of the script follow.

The prototype filter has cutoff frequency:

```
fc = 0.25000
```

The numerator and denominator polynomials, $N(z)$ and $D(z)$ are:

```
n = 0.16667 0.50000 0.50000 0.16667  
d = 1.0000e+00 -3.0531e-16 3.3333e-01 -1.8504e-17
```

The spectral factor $Q(z)$ is:

```
q = 0.16667 -0.50000 0.50000 -0.16667
```

The sum $N(z) + Q(z)$ has roots

```
z = 0.00000 + 1.73205i  
0.00000 - 1.73205i  
0.00000 + 0.00000i
```

The polynomials for the all-pass components of the prototype filter are:

```
Aap1 = 3.3333e-01 0.0000e+00 1.0000e+00  
Aap2 = 0.0000e-00 1.0000e+00
```

The frequency transformation polynomial for a band-pass filter with band edges $0.2f_S$ and $0.25f_S$ is

```
p = 1.00000 -0.27346 0.72654
```

The all-pass polynomials of the parallel components of the band-pass filter are

```
A1BP = 1.0000e+00 -6.7309e-01 2.3655e+00 -7.8886e-01 1.3655e+00
```

and

```

A2stdxf =  1.2674e+02  1.2657e+02

```

The amplitude response found from the cross-correlation of the input and output is shown in Figure K.4.

K.3 Design of Elliptic IIR filters with a reduced number of multipliers

Lutovac and Milić [79, 90] describe the design of minimum Q-factor elliptic filters having a reduced number of multipliers. These filters are based on the continuous time minimal-Q elliptic filter design of *Rabrenović and Lutovac* [28, 27]. The minimal-Q factor elliptic filters have reduced component sensitivity at the expense of increased filter order or reduced selectivity.

K.3.1 Elliptic filter design with the *Landen transformation*

In this section I follow the tutorial paper by *Orchard and Willson* [48]. Elliptic filters are an application of the *Jacobian elliptic functions* and *elliptic integrals*. The original purpose of the elliptic functions was to invert the integral that finds the arc length of an ellipse. For example, the elliptic function $w = \operatorname{sn} u$ is defined by the *incomplete elliptic integral*:

$$u = \int_0^w \frac{dt}{\sqrt{(1-t^2)(1-\kappa^2t^2)}} \quad (\text{K.1})$$

For elliptic filter design, the *modulus*, κ , is real and $0 \leq \kappa \leq 1$. The *modular angle*, θ , is defined by $\kappa = \sin \theta$ and the *complementary modulus* is $\kappa' = \cos \theta$. The elliptic functions are *doubly-periodic* functions on the complex plane with *quarter-periods* K and K' , where:

$$K = \int_0^1 \frac{dt}{\sqrt{(1-t^2)(1-\kappa^2t^2)}}$$

and similarly for K' . The elliptic functions are a generalisation of the circular and hyperbolic trigonometric functions. For $\kappa = 0$ and $K = \frac{\pi}{2}$, Equation K.1 is the arcsin function. For $\kappa = 1$ and $K = \infty$, Equation K.1 is the arctanh function.

The magnitude-squared response of an n -th order continuous time elliptic low-pass filter is:

$$|H(\omega)|^2 = \frac{1}{1 + \epsilon^2 R_n^2(\omega, \omega_a)}$$

where $R_n(\omega, \omega_a)$ is an n -th order elliptic rational function, ϵ is the pass-band ripple factor and $\omega_a = \frac{1}{\kappa}$ is the stop-band edge frequency. Both ω_a and the frequency ω are normalised to ω_p , the pass-band edge frequency. In the pass-band R_n varies between 0 and 1 so that in the pass-band $|H(\omega)|^2$ varies between $\frac{1}{1+\epsilon^2}$ and 1. In the stop-band $|H(\omega)|^2$ varies between 0 and $\frac{1}{1+\epsilon^2 L_n^2}$ where $L_n = R_n(\omega_a)$ is called the discrimination factor.

Orchard and Willson show how to derive a continuous time elliptic filter with filter order n , pass-band ripple α_p and stop-band ripple α_a from the s-plane poles and zeros of an initial *Chebyshev Type 1* filter. They comment that:

The fact that the degree n must be an integer means that the smallest value of n that meets the specification will normally provide some margin in performance that should be distributed amongst the quantities α_p , α_a and κ . How best to do this requires some engineering judgement ...

The *Landen transformation* relates the elliptic functions, $\operatorname{ns}(uG, \gamma)$ and $\operatorname{ns}(uK, \kappa)$, for which the quarter-periods have $\frac{2G'}{G} = \frac{K'}{K}$ [48, Equation 8]:

$$\operatorname{ns}(uG, \gamma) = \frac{1}{1 + \kappa} \left[\operatorname{ns}(uK, \kappa) + \frac{\kappa}{\operatorname{ns}(uK, \kappa)} \right]$$

Orchard and Willson [48, Section IV] derive a recurrence relation for the modulus, κ , that appears in successive Landen transformations:

$$\kappa_{n+1} = \left[\frac{\kappa_n}{1 + \sqrt{1 - \kappa_n^2}} \right]^2$$

This sequence, κ_n , tends rapidly to zero and the value of the elliptic function is considered to be equal to that of the corresponding circular function value. In this case, $\operatorname{ns}(z, \kappa) \rightarrow \operatorname{cosec} z$ as $\kappa \rightarrow 0$. The required elliptic function value at the original modulus, κ_0 , is found by reversing the recurrence:

$$\kappa_n = \frac{2\sqrt{\kappa_{n+1}}}{1 + \kappa_{n+1}}$$

so that:

$$\text{ns}(aK_n, \kappa_n) = \frac{1}{1 + \kappa_{n+1}} \left[\text{ns}(aK_{n+1}, \kappa_{n+1}) + \frac{\kappa_{n+1}}{\text{ns}(aK_{n+1}, \kappa_{n+1})} \right]$$

The normalized n -th order Chebyshev Type 1 filter with pass-band peak-to-peak ripple $\alpha_p = 10 \log_{10} (1 + \varepsilon^2)$ dB is defined by the parametric equations for the squared-magnitude of the filter attenuation^b:

$$A(s) A(-s) = 1 + \varepsilon^2 \cos^2 \frac{nu\pi}{2}$$

$$\Omega = \cos \frac{u\pi}{2}$$

Orchard and *Willson* generalise the Chebyshev filter by changing the cosine function into the appropriate elliptic function equivalent. The resulting parametric equations are:

$$A(s) A(-s) = 1 + \varepsilon^2 \text{cd}^2(nuG, \gamma)$$

$$\Omega = \text{cd}(uK, \kappa)$$

$$\frac{nK'}{K} = \frac{G'}{G}$$

The stop-band loss is $\alpha_a = 10 \log_{10} \left(1 + \frac{\varepsilon^2}{\gamma^2} \right)$ dB. The following path in the complex u -plane maps the u parameter from the complex plane to the Ω frequency axis with the desired amplitude response:

- Pass band: $u = 1$ to $u = 0$ maps to $\Omega = 0$ to $\Omega = 1$, $\text{cd}(nuG, \gamma)$ varies between 1 and -1
- Transition band: $u = 0$ to $u = i\frac{K'}{K}$ maps to $\Omega = 1$ to $\Omega = \frac{1}{\kappa}$
- Stop band: $u = i\frac{K'}{K}$ to $u = 1 + i\frac{K'}{K}$ maps to $\Omega = \frac{1}{\kappa}$ to $\Omega = \infty$, $\text{cd}(nuG, \gamma)$ has minimums at $\frac{1}{\gamma}$ and maximums at $-\frac{1}{\gamma}$

The cd elliptic function is used because it has a zero at the start of the path, at $u = 1$, and a pole at the end, at $u = 1 + i\frac{K'}{K}$.

Orchard and *Willson* show a *Matlab* file, *ellipap1.m* [48, Figure 7], that, given the filter order and pass-band and stop-band ripples, calculates the gain, poles and zeros of a continuous time elliptic filter by the *Landen transformation* of the poles and zeros of a *Type 1 Chebyshev* filter with the same pass-band and stop-band attenuation specifications.

K.3.2 Design of elliptic filters with minimal-Q

Rabrenović and *Lutovac* [28, 27] derive the properties of a continuous time elliptic filter with poles having minimal-Q. The poles of the filter lie on a circle with radius $\sqrt{\omega_a}$ and the ripples in the pass-band and stop-band squared-magnitude response are equal:

$$1 - \frac{1}{1 + \epsilon_{minQ}^2} = \frac{1}{1 + \epsilon_{minQ}^2 L_n^2}$$

so that for the minimal-Q elliptic filter:

$$\epsilon_{minQ} = \frac{1}{\sqrt{L_n}}$$

Lutovac and *Milić* [90] describe the design of an odd order, n , discrete-time elliptic filter implemented as the sum of an odd and an even order all-pass filter in which the all-pass filter components are expressed as products of second-order all-pass lattice sections:

$$\frac{b_m + a_m (1 + b_m) z^{-1} + z^{-2}}{1 + a_m (1 + b_m) z^{-1} + b_m z^{-2}}$$

with $m > 1$, and, for the odd-order filter, a first-order section:

$$\frac{a_1 + z^{-1}}{1 + a_1 z^{-1}}$$

^b*Orchard* prefers the convention that $A(s)$ represents the filter attenuation, i.e.: the ratio of *input* to *output*.

For the second-order sections, with the poles at $z_m = r_m e^{\pm i\theta_m}$:

$$a_m = -2 \frac{r_m \cos \theta_m}{1 + r_m^2}$$

$$b_m = r_m^2$$

where $m = 2, \dots, \frac{n+1}{2}$. For the first-order section:

$$a_1 = -r_1$$

Following the notation of *Lutovac* and *Milić* [90] suppose that the digital filter specification has pass-band and stop-band frequencies F_p and F_a and corresponding pass-band ripple, A_p , and stop-band attenuation, A_a , given in dB. Assume that the digital filter is found by transformation of a prototype continuous time minimal-Q elliptic filter with a normalised pass band edge frequency of $\omega = 1$.

The pass-band and stop-band attenuations of the filter are $\alpha_p \leq A_p$ and $\alpha_a \geq A_a$ with:

$$\alpha_p = 10 \log_{10} \left(1 + \frac{1}{L_n} \right)$$

and:

$$\alpha_a = 10 \log_{10} (1 + L_n)$$

The 3dB frequency is given by:

$$\tan^2 \pi f_{3dB} = \tan \pi f_p \tan \pi f_a$$

The s -plane poles of the continuous time prototype are distributed around the circle $|s| = \sqrt{\omega_a}$. The bilinear transform

$$s = \frac{2}{T} \frac{z-1}{z+1}$$

where

$$T = 2 \frac{\sqrt{\omega_a}}{\tan \pi f_{3dB}} = 2 \tan \pi f_p$$

maps that circle onto a circle in the z -plane orthogonal to the unit circle and centred on the real axis of the z -plane at $z = x_0$ with the s -plane point $i\sqrt{\omega_a}$ mapped to the z -plane point $z_{3dB} = e^{i2\pi f_{3dB}}$ so that:

$$x_0 = \frac{1}{\cos 2\pi f_{3dB}} = \frac{1 - \tan^2 \pi f_{3dB}}{1 + \tan^2 \pi f_{3dB}}$$

For $m = 1$, the first order section has:

$$a_1 = -x_0 \left(1 - \sqrt{1 - \frac{1}{x_0^2}} \right)$$

For $m > 1$, the second-order all-pass filter sections have, as shown in [90, Figure 4]:

$$r_m^2 + x_0^2 - 2r_m x_0 \cos \theta_m = x_0^2 - 1$$

so that:

$$2r_m \cos \theta_m = \frac{1 + r_m^2}{x_0}$$

and:

$$a_m = a = -\frac{1}{x_0}$$

The range of permitted values of a is:

$$-\frac{1 - \tan^2 \pi F_p}{1 + \tan^2 \pi F_p} < a < -\frac{1 - \tan^2 \pi F_a}{1 + \tan^2 \pi F_a}$$

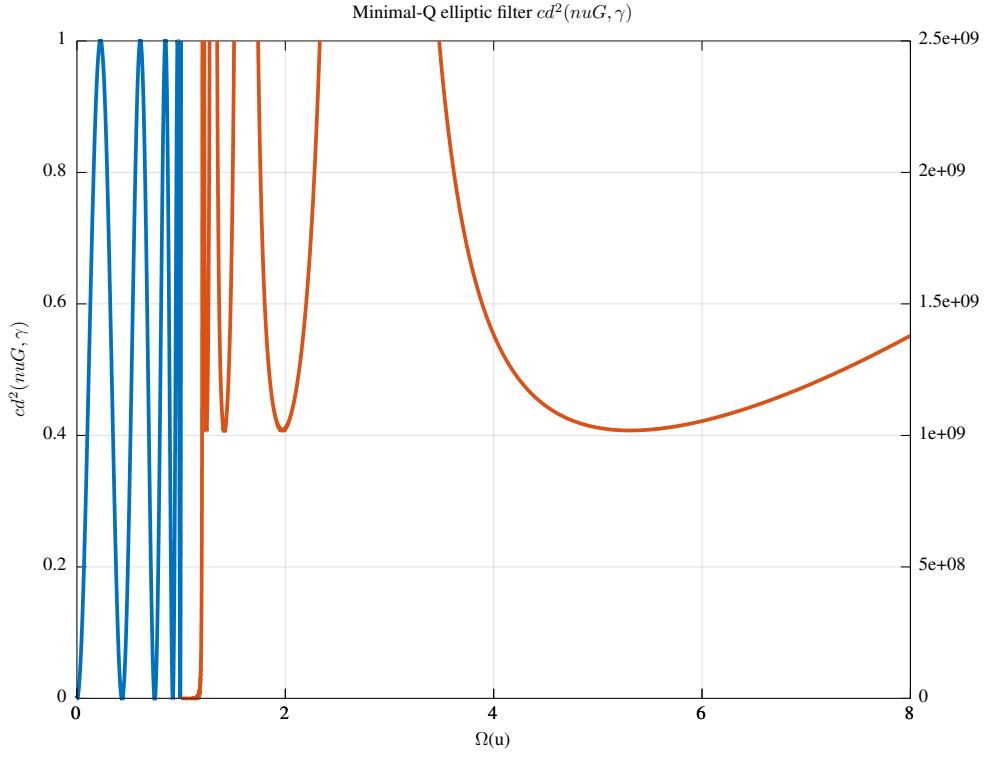

Figure K.5: Values of Ω and $cd^2(nuG, \gamma)$ plotted as the complex parameter u varies

The minimal-Q elliptic filter is implemented with a reduced number of multipliers by choosing a to be a signed-digit number. Lutovac and Milić [90, Appendix A] show that the poles can be selected to alternate between the two all-pass branches with increasing angle or radius.

The Octave file *ellipMinQ_test.m* designs a discrete-time minimal-Q elliptic filter implemented as the sum of parallel all-pass filters. The filter order is $n = 9$, pass-band edge is $F_p = 0.1$, pass-band ripple specification is $0.1dB$, stop-band edge is $F_a = 0.125$, and the stop-band ripple specification is $40dB$. The second order lattice constant, a , set was to $-\frac{3}{4}$ with corresponding $f_{3dB} = 0.115027$. Setting $f_a = Fa$ gives a corresponding $f_p = 0.105715$. The continuous-time s -plane stop-band edge angular frequency is $\omega_a = 1.201010$ with elliptic filter moduluses $\kappa = 0.832632$ and $\gamma = 3.1329e - 05$. The calculation of the continuous-time s -plane pole and zero locations follows Orchard and Willson [48, Fig.6]. The resulting pass-band ripple is $\alpha_p = 0.0001361dB$ and the stop-band ripple is $\alpha_a = 45.04dB$. Figure K.5 shows the values of Ω and $cd^2(nuG, \gamma)$ plotted as the complex parameter u varies. Figure K.6 shows the amplitude response of the continuous-time s -plane filter when calculated with the transfer function derived from the s -plane gain, poles and zeros. Figure K.7 shows the pole-zero plot of the corresponding discrete-time z -plane filter. Figure K.8 shows the amplitude response of the discrete-time z -plane filter. The lattice coefficients are:

$$\{a_1, a, b_2, b_3, b_4, b_5\} = [-0.451416, -0.75, 0.350740, 0.619208, 0.822345, 0.949033]$$

The following 8-bit, 3-signed-digit lattice coefficients were found by brute-force search: $[-58, -96, 46, 79, 104, 121]$. The maximum stop-band response of the signed-digit coefficient filter is $-39.12dB$ at 0.1304 . Figure K.9 shows the amplitude response of the corresponding filter.

Figure K.7: Pole-zero plot of the discrete-time z -plane filter

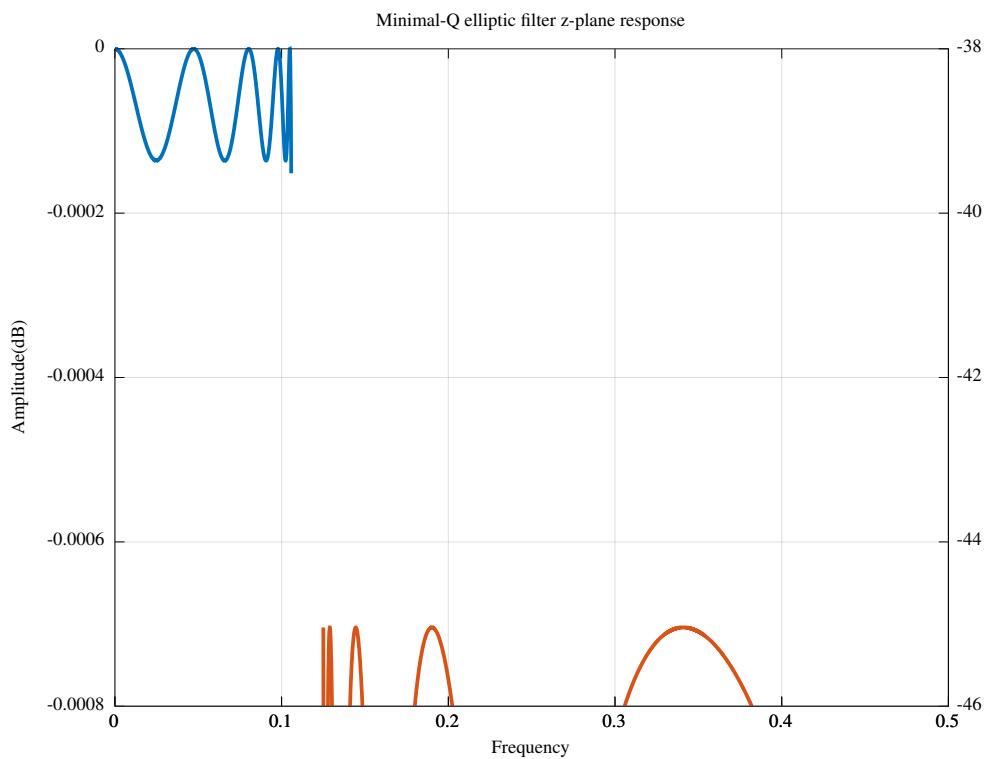

Figure K.8: Amplitude response of the discrete-time z -plane filter

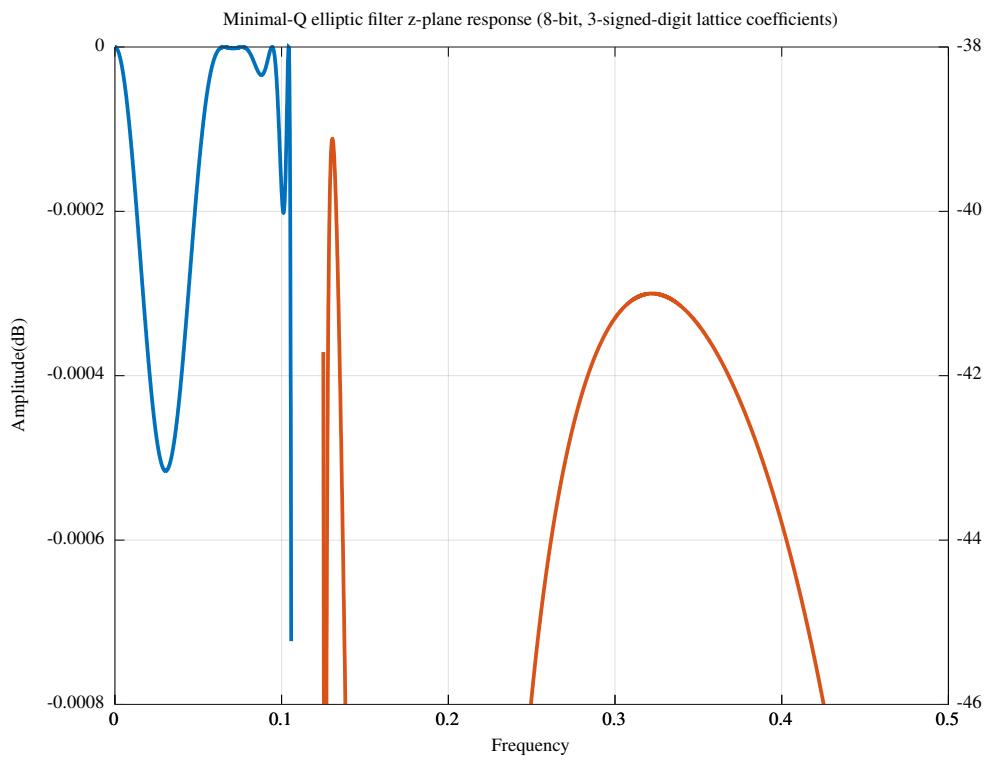

Figure K.9: Amplitude response of the discrete-time z -plane filter with 8-bit, 3-signed-digit coefficients

K.4 Saramäki's method for the design of IIR filters with zeros on the unit circle

Firstly, define the transfer function of an IIR filter:

$$H(z) = K z^{n-m} \frac{\prod_{k=1}^m (z - a_k)}{\prod_{k=1}^n (z - b_k)}$$

The zeros, a_k , and poles, b_k , are real or conjugate pairs. When $n > m$ ($m > n$), $H(z)$ has $n-m$ zeros ($m-n$ poles) at the origin. A stable filter has $|b_k| < 1$. Saramäki [153] describes a procedure for designing an IIR filter with either equi-ripple pass-band and stop-band amplitude response. The algorithm transforms the frequency response so that the pass-band (stop-band) is equi-ripple and the amplitude response in the stop-band (pass-band) is optimised. He claims that the algorithm has improved numerical performance. Also, Saramäki finds that for $n \geq m$, his procedure produces better narrow-band filters than the corresponding elliptic filter. Conversely, when $n < m$, his algorithm produces better wide-band filters.

Write

$$H(z) H\left(\frac{1}{z}\right) = E \frac{\prod_{k=1}^m \left(z + \frac{1}{z}\right) \left(a_k - \frac{1}{a_k}\right)}{\prod_{k=1}^n \left(z + \frac{1}{z}\right) \left(b_k - \frac{1}{b_k}\right)}$$

Saramäki's procedure maps $z + \frac{1}{z}$ to $v + \frac{1}{v}$ so that for $n \geq m$ ($n < m$) the pass-band (stop-band) on the unit circle in the z -plane is mapped to the entire upper unit circle on the v -plane. An equi-ripple pass-band (stop-band) response is obtained by construction. The remaining problem is, for $n \geq m$ ($n < m$), to find adjustable zeros (poles) so that the resulting $H(z)$ has $n-m$ zeros ($m-n$ poles) at the origin and the squared-magnitude function is equiripple in the stop-band (pass-band).

The all-pass function

$$F(v) = \prod_{k=1}^r \left(\frac{1 - v_k v}{v - v_k} \right)$$

is, on the unit circle, $v = e^{i\Omega}$:

$$F(e^{i\Omega}) = e^{if(\Omega)}$$

where:

$$f(\Omega) = \sum_{k=1}^r \left\{ \Omega - 2 \arctan \left[\frac{\sin \Omega - \Im v_k}{\cos \Omega - \Re v_k} \right] \right\}$$

Now define:

$$G\left(v + \frac{1}{v}\right) = \frac{1}{2} \left[F(v) + \frac{1}{F(v)} \right]$$

so that, on the unit circle, $v = e^{i\Omega}$:

$$G\left(v + \frac{1}{v}\right) = \cos f(\Omega)$$

This function has $r+1$ alternating extrema, ± 1 , on $v = e^{i\Omega}$, $0 \leq \Omega \leq \pi$. Its value is $+1$ at $v = 1$ and $(-1)^r$ at $v = -1$.

Saramäki now introduces a mapping from $z = e^{i\omega}$, $\omega_1 \leq \omega \leq \omega_2$, to $v = e^{i\Omega}$, $0 \leq \Omega \leq \pi$:

$$v + \frac{1}{v} = C \left(z + \frac{1}{z} \right) + D$$

where:

$$\begin{aligned} C &= \frac{2}{\cos \omega_1 - \cos \omega_2} \\ D &= -\frac{2(\cos \omega_1 + \cos \omega_2)}{\cos \omega_1 - \cos \omega_2} \end{aligned}$$

K.4.1 Optimisation of a low-pass filter with denominator order higher

When $n \geq m$ set $\omega_1 = 0$ and $\omega_2 = \omega_p$. The resulting transformation maps the pass-band $z = e^{i\omega}$, $0 \leq \omega \leq \omega_p$, to the upper-unit circle $v = e^{i\Omega}$, $0 \leq \Omega \leq \pi$, and the stop-band, $\omega_s \leq \omega \leq \pi$, to the negative real axis part $[\zeta_1, \zeta_2]$. Solving the resulting quadratic equations for ζ_1 and ζ_2 gives:

$$\begin{aligned}\zeta_1 &= -\frac{1}{2} \left[-2C \cos \omega_s - D - \sqrt{(-2C \cos \omega_s - D)^2 - 4} \right] \\ \zeta_2 &= -\frac{1}{2} \left[2C - D - \sqrt{(2C - D)^2 - 4} \right]\end{aligned}$$

The transformed magnitude-squared function is constructed as^c:

$$\hat{H}(v) \hat{H}\left(\frac{1}{v}\right) = \frac{1}{1 + \frac{\Delta_p}{1-\Delta_p} \left[\frac{1}{2} + (-1)^n \frac{1}{4} \left[F(v) + \frac{1}{F(v)} \right] \right]}$$

where

$$F(v) = \prod_{k=1}^n \left(\frac{1 - \alpha_k v}{v - \alpha_k} \right)$$

and $1 - \Delta_p = (1 - \delta_p)^2$, $\delta_p = 1 - 10^{-\frac{dB_{ap}}{20}}$. By design, $\hat{H}(v) \hat{H}\left(\frac{1}{v}\right)$ has $n+1$ alternating extrema 1 and $1 - \Delta_p$ in $v = e^{i\Omega}$, $0 \leq \Omega \leq \pi$. We want to find α_k such that, in the z -plane, $H(z) H\left(\frac{1}{z}\right)$ has $m+1$ alternating extrema, Δ_s and 0, on $z = e^{i\omega}$, $\omega_s \leq \omega \leq \pi$, and $H(z)$ has $n-m$ zeros at the origin. The z -to- v -plane transformation maps $z = 0$ to $v = 0$ so set $\alpha_k = 0$ for $k = m+1, \dots, n$. In addition, since $H(z) H\left(\frac{1}{z}\right)$ has $\lfloor \frac{m}{2} \rfloor$ minima, 0, on $z = e^{i\omega}$, $\omega_s < \omega < \pi$, $\hat{H}(v) \hat{H}\left(\frac{1}{v}\right)$ has $\lfloor \frac{m}{2} \rfloor$ double zeros in the transformed stop-band $[\zeta_1, \zeta_2]$. For m odd, $H(z)$ has a zero at $z = -1$ which is transformed to $v = \zeta_2$. Thus, the $F(v)$ for the optimal $H(z) H\left(\frac{1}{z}\right)$ is:

$$F(\boldsymbol{\alpha}, v) = v^{-(n-m)} \left(\frac{1 - \zeta_2 v}{v - \zeta_2} \right)^q \prod_{k=1}^{\lfloor \frac{m}{2} \rfloor} \left(\frac{1 - \alpha_k v}{v - \alpha_k} \right)^2$$

where $q = 0$ for m even and $q = 1$ for m odd, $\zeta_1 < \alpha_k < \zeta_2$ and $\boldsymbol{\alpha} = [\alpha_1, \dots, \alpha_{\lfloor \frac{m}{2} \rfloor}]$. The gradient of $F(\boldsymbol{\alpha}, v)$ with respect to α_k is:

$$\frac{\partial F(\boldsymbol{\alpha}, v)}{\partial \alpha_k} = 2 \left[\frac{1 - v^2}{(1 - \alpha_k v)(v - \alpha_k)} \right] F(\boldsymbol{\alpha}, v)$$

By construction, $(-1)^n F(\boldsymbol{\alpha}, v) > 0$. The optimisation problem is to find $\boldsymbol{\alpha}$ and the scalar, Λ , such that at the $\lfloor \frac{m}{2} \rfloor + 1$ minima, v_l :

$$\log [(-1)^n F(\boldsymbol{\alpha}, v_l)] = \Lambda$$

Saramäki suggests a Remez-exchange type procedure for solving these non-linear equations. At each iteration, after linearising:

$$\log [(-1)^n F(\boldsymbol{\alpha}, v_l)] + \frac{\nabla_{\boldsymbol{\alpha}} F(\boldsymbol{\alpha}, v_l)}{F(\boldsymbol{\alpha}, v_l)} \Delta \boldsymbol{\alpha} = \Lambda + \Delta \Lambda$$

The initial $\boldsymbol{\alpha}$ are evenly spaced in (ζ_1, ζ_2) and $\Lambda = 0$. The angles, ω_k , of the $\lfloor \frac{m}{2} \rfloor$ complex conjugate zero pairs, $z = e^{\pm i\omega_k}$, of $H(z)$ are found from

$$\alpha_k + \frac{1}{\alpha_k} = 2C \cos \omega_k + D$$

The poles, b_k , of $H(z)$ are found by transforming the n poles, β_k , of $\hat{H}(v) \hat{H}\left(\frac{1}{v}\right)$ that are the solutions of:

$$1 + \frac{\Delta_p}{1 - \Delta_p} \left[\frac{1}{2} + (-1)^n \frac{1}{4} \left[F(\boldsymbol{\alpha}, v) + \frac{1}{F(\boldsymbol{\alpha}, v)} \right] \right] = 0$$

Re-arranging gives:

$$F(\boldsymbol{\alpha}, v) = -(-1)^n \left[\frac{2 - \Delta_p}{\Delta_p} + \sqrt{\left(\frac{2 - \Delta_p}{\Delta_p} \right)^2 - 1} \right]$$

^cHere I follow *Surma-aho* and *Saramäki* [71, Appendix] rather than *Saramäki* [153, Eqn.16]

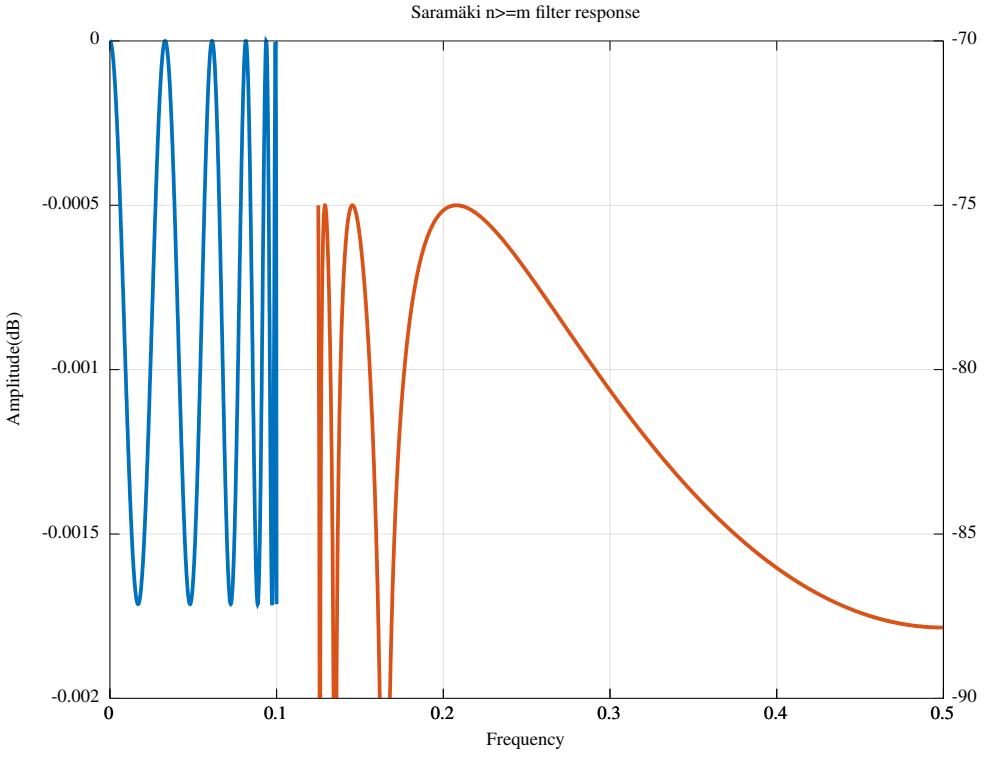

Figure K.10: Amplitude response of an IIR filter with $n = 11$ and $m = 6$, designed with the procedure of Saramäki

If the stop-band ripple, Δ_s , is specified instead of the pass-band ripple, then the corresponding pass-band ripple, Δ_p , is found from the stop-band equi-ripple maximum, $\lambda = (-1)^n F(\alpha, v_l)$:

$$\Delta_p = \frac{1}{1 + \frac{\Delta_s}{1-\Delta_s} \left[\frac{1}{2} + \frac{1}{4} [\lambda + \frac{1}{\lambda}] \right]}$$

The scaling constant, K , is found from the condition $|H(e^{j\omega_p})|^2 = 1 - \Delta_p$.

The Octave function *saramakiFAvLogNewton* implements Saramäki's procedure for $n \geq m$.

The Octave script *saramakiFAvLogNewton_test.m* designs an IIR filter with pass-band edge frequency, $f_p = 0.1$, stop-band edge frequency, $f_s = 0.125$, stop-band ripple, $dBas = 75$, denominator order, $n = 11$, and numerator order, $m = 6$. The resulting pass-band peak-to-peak ripple is 0.001713dB. Figure K.10 shows the amplitude response of the filter. Figure K.11 shows the pole-zero plot of the filter. The numerator and denominator polynomials are, respectively:

```

K.4.2 Optimisation of a low-pass filter with denominator order lower

When $n < m$ set $\omega_1 = \omega_s$ and $\omega_2 = \pi$. The resulting transformation maps the stop-band $z = e^{i\omega}, \omega_s \leq \omega \leq \pi$, to the upper-unit circle $v = e^{i\Omega}, 0 \leq \Omega \leq \pi$, and the pass-band, $0 \leq \omega \leq \omega_p$, to the positive real axis part $[\zeta_1, \zeta_2]$. Solving the resulting quadratic equations for ζ_1 and ζ_2 gives:

$$\begin{aligned}\zeta_1 &= \frac{1}{2} \left[2C + D - \sqrt{(2C + D)^2 - 4} \right] \\ \zeta_2 &= \frac{1}{2} \left[2C \cos \omega_p + D - \sqrt{(2C \cos \omega_p + D)^2 - 4} \right]\end{aligned}$$

The transformed magnitude-squared function, $\hat{H}(v) \hat{H}\left(\frac{1}{v}\right)$, having $m+1$ alternating extrema Δ_s and 0 on $v = e^{i\Omega}, 0 \leq \Omega \leq \pi$ is constructed as:

$$\hat{H}(v) \hat{H}\left(\frac{1}{v}\right) = \Delta_s \left[\frac{1}{2} + \frac{1}{4} \left(F(v) + \frac{1}{F(v)} \right) \right]$$

where:

$$F(v) = \prod_{k=1}^m \frac{1 - \beta_k v}{v - \beta_k}$$

is an all-pass function with $|\beta_k| < 1$ for $k = 1, \dots, m$, and $\beta_k = 0$ for $k = m+1, \dots, n$. The poles of $F(v)$ are poles of $\hat{H}(v)$ and the zeros of $F(v) + 1$ are the zeros of $\hat{H}(v)$.

Rewrite $F(v)$ as:

$$F(\beta, v) = v^{-(m-n)} \left(\frac{1 - Rv}{v - R} \right)^q \prod_{k=1}^{\lfloor \frac{n}{2} \rfloor} \frac{1 + s_k v + r_k v^2}{v^2 + s_k v + r_k}$$

where $q = 0$ for n even and $q = 1$ for n odd. For n odd, the parameter vector is $\beta = [s_1, r_1, \dots, s_{\lfloor \frac{n}{2} \rfloor}, r_{\lfloor \frac{n}{2} \rfloor}, R]$ where R is a real pole lying on the real axis in $[-1, \zeta_1]$. By construction, $F(\beta, v) > 0$ in the pass-band.

The gradients of $F(\beta, v)$ with respect to the coefficients, β , are:

$$\begin{aligned}\frac{\partial F(\beta, v)}{\partial s_k} &= \frac{(1 - r_k)v(v^2 - 1)}{(1 + s_kv + r_kv^2)(v^2 + s_kv + r_k)}F(\beta, v) \\ \frac{\partial F(\beta, v)}{\partial r_k} &= \frac{(v^2 - 1)(v^2 + s_kv + 1)}{(1 + s_kv + r_kv^2)(v^2 + s_kv + r_k)}F(\beta, v) \\ \frac{\partial F(\beta, v)}{\partial R} &= \frac{1 - v^2}{(v - R)(1 - Rv)}F(\beta, v)\end{aligned}$$

If Δ_p is specified, then the optimisation problem is to find the stop band attenuation, Δ_s , and $F(\beta, v)$ such that $\hat{H}(v)\hat{H}(\frac{1}{v})$ has $n + 1$ alternating extrema 1 and $1 - \Delta_p$ on (ζ_1, ζ_2) . *Saramäki* points out that, if $\Delta_s \ll 1$, then, in the pass-band:

$$\hat{H}(v)\hat{H}\left(\frac{1}{v}\right) \approx \frac{\Delta_s}{4}F(\beta, v)$$

If $\gamma = \frac{4}{\Delta_s}$, then, in the pass-band, the Newton-Raphson update, $[\Delta\beta, \Delta\gamma]$, is the solution of:

$$F(\beta, v) + \nabla_\beta F(\beta, v)\Delta\beta = (\gamma + \Delta\gamma)\left(1 - \frac{\Delta_p}{2} \pm \frac{\Delta_p}{2}\right)$$

Saramäki suggests that the initial values of β and Δ_s be found by transforming the $n + 1$ frequencies of the pass-band extremal points of an order n Chebyshev Type 1 filter from the z -plane to the v -plane and then solving the corresponding $n + 1$ non-linear polynomial equations for $\hat{H}(v)\hat{H}(\frac{1}{v})$ in the unknowns e_0, \dots, e_{n-1} and Δ_s , with $e_n = 1$:

$$F(v) = v^{-(m-n)} \frac{\sum_{k=0}^n e_{n-k}v^k}{\sum_{k=0}^n e_kv^k}$$

The Octave function *saramakiFBvNewton* implements *Saramäki*'s procedure for $n < m$. The function initialises $F(\beta, v)$ and Δ_s with a polynomial fitted to the $n + 1$ frequencies of the pass-band extremal points. This method is simple but not robust. The Octave script *saramakiFBvNewton_test.m* designs an IIR filter with pass-band edge frequency, $fp = 0.2$, stop-band edge frequency, $fs = 0.35$, pass-band ripple, $dBap = 0.1$, denominator order, $n = 6$, and numerator order, $m = 9$. The resulting stop-band suppression is 127.29dB. Figure K.12 shows the amplitude response of the filter. Figure K.13 shows the pole-zero plot of the filter. The numerator and denominator polynomials are, respectively:

```
n = [ 0.0018065090, 0.0127354024, 0.0426992728, 0.0888119517, ...

```

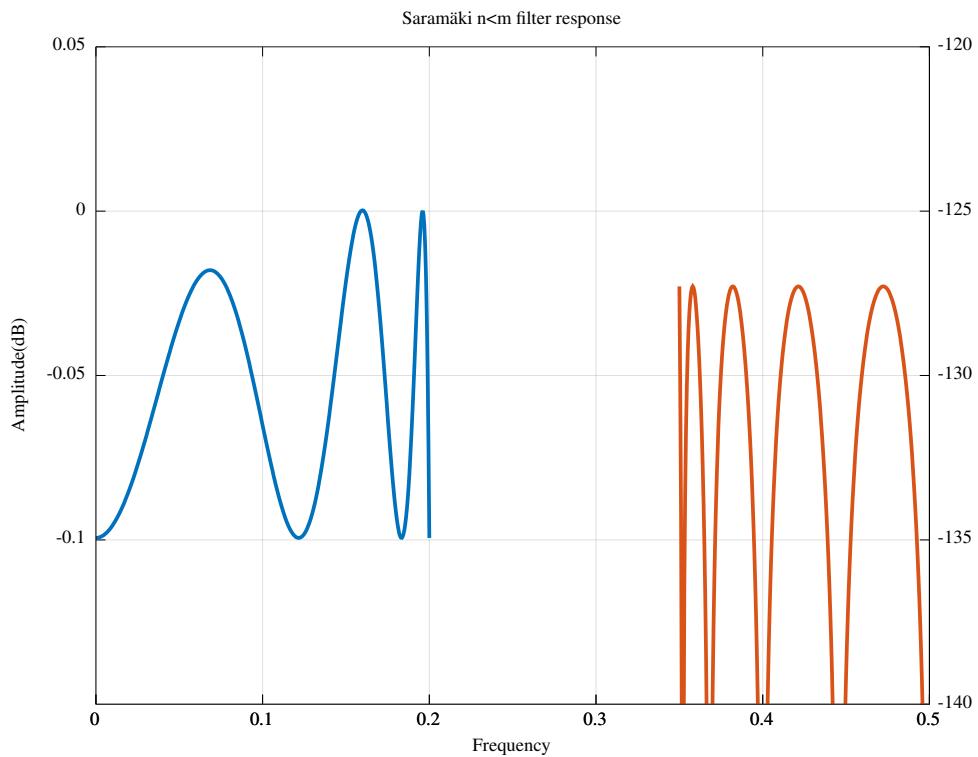

Figure K.12: Amplitude response of an IIR filter with $n = 6$ and $m = 9$, designed with the procedure of Saramäki

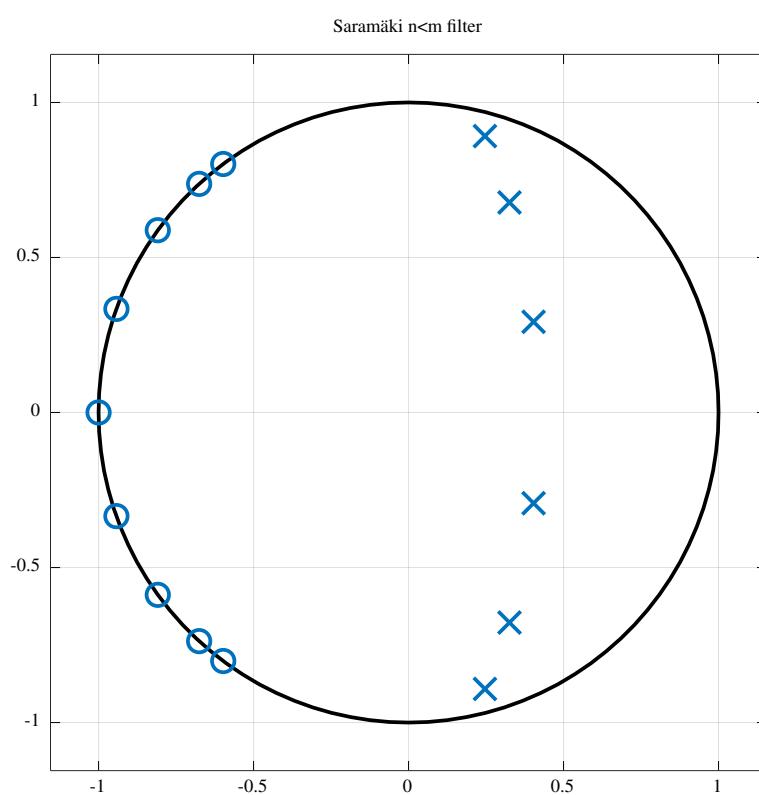

Figure K.13: Pole-zero of an IIR filter with $n = 6$ and $m = 9$, designed with the procedure of Saramäki

K.4.3 Surma-aho and Saramäki method of unconstrained optimisation of an initial IIR filter

The method of *Tarczynski et al.* finds the polynomial transfer function of an initial filter. *Surma-aho* and *Saramäki* [71] describe an algorithm for finding an initial filter with approximately flat group delay in terms of the *gain-pole-zero* description^d of the cascade-form transfer function, reproduced here as Algorithm K.2. The cascade form filter is decomposed into a minimum-phase filter and an all-pass equaliser.

Algorithm K.2 *Surma-aho* and *Saramäki* method for finding an initial IIR filter in *gain-pole-zero* form [71, pp. 958-959]

Step 1: Determine the minimum order of an elliptic filter to meet the given amplitude criteria. Denote the minimum order by n_{min} and set $k = 1$. Then, design an elliptic filter transfer function $H_{min}^k(z)$ such that it satisfies:

Condition 1: $|H_{min}^k(e^{j\omega})|$ oscillates in the stopband $[\omega_s, \pi]$ between δ_s and 0 achieving these values at $n_{min} + 1$ points such that the value at $\omega = \omega_s$ is δ_s . Here, δ_s is the specified stopband ripple.

Condition 2: $|H_{min}^k(e^{j\omega})|$ oscillates in the interval $[0, \Omega_p^k]$ ($\Omega_p^k \geq \omega_p$) between 1 and $1 - \delta_p^k$ achieving these values at $n_{min} + 1$ points such that the value at $\omega = \Omega_p^k$ is $1 - \delta_p^k$. For Candidate I, $\delta_p^k = \delta_p$, with δ_p being the specified passband ripple, whereas the passband region $[0, \Omega_p^k]$ is the widest possible to still meet the given stopband requirements. For Candidate II, $\Omega_p^k = \omega_p$ with ω_p being the specified passband edge, whereas δ_p^k is the smallest passband ripple to still meet the given stopband criteria.

Step 2: Cascade $H_{min}^k(e^{j\omega})$ with a stable all-pass equalizer with a transfer function $H_{all}^k(e^{j\omega})$ of order n_{all} . Determine the adjustable parameters of $H_{all}^k(z)$ and ψ^k such that the maximum deviation of $\arg[H_{all}^k(z) H_{min}^k(z)]$ from the average slope $\phi_{ave}(\omega) = \psi^k \omega$ is minimized in the specified passband region, $[0, \omega_p]$. Let the poles of the all-pass filter be located at $z = z_1^k, z_2^k, \dots, z_{n_{all}}^k$.

Step 3: Set $k = k + 1$. Then, design a minimum-phase filter transfer function $H_{min}^k(z)$ of order $n_{min} + n_{all}$ such that it has n_{all} fixed zeros at $z = z_1^{k-1}, z_2^{k-1}, \dots, z_{n_{all}}^{k-1}$ and it satisfies Condition 1 of Step 1 with the same number of extremal points, that is, $n_{min} + 1$, and Condition 2 of Step 1 with $n_{min} + n_{all} + 1$ extremal points, instead of $n_{min} + 1$ points.

Step 4: Like in Step 2, cascade $H_{min}^k(z)$ with a stable all-pass filter transfer function $H_{all}^k(z)$ of order n_{all} and determine its adjustable parameters and ψ^k such that the maximum of $|\arg[H_{all}^k(z) H_{min}^k(z)] - \psi^k \omega|$ is minimized in $[0, \omega_p]$. Let the poles of the all-pass filter be located at $z = z_1^k, z_2^k, \dots, z_{n_{all}}^k$.

Step 5: If $|z_l^k - z_l^{k-1}| \leq \epsilon$ for $l = 1, 2, \dots, n_{all}$ (ϵ is a small positive number), then stop. In this case, the zeros of the minimum-phase filter being located inside the unit circle and the poles of the all-pass equalizer coincide, reducing the overall order of $H(z) = H_{all}^k(z) H_{min}^k(z)$ from $n_{min} + 2n_{all}$ to $n_{min} + n_{all}$. This filter is the desired initial filter with approximately linear-phase characteristics. Otherwise, go to Step 3.

Saramäki [154] and *Vaidyanathan and Mitra* [113] describe the conditions under which a filter transfer function can be implemented as the sum of two all-pass filters. *Surma-aho* and *Saramäki* modify their algorithm to design a filter composed of two parallel allpass filters, $H(z) = \frac{1}{2}[A(z) + B(z)]$, where the all-pass filter orders differ by 1 and the numerator polynomial of $H(z)$ is a symmetric, even-length FIR filter. Step 3 of Algorithm K.2 is modified so that:

the minimum-phase filter is now of order $n_{min} + 2n_{all}$ and it possesses double zeros at $z = z_1^k, z_2^k, \dots, z_{n_{all}}^k$. Consequently, Condition 2 of Step 1 should be satisfied with $n_{min} + 2n_{all} + 1$ extremal points. In the case of Step 5, the algorithm is terminated when the double zeros of the minimum-phase filter being located inside the unit circle and the poles of the all-pass phase equaliser coincide. This reduces the overall order of $H(z) = H_{all}^k(z) H_{min}^k(z)$ from $n_{min} + 3n_{all}$ to $n_{min} + 2n_{all}$. The third modification in the low-pass case is that n_{min} should be an odd number.

Surma-aho and *Saramäki* [71, Appendix] describe an implementation of Steps 1 and 3 of Algorithm K.2 that is similar to that described above in Section K.4.1, based on *Saramäki* [153].

Algorithm K.2 is initialised with a minimum-phase filter of order n_{min} cascaded with an all-pass phase equaliser of order n_{all} . The squared-magnitude function is constructed with:

$$F(\alpha, v) = \left(\frac{1 - \xi_2 v}{v - \xi_2} \right)^q \times \prod_{k=1}^{\lfloor \frac{n_{min}}{2} \rfloor} \left(\frac{1 - R_k v}{v - R_k} \right)^2 \times \prod_{k=1}^{n_{all}} \left(\frac{1 - v \Gamma_k}{v - \Gamma_k} \right)^p$$

where $n = m = n_{min} + p \times n_{all}$, $q = 0$ if n_{min} is even, $q = 1$ if n_{min} is odd, $p = 2$ if the filter is to be realised as the parallel sum of two all-pass filters and $p = 1$ otherwise. The v -plane poles, Γ_k , are fixed and correspond to the z -plane poles of the all-pass filter. As above, optimising the stop-band peaks results in a new minimum-phase filter with order $n_{min} + p \times n_{all}$. This filter is then equalised with a new all-pass filter of order n_{all} . The procedure is repeated until the poles of the all-pass filter are cancelled by corresponding zeros of the minimum-phase filter. The resulting filter has order $n_{min} + p \times n_{all}$ and approximately linear phase in the pass-band.

^dAlthough, unfortunately, the algorithm requires root-finding of intermediate polynomials.

Low-pass filter example of the Surma-aho and Saramäki method

The Octave script *surmaaho_lowpass_test.m* designs a low-pass filter with approximately flat pass-band delay. The filter specification is:

```
tol=1e-06 % Tolerance on coefficient update vector
nf=1000 % Frequency points across the band
nmin=7 % Minimum-phase filter order
nall=4 % All-pass phase equaliser filter order
fap=0.1 % Pass band amplitude response edge
dBap=0.100000 % Pass band amplitude response ripple
fas=0.125 % Stop band amplitude response edge
dBas=60.000000 % Stop band amplitude response ripple
fpp=0.08 % Initial pass band phase response edge
fpw=0.105 % Wider pass band phase response edge
tp=25 % Nominal pass band group delay
rho=0.968750 % Constraint on allpass pole radius
```

The gain-zero-pole coefficients are:

```
Ux=1,Vx=1,Mx=10,Qx=10,Rx=1
x = [ 0.0011676867, ...
       -1.0000000000, ...
       0.8292402381, ...
       1.0000000000, 1.0000000000, 1.2132533884, ...
       1.2955253028, ...

       0.1658364238, 0.4787379723, 0.3290091013, 0.6074256121, ...
       0.6535665939 ]';
```

Figure K.14 shows the response of the filter. Figure K.15 shows the pole-zero plot of the filter.

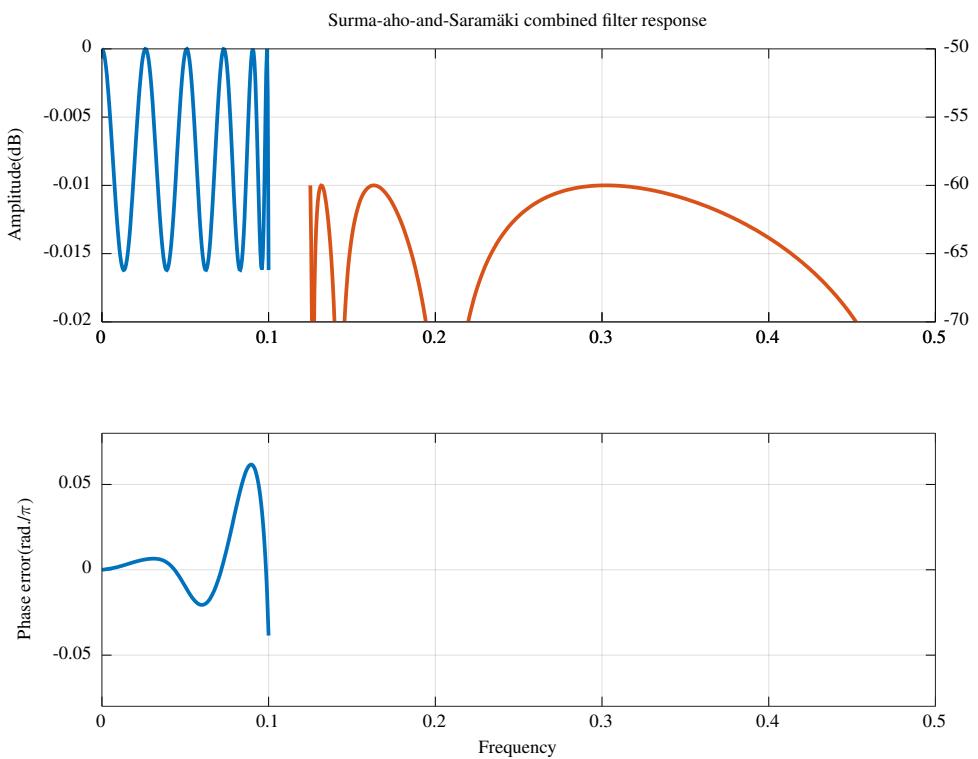

Figure K.14: Response of a low-pass IIR filter with $nmin = 7$ and $nall = 4$, designed with the procedure of Surma-aho and Saramäki

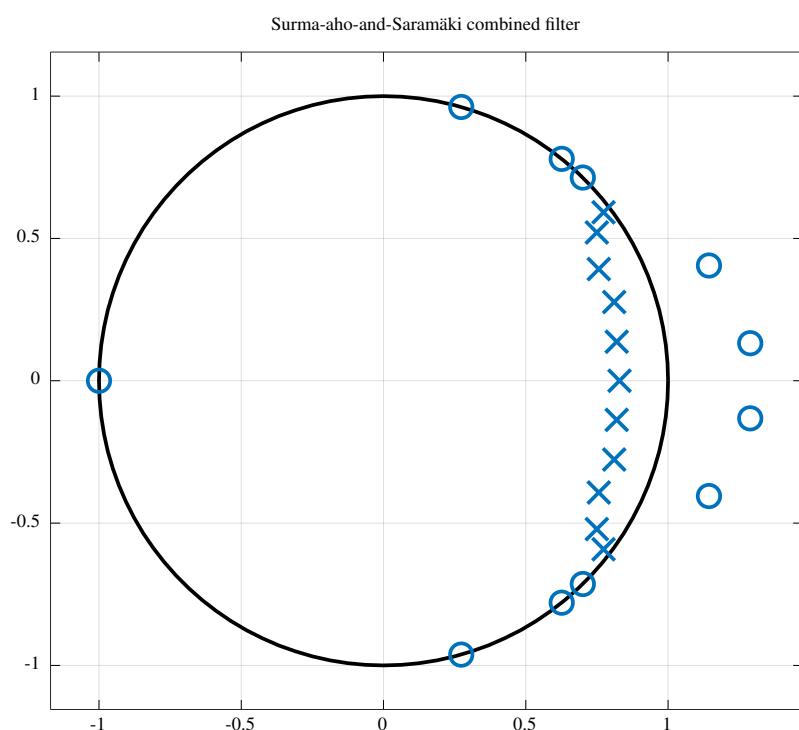

Figure K.15: Pole-zero plot of a low-pass IIR filter with $nmin = 7$ and $nall = 4$, designed with the procedure of Surma-aho and Saramäki

Parallel all-pass low-pass filter example of the Surma-aho and Saramäki method

The Octave script *surmaaho_parallel_allpass_lowpass_test.m* designs a low-pass filter with approximately flat pass-band delay, implemented as the sum of two all-pass filters. The filter specification is:

```
tol=1e-06 % Tolerance on coefficient update vector
nf=2000 % Frequency points across the band
nmin=7 % Minimum-phase filter order
nall=4 % All-pass phase equaliser filter order
fap=0.1 % Pass band amplitude response edge
dBap=0.100000 % Pass band amplitude response ripple
fas=0.125 % Stop band amplitude response edge
dBas=40.000000 % Stop band amplitude response ripple
fpp=0.08 % Initial pass band phase response edge
fpw=0.105 % Wider pass band phase response edge
tp=20 % Nominal pass band group delay
rho=0.968750 % Constraint on allpass pole radius
```

The combined gain-zero-pole coefficients are:

```
Ux=1,Vx=1,Mx=14,Qx=14,Rx=1
x = [ 0.0058222631, ...
       -1.0000000000, ...
       0.7359976363, ...
       0.7374611690, 0.7830853231, 1.0000000000, 1.0000000000, ...
       1.0000000000, 1.2770000541, 1.3560036001, ...
       0.1197954836, 0.4101589300, 0.8762250189, 1.2220444984, ...

Figure K.18: Pole-zero plot of the A1 all-pass low-pass IIR filter designed with the procedure of Surma-aho and Saramäki

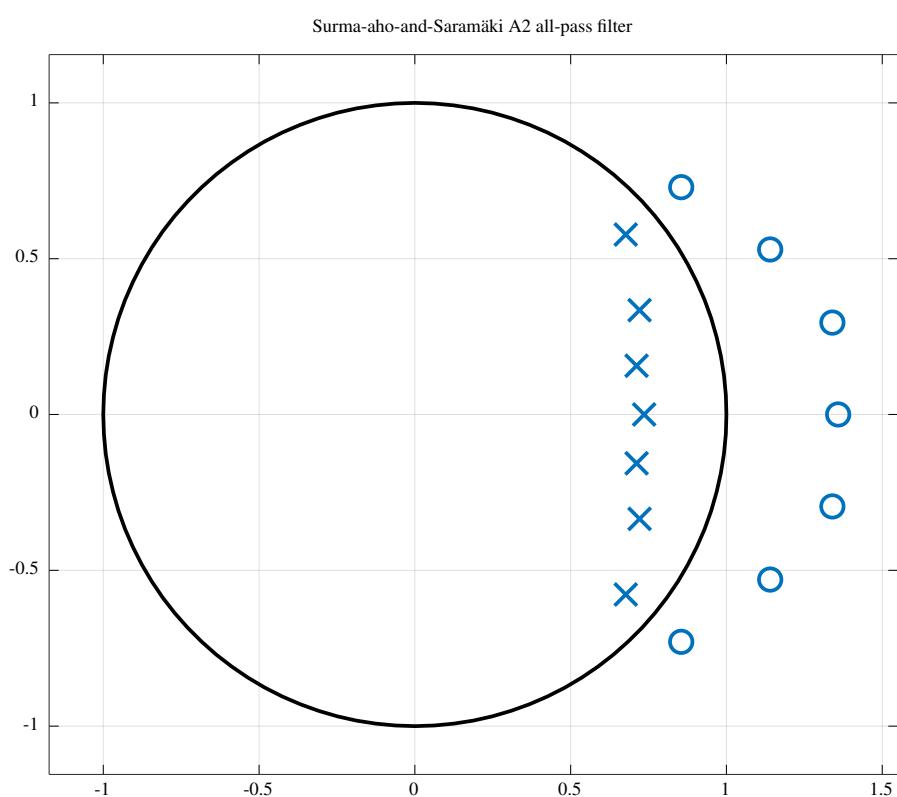

Figure K.19: Pole-zero plot of the A2 all-pass low-pass IIR filter designed with the procedure of Surma-aho and Saramäki

K.5 Johansson and Saramäki design of all-pass complementary IIR filters

Johansson and Saramäki [51, Figure 1] describe a class of all-pass complementary IIR filters “realised as a tapped, cascaded interconnection of identical all-pass subfilters”. A pair of all-pass complementary filters has:

$$H(z) + H_C(z) = H_{ap}(z)$$

where $H_{ap}(z)$ is all-pass. A pair of magnitude complementary filters has:

$$|H(z)| + |H_C(z)| = 1$$

The transfer function of the filter is:

$$H(z) = \sum_{k=0}^M c_k [A_0(z)]^k [A_1(z)]^{M-k}$$

where $A_0(z)$ and $A_1(z)$ are stable all-pass filters, M is even and $c_k = c_{M-k}$ for $k = 0, \dots, M$. The all-pass complementary transfer function is:

$$H_C(z) = [A_0(z) A_1(z)]^{\frac{M}{2}} - H(z)$$

The filter design starts with a pair of all-pass complementary linear-phase FIR filters:

$$\begin{aligned} F(v) &= \sum_{k=0}^M c_k v^{M-k} \\ F_C(v) &= v^{\frac{M}{2}} - F(v) \end{aligned}$$

where:

$$v^{-1} = \frac{A_0(z)}{A_1(z)}$$

is an all-pass frequency transformation. On the unit circle, $z = e^{\omega T}$ and $v = e^{\Omega T}$, where T is the sampling interval. If $\phi_0(\omega T)$ is the phase response of $A_0(z)$ and $\phi_1(\omega T)$ is the phase response of $A_1(z)$, then:

$$\Omega T = \phi_1(\omega T) - \phi_0(\omega T)$$

and the zero-phase response of $F(v)$ is:

$$F_R(\Omega T) = c_{\frac{M}{2}} + 2 \sum_{k=0}^{\frac{M}{2}-1} c_k \cos \left[\left(\frac{M}{2} - k \right) \Omega T \right]$$

The gradients of F_R with respect to the coefficients are:

$$\begin{aligned} \frac{\partial F_R(\Omega T)}{\partial c_k} &= \begin{cases} 2 \cos \left[\left(\frac{M}{2} - k \right) \Omega T \right] & k = 0, \dots, \frac{M}{2} - 1 \\ 1 & k = \frac{M}{2} \end{cases} \\ \frac{\partial F_R(\Omega T)}{\partial \mathbf{a}_0} &= 2 \frac{\partial \phi_0(\omega T)}{\partial \mathbf{a}_0} \sum_{k=0}^{\frac{M}{2}-1} c_k \left(\frac{M}{2} - k \right) \sin \left[\left(\frac{M}{2} - k \right) (\phi_1(\omega T) - \phi_0(\omega T)) \right] \\ \frac{\partial F_R(\Omega T)}{\partial \mathbf{a}_1} &= -2 \frac{\partial \phi_1(\omega T)}{\partial \mathbf{a}_1} \sum_{k=0}^{\frac{M}{2}-1} c_k \left(\frac{M}{2} - k \right) \sin \left[\left(\frac{M}{2} - k \right) (\phi_1(\omega T) - \phi_0(\omega T)) \right] \end{aligned}$$

where \mathbf{a}_0 and \mathbf{a}_1 represent the coefficients of the all-pass filters A_0 and A_1 , respectively.

The diagonal of the Hessian of F_R with respect to the coefficients is:

$$\frac{\partial^2 F_R(\Omega T)}{\partial c_k^2} = 0$$

$$\frac{\partial^2 F_R(\Omega T)}{\partial \mathbf{a}_0^2} = 2 \frac{\partial^2 \phi_0(\omega T)}{\partial \mathbf{a}_0^2} \sum_{k=0}^{\frac{M}{2}-1} c_k \left(\frac{M}{2} - k \right) \sin \left[\left(\frac{M}{2} - k \right) (\phi_1(\omega T) - \phi_0(\omega T)) \right] \dots$$

$$\begin{aligned}
& -2 \left[\frac{\partial \phi_0(\omega T)}{\partial a_0} \right]^2 \sum_{k=0}^{\frac{M}{2}-1} c_k \left(\frac{M}{2} - k \right)^2 \cos \left[\left(\frac{M}{2} - k \right) (\phi_1(\omega T) - \phi_0(\omega T)) \right] \\
\frac{\partial^2 F_R(\Omega T)}{\partial a_1^2} = & -2 \frac{\partial^2 \phi_1(\omega T)}{\partial a_1^2} \sum_{k=0}^{\frac{M}{2}-1} c_k \left(\frac{M}{2} - k \right) \sin \left[\left(\frac{M}{2} - k \right) (\phi_1(\omega T) - \phi_0(\omega T)) \right] \dots \\
& -2 \left[\frac{\partial \phi_1(\omega T)}{\partial a_1} \right]^2 \sum_{k=0}^{\frac{M}{2}-1} c_k \left(\frac{M}{2} - k \right)^2 \cos \left[\left(\frac{M}{2} - k \right) (\phi_1(\omega T) - \phi_0(\omega T)) \right]
\end{aligned}$$

As an example, *Johansson* and *Saramäki* [51, Figure 2] design a band-stop filter with $M = 6$, lower pass-band edge, $\omega_{apl}T = 0.3\pi$, lower stop-band edge, $\omega_{asl}T = 0.4\pi$, upper stop-band edge $\omega_{asu}T = 0.5\pi$ and upper pass-band edge, $\omega_{apu}T = 0.6\pi$. The all-pass transformation phase varies in the range $[0, \Omega_p T]$ across the lower pass-band, in the range $[\pi - \Omega_p T, \pi + \Omega_p T]$ across the stop band and in the range $[2\pi - \Omega_p T, 2\pi]$ across the upper pass-band, where $\Omega_p T = 0.038489$. The specified amplitude peak ripple in each band of the filter is $\delta_p = \delta_s = 0.00001$. The amplitude response of the prototype FIR filter is designed to have pass-band and stop-band widths that correspond to the pass-band peak-to-peak phase and stop-band peak-to-peak phase, respectively, of the all-pass transformation. In other words, the amplitude response of the prototype FIR filter is:

$$\begin{aligned}
1 - \delta_p \leq |F_R(\Omega T)| \leq 1 + \delta_p, \quad \Omega T \in [0, \Omega_p T] \\
|F_R(\Omega T)| \leq \delta_s, \quad \Omega T \in [\pi - \Omega_p T, \pi]
\end{aligned}$$

and the phase response of the all-pass transformation is such that:

$$\begin{aligned}
-\Omega_p T \leq \Omega T \leq \Omega_p T, \quad \omega T \in [0, \omega_{apl}T] \\
\pi - \Omega_p T \leq \Omega T \leq \pi + \Omega_p T, \quad \omega T \in [\omega_{asl}T, \omega_{asu}T] \\
2\pi - \Omega_p T \leq \Omega T \leq 2\pi + \Omega_p T, \quad \omega T \in [\omega_{apu}T, \pi]
\end{aligned}$$

Johansson and *Saramäki* recommend designing the all-pass transformation with the prototype IIR filter:

$$G(z) = \frac{A_0(z) + A_1(z)}{2}$$

having magnitude response:

$$|G(\omega T)| = \left| \cos \frac{\phi_1(\omega T) - \phi_0(\omega T)}{2} \right|$$

and

$$\begin{aligned}
1 - \Delta_p \leq |G(\omega T)| \leq 1 + \Delta_p, \quad \omega T \in [0, \omega_{apl}T] \cup [\omega_{apu}T, \pi] \\
|G(\omega T)| \leq \Delta_s, \quad \omega T \in [\omega_{asu}T, \omega_{asl}T]
\end{aligned}$$

where $\Delta_p = 1 - \cos \frac{\Omega_p T}{2}$ and $\Delta_s = \cos \frac{\pi - \Omega_p T}{2}$.

To design a magnitude complementary pair of filters, $F_R(\Omega T)$ must vary between $1 - \delta_p$ and 1 in the pass-band and between 0 and δ_s in the stop-band. This is achieved by first designing an equi-ripple zero-phase FIR filter, $E_R(\Omega T)$, with pass-band ripple, d_p , and stop-band ripple, d_s , given by:

$$\begin{aligned}
d_p &= \frac{\frac{\delta_p}{2}}{1 - \frac{\delta_p}{2} - \frac{\delta_s}{2}} \\
d_s &= \frac{\frac{\delta_s}{2}}{1 - \frac{\delta_p}{2} - \frac{\delta_s}{2}}
\end{aligned}$$

so that:

$$F_R(\Omega T) = \frac{E_R(\Omega T) + d_s}{1 + d_p + d_s}$$

The Octave script *johansson_cascade_allpass_bandstop_test.m* designs a pair of band-stop and band-pass filters. The band-pass filter is both all-pass and magnitude complementary to the band-stop filter. The band-stop filter specification is:

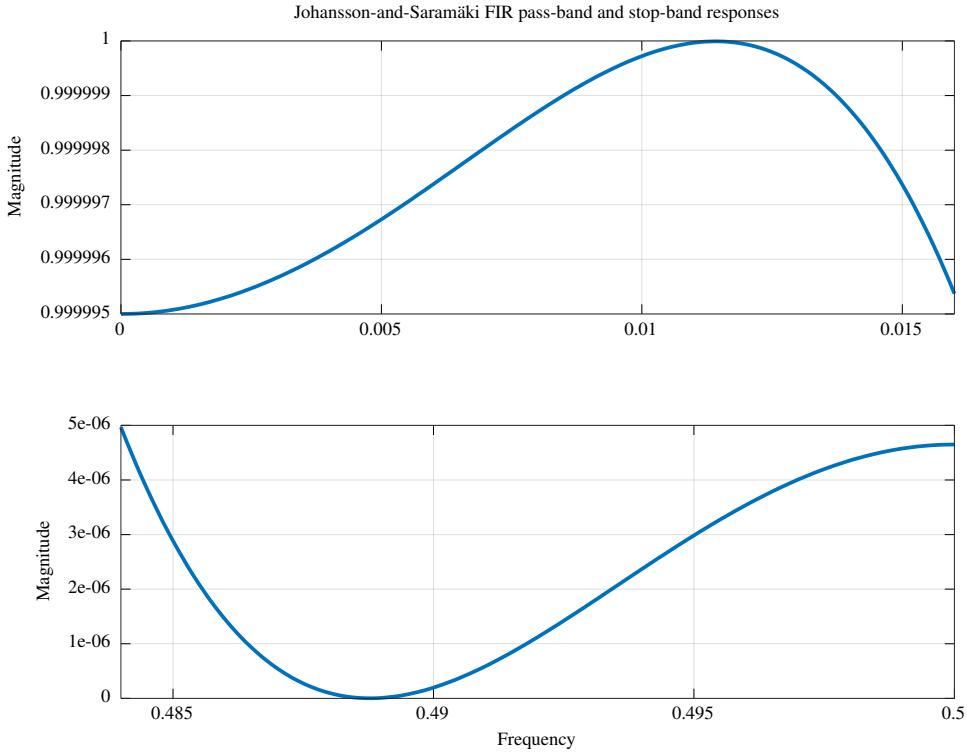

Figure K.20: Pass-band and stop-band responses of the Johannson and Saramäki prototype FIR filter

```

tol=1e-08 % Tolerance on coefficient update vector
ctol=1e-08 % Tolerance on constraints
nf=5000 % Frequency points across the band
M=6 % Prototype FIR filter order
Fap=0.016 % Prototype FIR pass-band amplitude response edge
delta_p=0.000005 % FIR pass-band amplitude response ripple
delta_s=0.000005 % FIR stop-band amplitude response ripple
fapl=0.15 % Pass-band amplitude response lower edge
fasl=0.2 % Stop-band amplitude response lower edge
fasu=0.25 % Stop-band amplitude response upper edge
fapu=0.3 % Pass-band amplitude response upper edge

```

The script designs the prototype FIR filter with the *directFIRsymmetric_slb* and *directFIRsymmetric_socp_mmse* functions. Figure K.20 shows the response of the prototype FIR filter. The prototype FIR filter coefficients are:

```
f1 = [ -0.0314881200, -0.0000085599, 0.2814857078, 0.5000169443, ...
        0.2814857078, -0.0000085599, -0.0314881200 ]';
```

The script designs the prototype IIR filter as the low-pass to band-stop transformation of a parallel all-pass elliptic filter found with the *ellip* function from the Octave-Forge *signal* package. Figure K.21 shows the response of the prototype IIR filter. The prototype IIR filter parallel all-pass polynomial coefficients are:

```
bsA0 = [ 1.0000000000, -0.5650807120, 1.6504676367, -0.4790677580, ...
        0.7284677906 ];
```

```
bsA1 = [ 1.0000000000, -0.2594846657, 0.6383217013 ];
```

Figure K.22 shows the pass-band and stop-band zero-phase response of the band-stop filter. Figure K.23 shows the responses of the complementary filters. Figure K.24 shows the pass-band and stop-band responses of the complementary filters.

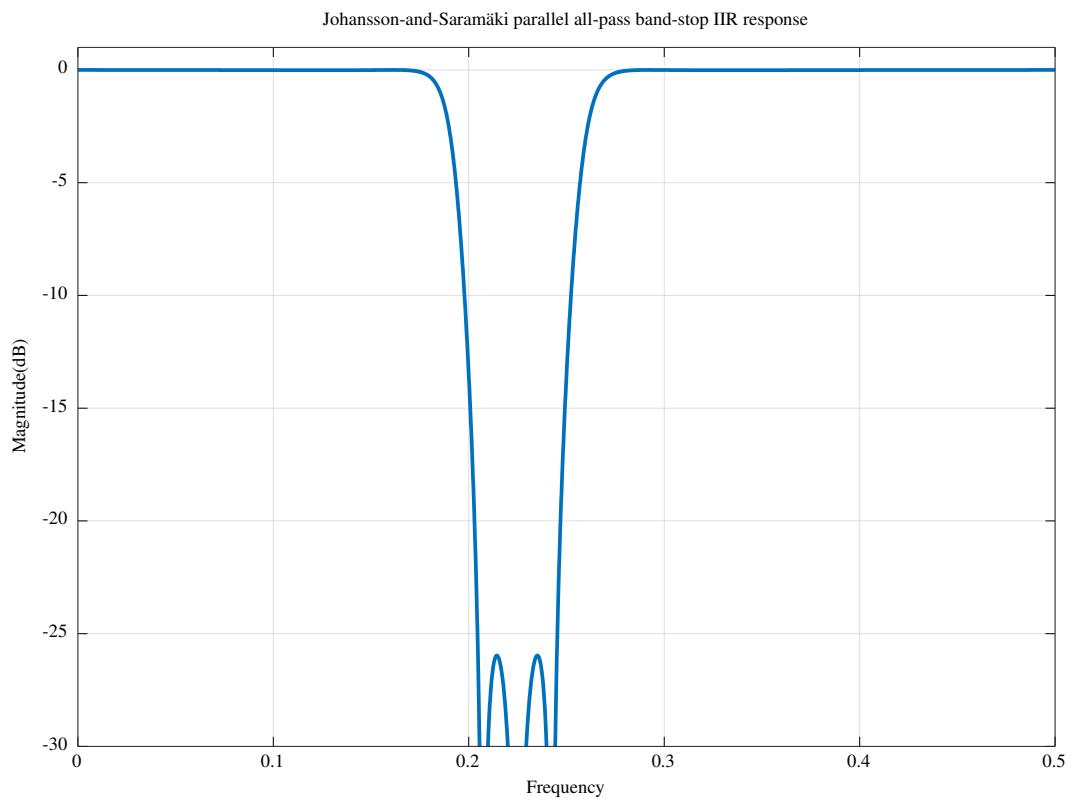

Figure K.21: Response of the Johannson and Saramäki prototype IIR filter

Figure K.23: Responses of the Johannson and Saramäki band-stop complementary IIR filters

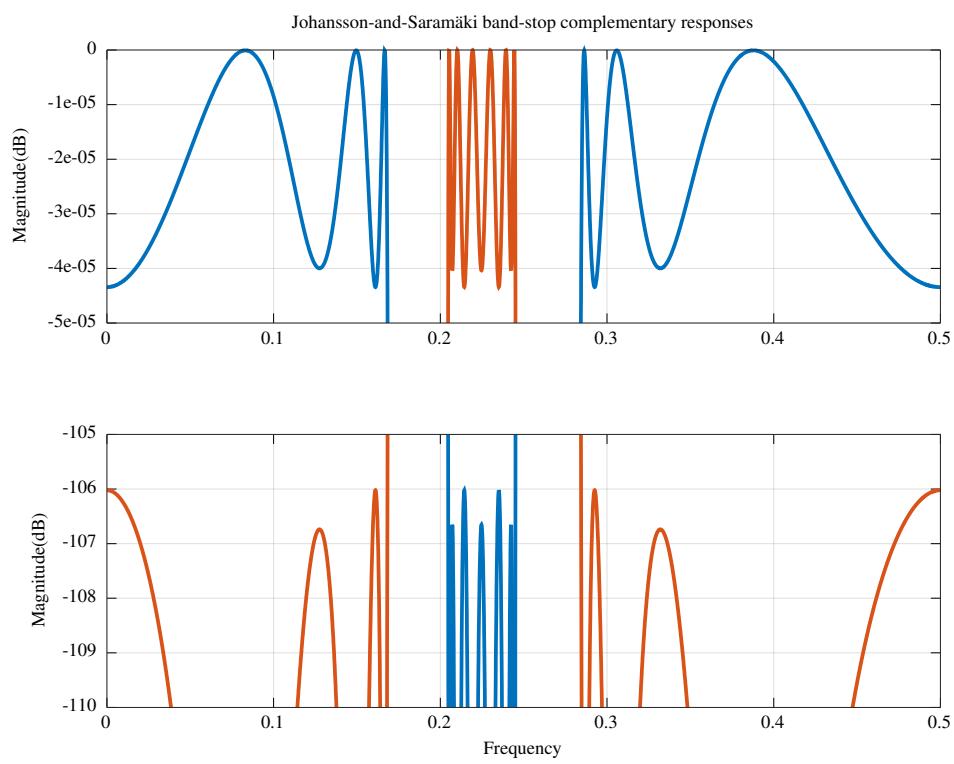

Figure K.24: Pass-band and stop-band responses of the Johannson and Saramäki band-stop complementary IIR filters

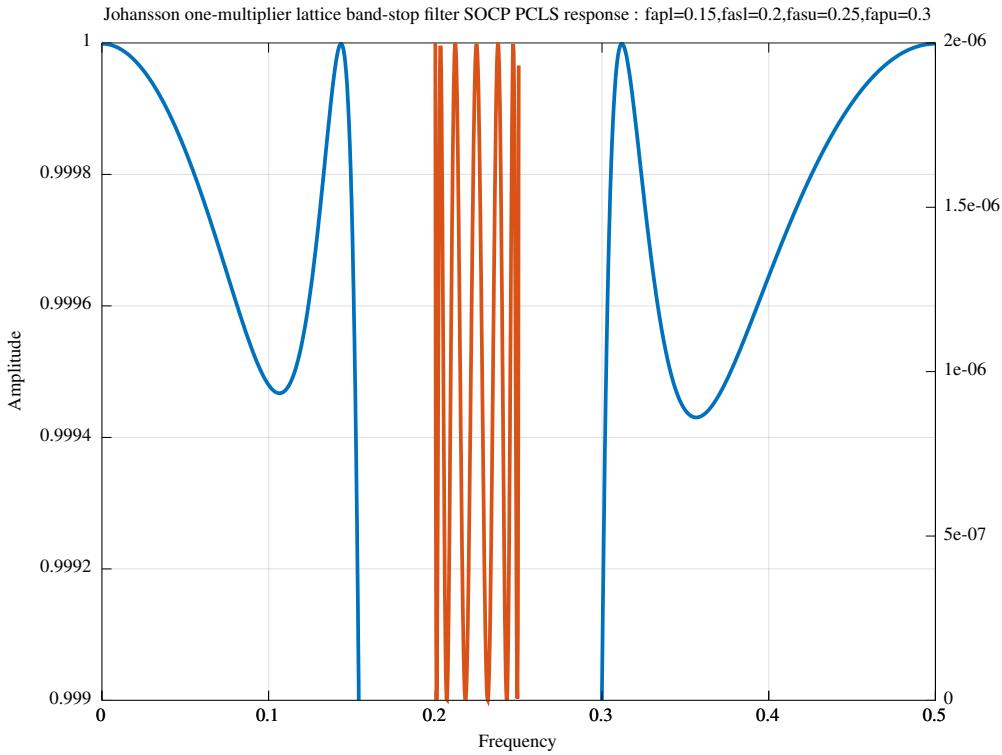

Figure K.25: Responses of the Johansson and Saramäki band-stop filter with PCLS constraints

The Octave script *johanssonOneMlattice_socp_slb_bandstop_test.m* designs a band-stop filter with PCLS constraints. The all-pass filters are implemented as Schur one-multiplier lattice filters. The band-stop filter specification is:

```

tol=1e-06 % Tolerance on coef. update
ctol=2e-08 % Tolerance on constraints
nf=2000 % Frequency points across the band
rho=0.992188 % Constraint on allpass coefficients
fapl=0.15 % Amplitude pass band lower edge
fasl=0.2 % Amplitude stop band lower edge
fasu=0.25 % Amplitude stop band upper edge
fapu=0.3 % Amplitude pass band upper edge
delta_p=0.001 % Amplitude pass band peak ripple
delta_s=2e-06 % Amplitude stop band peak ripple
Wap=1 % Amplitude pass band weight
Was=10 % Amplitude stop band weight

```

The initial band-stop filter is that designed by the Octave script *johansson_cascade_allpass_bandstop_test.m*. The resulting band-stop filter coefficients are:

```

f = [ -0.0278384479,    0.0071177162,    0.2778376394,    0.4857649475, ...
      0.2778376394,    0.0071177162,   -0.0278384479 ]';

```

```

k0 = [ -0.1820024209,    0.8447713007,   -0.1350137135,    0.6598419792 ]';

```

```

k1 = [ -0.1575683846,    0.5437545726 ]';

```

Figure K.25 shows the pass-band and stop-band responses of the filter.

The Octave script *branch_bound_johanssonOneMlattice_bandstop_test.m* designs a band-stop filter having 3-signed-digit 16-bit coefficients with the *branch-and-bound* algorithm (see Chapter 14). The all-pass filters are implemented as Schur one-multiplier lattice filters. The band-stop filter specification is:

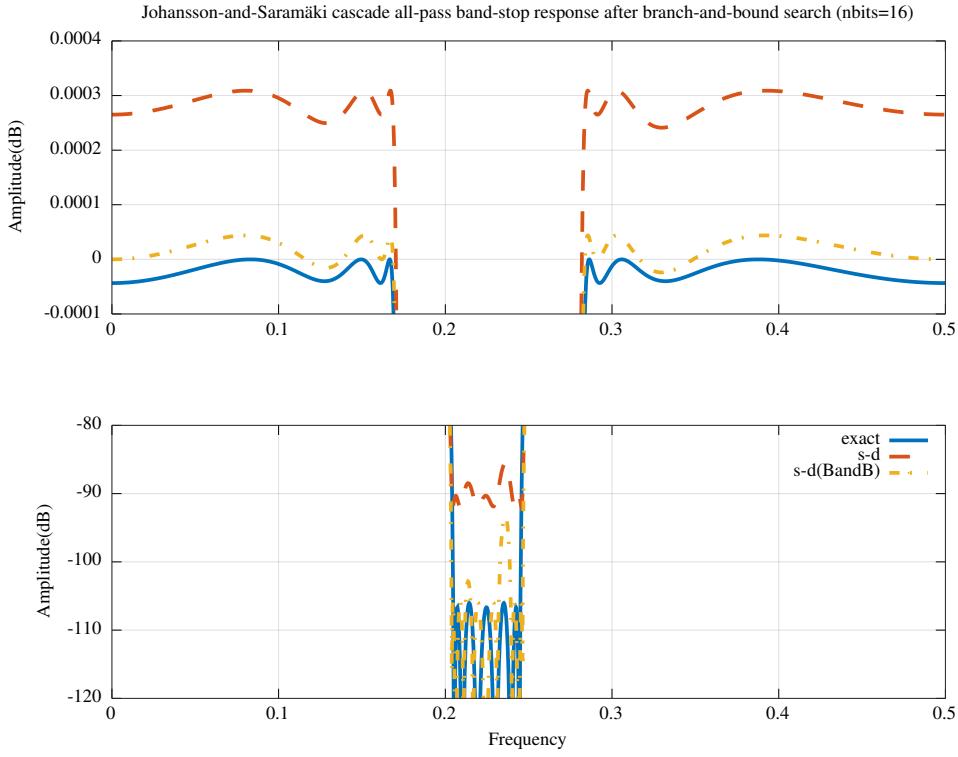

Figure K.26: Responses of the Johannsson and Saramäki band-stop filter with 3-signed-digit, 16-bit coefficients designed with the *branch-and-bound* algorithm

```

nbits=16 % Coefficient bits
ndigits=3 % Coefficient signed-digits
nf=5000 % Frequency points across the band
fapl=0.15 % Amplitude pass band lower edge
fasl=0.2 % Amplitude stop band lower edge
fasu=0.25 % Amplitude stop band upper edge
fapu=0.3 % Amplitude pass band upper edge
Wap=1 % Amplitude pass band weight
Was=1 % Amplitude stop band weight

```

The initial band-stop filter is that designed by the Octave script *johansson_cascade_allpass_bandstop_test.m*. The resulting band-stop filter 3-signed-digit, 16-bit coefficients are:

```

f_min = [      -1032,          0,       9224,      16384, ...
           9224,          0,     -1032 ] '/32768;

k0_min = [      -5632,      29696,     -4736,      24064 ] '/32768;

k1_min = [     -5184,     20992 ] '/32768;

```

Figure K.26 shows the pass-band and stop-band responses of the filter.

Appendix L

Design of FIR digital filter transfer functions

This chapter reviews methods of designing FIR digital filter transfer functions.

L.1 Low passband sensitivity FIR lattice filters

L.1.1 Lattice decomposition of an FIR digital filter

Vaidyanathan [112] describes the design of low passband sensitivity FIR digital filters based on the lattice decomposition of a bounded-real FIR filter, $H(z)$, such that $|H(e^{j\omega})| \leq 1$, and the bounded-real complementary filter, $G(z)$, with $|H(e^{j\omega})|^2 + |G(e^{j\omega})|^2 = 1$. Assume that $H_{m+1}(z)$ and $G_{m+1}(z)$ are complementary FIR filter transfer function polynomials of order $m+1$:

$$H_{m+1}(z) = \sum_{n=0}^{m+1} h_{m+1,n} z^{-n} \quad (\text{L.1})$$

$$G_{m+1}(z) = \sum_{n=0}^{m+1} g_{m+1,n} z^{-n} \quad (\text{L.2})$$

and write $\tilde{H}_{m+1}(z) = H_{m+1}^T(z^{-1})$, where T denotes transpose.

$A_{m+1}(z) = [H_{m+1}(z) \ G_{m+1}(z)]^T$ represents the corresponding all-pass filter:

$$\tilde{A}_{m+1}(z) A_{m+1}(z) = 1$$

or

$$\tilde{H}_{m+1}(z) H_{m+1}(z) + \tilde{G}_{m+1}(z) G_{m+1}(z) = 1 \quad (\text{L.3})$$

After expanding Equation L.3 with Equations L.1 and L.2, the term in z^{m+1} is, by inspection:

$$h_{m+1,m+1} h_{m+1,0} + g_{m+1,m+1} g_{m+1,0} = 0 \quad (\text{L.4})$$

If $h_{m+1,m+1} = 0$ then either $g_{m+1,m+1} = 0$, in which case the current order reduction step is not necessary, or $g_{m+1,0} = 0$ in which case:

$$\begin{aligned} H_m(z) &= H_{m+1}(z) \\ G_m(z) &= zG_{m+1}(z) \end{aligned}$$

For the general case, Vaidyanathan derives the following order reduction of $A_{m+1}(z)$ to $A_m(z)$:

$$\begin{bmatrix} H_m(z) \\ G_m(z) \end{bmatrix} = \begin{bmatrix} k_{m+1} & \hat{k}_{m+1} \\ -\hat{k}_{m+1}z & k_{m+1}z \end{bmatrix} \begin{bmatrix} H_{m+1}(z) \\ G_{m+1}(z) \end{bmatrix}$$

where [112, Equations 13 and 14]:

$$k_{m+1} = \frac{-g_{m+1,m+1}}{\sqrt{h_{m+1,m+1}^2 + g_{m+1,m+1}^2}}, \hat{k}_{m+1} = \frac{h_{m+1,m+1}}{\sqrt{h_{m+1,m+1}^2 + g_{m+1,m+1}^2}} \quad (\text{L.5})$$

or [112, Equation 23]:

$$k_{m+1} = \frac{h_{m+1,0}}{\sqrt{h_{m+1,0}^2 + g_{m+1,0}^2}}, \hat{k}_{m+1} = \frac{g_{m+1,0}}{\sqrt{h_{m+1,0}^2 + g_{m+1,0}^2}} \quad (\text{L.6})$$

The final order reduction step is:

$$\begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} k_0 & \hat{k}_0 \\ -\hat{k}_0 z & k_0 z \end{bmatrix} \begin{bmatrix} H_0(z) \\ G_0(z) \end{bmatrix}$$

The $m+1$ 'th lattice filter section is related to the m 'th section by:

$$A_{m+1}(z) = \tau_{m+1}(z) A_m(z)$$

where

$$\tau_{m+1}(z) = \begin{bmatrix} k_{m+1} & -\hat{k}_{m+1} z^{-1} \\ \hat{k}_{m+1} & k_{m+1} z^{-1} \end{bmatrix}$$

$A_m(z)$ also represents an allpass filter since $\tilde{\tau}_{m+1}(z) \tau_{m+1}(z) = I$ and:

$$\begin{aligned} I &= \tilde{A}_{m+1}(z) A_{m+1}(z) \\ &= \tilde{A}_m(z) \tilde{\tau}_{m+1}(z) \tau_{m+1}(z) A_m(z) \\ &= \tilde{A}_m(z) A_m(z) \end{aligned}$$

The Octave function *complementaryFIRdecomp.m* implements FIR lattice decomposition with filter order reduction by Equation L.6. (I found that Equation L.6 has better numerical performance than Equation L.5).

L.1.2 Finite-wordlength properties of the lattice FIR filter

Section L.1.3 shows that transfer function of the complementary FIR lattice is the result of N orthogonal transformations:

$$\begin{bmatrix} H_N & G_N \end{bmatrix}^T = \tau_N \cdots \tau_1 \begin{bmatrix} H_0 & G_0 \end{bmatrix}^T$$

where the τ_m are orthogonal matrixes:

$$\tau_m(z) = \begin{bmatrix} k_m & -\hat{k}_m z^{-1} \\ \hat{k}_m & k_m z^{-1} \end{bmatrix}$$

Vaidyanathan [112][Section VII] shows that this determines the finite-wordlength properties of the lattice FIR filter:

1. The noise gain from the inputs to the combined complementary outputs of the filter is N
2. The multiplier inputs are scaled since if $H_0^2 + G_0^2 = 1$ then $H_m^2 + G_m^2 = 1$. (Section 3.3.3 describes state scaling).
3. The coefficient sensitivities to k_m are:

$$\frac{\partial}{\partial k_m} \begin{bmatrix} H_N & G_N \end{bmatrix}^T = \tau_N \cdots \tau_{m+1} \begin{bmatrix} 1 & 0 \\ 0 & z^{-1} \end{bmatrix} \tau_{m-1} \cdots \tau_1 \begin{bmatrix} H_0 & G_0 \end{bmatrix}^T$$

so the coefficient sensitivities of the FIR lattice are bounded:

$$\left| \frac{\partial H_N}{\partial k_m} \right|^2 + \left| \frac{\partial G_N}{\partial k_m} \right|^2 = 1$$

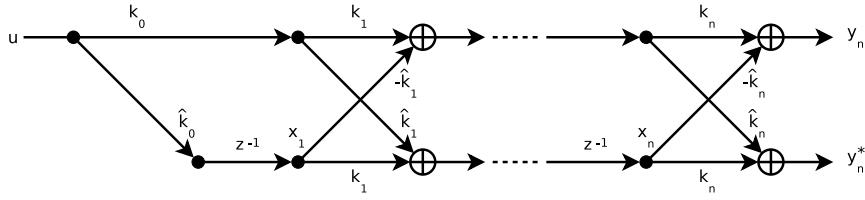

Figure L.1: Structure of the complementary FIR lattice filter (see *Vaidyanathan* [112, Figure 3])

Algorithm L.1 Construction of a state variable description of the complementary FIR lattice filter

```

 $y_0^* = \hat{k}_0 u$ 
 $y_0 = k_0 u$ 
for  $n = 1, \dots, N$  do
     $x'_n = y_{n-1}^*$ 
     $y_n^* = \hat{k}_n y_{n-1} + k_n x_n$ 
     $y_n = k_n y_{n-1} - \hat{k}_n x_n$ 
end for
 $y = y_N$ 

```

L.1.3 State variable description of the complementary FIR lattice filter

Figure L.1 (see Figure 3 of *Vaidyanathan* [112]) shows the complementary FIR lattice structure.

For convenience, call x'_n the input to state x_n of the n -th section, y_n^* the lower output of the n -th section and y_n the upper output of the n -th section. Construction of the state variable description of the complementary FIR lattice is summarised in Algorithm L.1.

As shown in Section 1.12.2, the state variable description can be expressed as a series of matrix multiplications linking the input and state outputs to the output and the next state inputs.

$$\begin{bmatrix} y_0^* \\ y_0 \\ x_1 \\ x_2 \\ \vdots \\ x_N \end{bmatrix} = \begin{bmatrix} 0 & \cdots & \cdots & 0 & \hat{k}_0 \\ 0 & \cdots & \cdots & 0 & k_0 \\ 1 & \cdots & \cdots & 0 & 0 \\ \vdots & \ddots & & & \vdots \\ \vdots & & \ddots & & \vdots \\ 0 & \cdots & & 1 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_N \\ u \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ y_1^* \\ y_1 \\ x_2 \\ \vdots \\ x_N \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & \cdots & 0 \\ 0 & \hat{k}_1 & k_1 & 0 & \cdots & 0 \\ 0 & k_1 & -\hat{k}_1 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 1 & \cdots & 0 \\ \vdots & & & \ddots & & \vdots \\ 0 & \cdots & & \cdots & 1 \end{bmatrix} \begin{bmatrix} y_0^* \\ y_0 \\ x_1 \\ x_2 \\ \vdots \\ x_N \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ x'_2 \\ y_2^* \\ y_2 \\ x_3 \\ \vdots \\ x_N \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 1 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & \hat{k}_2 & k_2 & 0 & \cdots & 0 \\ 0 & 0 & k_2 & -\hat{k}_2 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 0 & 1 & \cdots & 0 \\ \vdots & & & & \ddots & & \vdots \\ 0 & \cdots & & \cdots & \cdots & 1 \end{bmatrix} \begin{bmatrix} x'_1 \\ y_1^* \\ y_1 \\ x_2 \\ x_3 \\ \vdots \\ x_N \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ \vdots \\ x'_{N-1} \\ y_{N-1}^* \\ y_{N-1} \\ x_N \end{bmatrix} = \begin{bmatrix} 1 & \cdots & & \cdots & 0 \\ \vdots & \ddots & & & \vdots \\ 0 & \cdots & 1 & 0 & 0 & 0 \\ 0 & \cdots & 0 & \hat{k}_{N-1} & k_{N-1} & 0 \\ 0 & \cdots & 0 & k_{N-1} & -\hat{k}_{N-1} & 0 \\ 0 & \cdots & 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x'_1 \\ \vdots \\ x'_{N-2} \\ y_{N-2}^* \\ y_{N-2} \\ x_{N-1} \\ x_N \end{bmatrix}$$

$$\begin{bmatrix} x'_1 \\ \vdots \\ x'_N \\ y_N^* \\ y_N \end{bmatrix} = \begin{bmatrix} 1 & \cdots & \cdots & 0 \\ \vdots & \ddots & & \vdots \\ 0 & \cdots & 1 & 0 & 0 \\ 0 & \cdots & 0 & \hat{k}_N & k_N \\ 0 & \cdots & 0 & k_N & -\hat{k}_N \end{bmatrix} \begin{bmatrix} x'_1 \\ \vdots \\ y_{N-1}^* \\ y_{N-1} \\ x_N \end{bmatrix}$$

The Octave function `complementaryFIRlattice2Abcd` returns the state variable description of a complementary FIR lattice filter.

L.1.4 Design of the complementary FIR digital filter

The previous sections of this chapter assume that the complementary FIR filter is known. This section shows two methods for finding that filter. The first, *Orchard and Willson's* Newton-Raphson solution [49], is simpler and more accurate than the cepstral method of *Mian and Nainer* [41].

Orchard and Willson's Newton-Raphson solution

If an order N FIR filter $H(z)$ is bounded-real then $|H(e^{i\omega})| \leq 1$. The magnitude-squared complementary filter $1 - H^\dagger(z)H(z)$, where \dagger means *conjugate*, is linear-phase and has double zeros on the unit-circle when $|H(e^{i\omega})| = 1$. *Orchard and Willson* [49] find the minimum-phase spectral factor of the magnitude-squared complementary filter by a Newton-Raphson solution of the non-linear system of equations linking the coefficients of the two filters. They demonstrate that the Newton-Raphson recursion converges linearly when the linear phase filter being factored has zeros on the unit circle. *Orchard and Willson* show a MATLAB (ie: Octave) implementation, `minphase.m`, in Appendix A of the reference.

Orchard and Willson justify their method with the following example. Firstly, they define a short linear phase FIR filter:

$$H(z) = z^{-3} [h_0 + h_1(z + z^{-1}) + h_2(z^2 + z^{-2}) + h_3(z^3 + z^{-3})]$$

$H(z)$ is assumed to be the product of a minimum phase factor:

$$F_1(z) = a_0 + a_1z^{-1} + a_2z^{-2} + a_3z^{-3}$$

and the corresponding maximum phase factor:

$$\begin{aligned} F_2(z) &= z^{-3}F_1(z^{-1}) \\ &= a_3 + a_2z^{-1} + a_1z^{-2} + a_0z^{-3} \end{aligned}$$

Equating the coefficients of terms on either side of the equality sign in $H(z) = F_1(z)F_2(z)$ gives the system of non-linear equations:

$$\begin{aligned} h_0 &= a_0^2 + a_1^2 + a_2^2 + a_3^2 \\ h_1 &= a_0a_1 + a_1a_2 + a_2a_3 \\ h_2 &= a_1a_3 + a_0a_2 \\ h_3 &= a_0a_3 \end{aligned}$$

The Newton-Raphson method solves a system of equations $f(\mathbf{a}) = 0$ by successive approximations:

$$f(\mathbf{a}_k) + J(\mathbf{a}_k)[\mathbf{a}_{k+1} - \mathbf{a}_k] = 0$$

or:

$$\mathbf{a}_{k+1} = \mathbf{a}_k - J^{-1}(\mathbf{a}_k)f(\mathbf{a}_k)$$

where $J(\mathbf{a})$ is the Jacobian matrix of $f(\mathbf{a})$.

In this case:

$$f(\mathbf{a}) = \begin{bmatrix} h_0 - a_0^2 - a_1^2 - a_2^2 - a_3^2 \\ h_1 - a_0a_1 - a_1a_2 - a_2a_3 \\ h_2 - a_1a_3 - a_0a_2 \\ h_3 - a_0a_3 \end{bmatrix}$$

$$J(\mathbf{a}) = - \begin{bmatrix} 2a_0 & 2a_1 & 2a_2 & 2a_3 \\ a_1 & a_2 + a_0 & a_3 + a_1 & a_2 \\ a_2 & a_3 & a_0 & a_1 \\ a_3 & 0 & 0 & a_0 \end{bmatrix}$$

$$= - \begin{bmatrix} a_0 & a_1 & a_2 & a_3 \\ a_1 & a_2 & a_3 & 0 \\ a_2 & a_3 & 0 & 0 \\ a_3 & 0 & 0 & 0 \end{bmatrix} - \begin{bmatrix} a_0 & a_1 & a_2 & a_3 \\ 0 & a_0 & a_1 & a_2 \\ 0 & 0 & a_0 & a_1 \\ 0 & 0 & 0 & a_0 \end{bmatrix}$$

The function *minphase.m* solves for the coefficient update, $\mathbf{d}_{k+1} = \mathbf{a}_{k+1} - \mathbf{a}_k$, by matrix left division. The C++ file *minphase.cc* implements the *minphase* algorithm as an *oct-file* using the *Eigen* [46] C++ template library with *long double* matrix elements.

I experimented with the Octave-Forge *optim* package *leasqr* function, an implementation of Levenberg-Marquardt non-linear optimisation. I found that *leasqr* needed to be initialised with the *minphase* solution and did not improve that solution by more than a few machine *epsilon*.

Mian and Nainer's cepstral method

Mian and Nainer [41] describe finding the minimum-phase spectral factor of the magnitude-squared complementary response by calculating the cepstrum of that response along a z -plane contour slightly off the unit circle. This contour reduces aliasing of the cepstrum due to the response zeros that lie on the unit circle. See Appendix A for a review of the complex variables theory used in this section.

Properties of the cepstrum Firstly, recall that the z -transform of a real sequence, \mathbf{x} , is

$$X(z) = \sum_{n=-\infty}^{\infty} x(n) z^{-n}$$

and that the inverse z -transform is

$$x(n) = \frac{1}{2\pi i} \oint_C X(z) z^{n-1} dz$$

where the contour, C , is centred on the origin and lies within the region of convergence. Cauchy's integral lemma is

$$\oint_C z^n dz = \begin{cases} 2\pi i & n = -1 \\ 0 & n \neq -1, \text{ integral} \end{cases}$$

The *complex cepstrum* is the inverse z -transform of $\hat{X}(z) = \log X(z) = \log |X(z)| + i \arg X(z)$ on the unit circle:

$$\hat{x}(n) = \frac{1}{2\pi i} \oint_C \log X(z) z^{n-1} dz$$

The *real cepstrum* is the inverse z -transform of $\log |X(z)|$ on the unit circle.

For example, suppose $X(z) = K(1 - az^{-1})(1 - bz)$, where $|a|, |b| < 1$. By Cauchy's integral lemma and the definition of the z -transform, $K = X(0) = x(0)$. The complex cepstrum is:

$$\hat{x}(n) = \frac{1}{2\pi i} \oint_C [\log K + \log(1 - az^{-1}) + \log(1 - bz)] z^{n-1} dz$$

Applying Cauchy's integral lemma and the series expansion $\log(1 + z) = \sum_{k=1}^{\infty} (-1)^{k+1} \frac{z^k}{k}$, where $|z| < 1$:

$$\hat{x}(n) = \begin{cases} -\frac{a^n}{n}, & n > 0 \\ \log K, & n = 0 \\ \frac{b^n}{n}, & n < 0 \end{cases}$$

This example demonstrates the motivation for using the cepstrum to find a minimum-phase spectral factor: if \mathbf{x} is minimum-phase then the cepstrum, $\hat{\mathbf{x}}$, is causal. Similarly, if \mathbf{x} is maximum-phase then the cepstrum is anti-causal.

The complex cepstrum is related to the original sequence, x , by a recursion. In the z-domain:

$$\begin{aligned}\frac{d}{dz} \hat{X}(z) &= \frac{1}{X(z)} \frac{d}{dz} X(z) \\ \left[-z \frac{d}{dz} \hat{X}(z) \right] X(z) &= -z \frac{d}{dz} X(z)\end{aligned}$$

So, in the time domain:

$$n\hat{x}(n) * x(n) = nx(n)$$

In other words:

$$x(n) = \begin{cases} e^{\hat{x}(0)} & n = 0 \\ \sum_{k=-\infty}^{\infty} \frac{k}{n} \hat{x}(n) x(n-k) & n \neq 0 \end{cases} \quad (\text{L.7})$$

Using the cepstrum to find the minimum-phase spectral factor Given a bounded-real transfer function $H(z)$ of order N , the z-transform of the magnitude-squared complementary filter is:

$$F(z) = 1 - |H(z)|^2 = 1 - H^\dagger(z) H(z)$$

where \dagger means *conjugate*. By construction, $F(z)$ is real, even, $0 \leq F(e^{j\omega}) \leq 1$ and any zeros of $F(z)$ on the unit circle are double zeros. If $F(z)$ has zeros on the unit circle, then $\hat{F}(z) = \log F(z)$ is not defined at those zeros. However we can make use of the z-transform

$$X(\alpha z) = \sum_{n=-\infty}^{\infty} \alpha^{-n} x(n) z^{-n}$$

to calculate the cepstrum over a contour that is slightly outside the unit circle. In this case, $F(\alpha z)$ is real and even so that, by construction, the cepstrum, $\hat{f}_\alpha(n)$, is real and even. Therefore the causal part of the cepstrum is

$$\hat{h}_\alpha(n) = \begin{cases} \frac{\hat{f}_\alpha(n)}{2} & n = 0 \\ \hat{f}_\alpha(n) & n > 0 \\ 0 & n < 0 \end{cases}$$

and the impulse response of the minimum-phase spectral factor is $h(n) = \alpha^n h_\alpha(n)$ where $h_\alpha(n)$ is found from the recursion given above in Equation L.7. Unfortunately this method fails if $F(\alpha z)$ is not positive.

A simple example Here is *Octave* code for a simple example recovering the minimum-phase spectral factor from a magnitude-squared filter with double zeros on the unit circle^a:

```
% Construct a minimum phase example with zeros on the unit circle
a1=[1 -1 0.5];a2=[1 -0.5];a3=[1 0 0.81];a4=[1 -1];a5=[1 -sqrt(2) 1];
a=conv(conv(conv(conv(a1,a2),a3),a4),a5);
% Construct the squared-magnitude filter for a contour of |z|=alpha
Na=length(a)-1;
alpha=1.05;
aalpha=a.* (alpha.^[0:-1:-Na]);
asq=conv(fliplr(aalpha),aalpha);
% The zero-phase squared-magnitude frequency response is real, positive and even
Hasq=freqz(asq,[zeros(1,Na) 1],4096,"whole");
Hasq=real(Hasq);
% The cepstrum is real and even
hhatasq=ifft(log(Hasq));
hhatasq=real(hhatasq(:)');
% Use the causal part of the cepstrum
ha=zeros(1,Na+1);
ha(1)=exp(hhatasq(1)/2);
for n=2:(Na+1)
    ha(n)=sum([1:(n-1)].*hhatasq(2:n).*fliplr(ha(1:(n-1))))/(n-1);
endfor
% Recover the original minimum-phase impulse response
h=ha.* (alpha.^[0:Na]);
```

^aNote that the Octave convention is that the polynomial $[a \ b \ c]$ corresponds to the z-transform $a + bz^{-1} + cz^{-2}$ so the zero-phase squared-magnitude response calculated by *freqz* must be scaled by a denominator polynomial z^{-N} .

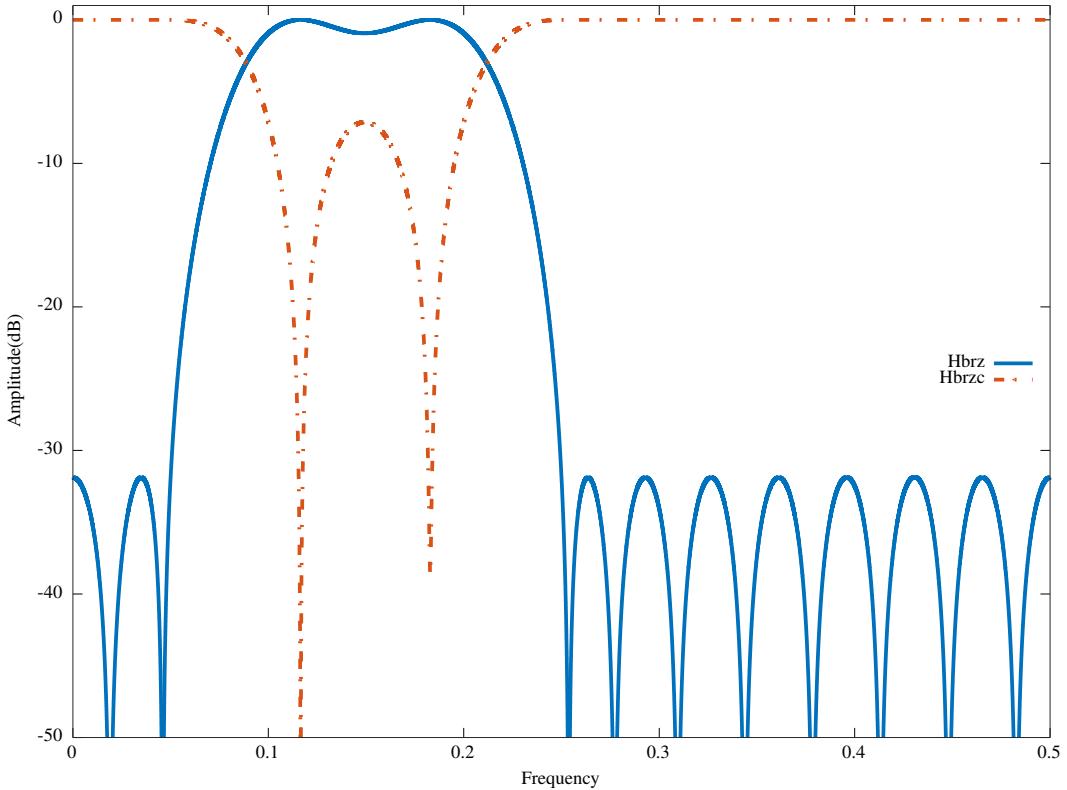

Figure L.2: Amplitude responses of the FIR band-pass filter and the minimum-phase complementary filter found with *Orchard* and *Willson*'s Newton-Raphson method

Example: the minium-phase complementary filter of an FIR bandpass filter The Octave script *minphase_test.m* compares the use of *Orchard* and *Willson*'s Newton-Raphson method with the cepstral method of *Mian* and *Nainer*. The script uses both methods to find the minimum-phase complementary filter for an FIR bandpass filter designed with the Octave *remez* function. The combined response of the bandpass filter and the complementary filter found by the Newton-Raphson method is allpass to within an order of magnitude of the machine precision ($\text{eps} = 2.2204e-16$). The bandpass and complementary filter magnitude responses are shown in Figure L.2.

Unfortunately, in the case of the cepstral method, $F(\alpha z)$ with $\alpha \approx 1.15$ is real and even but not positive. Fortuitously, when using $\alpha = 1$ with a long FFT the sampling grid did not include the filter zeros. Response aliasing due to the discontinuities in $\log F(\alpha z)$ gave a result that was less accurate than that obtained with *minphase.m* but was still acceptable. The combined amplitude response found with the cepstral method is shown in Figure L.3.

L.2 Constrained least-squared error optimisation of FIR digital filters

This section describes the design of constrained symmetric even-order FIR filters by the method of Lagrange multipliers. It is based on the article by *Selesnick, Lang and Burrus* [58].

FIR filters are a subset of IIR filters. FIR filters are described by a single transfer function polynomial in z^{-1} :

$$h(z) = \sum_{n=0}^N h_n z^{-n}$$

This is called the *direct-form* implementation of the FIR filter. The transfer function of an even-order symmetric FIR filter is:

$$\begin{aligned} h(z) &= \sum_{n=0}^{2M} h_n z^{-n} \\ &= \sum_{n=0}^{M-1} h_n z^{-n} + h_M z^{-M} + \sum_{n=M+1}^{2M} h_n z^{-n} \\ &= z^{-M} \left[h_M + \sum_{n=0}^{M-1} h_n \{ z^{M-n} + z^{-M+n} \} \right] \end{aligned}$$

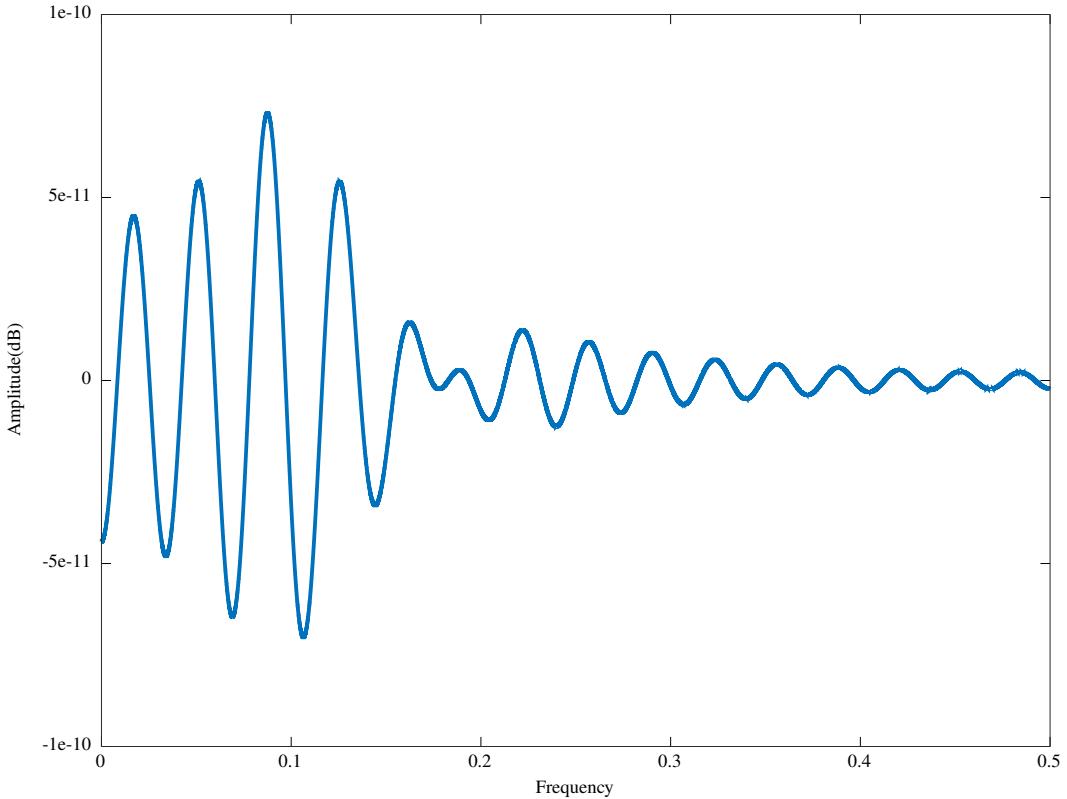

Figure L.3: Combined amplitude responses of the FIR band-pass filter and the minimum-phase complementary filter found with *Mian and Nainer's* cepstral method

where $h_n = h_{N-n}$ and $N = 2M$. The *symmetric-direct-form* implementation requires approximately half the number of multipliers used by the direct-form implementation. A symmetric FIR filter has a linear phase response or, equivalently, a constant group delay response. The direct-form and symmetric-direct-form FIR filter implementations combine all multiplications and additions into a single calculation. These arithmetic operations could be pipelined in a tree structure at the expense of increased delay through the filter. The *transposed-direct-form* FIR filter is an alternative FIR filter implementation that uses *Horner's Rule* to evaluate the filter polynomial:

$$h(z) = (\dots ((h_N z^{-1} + h_{N-1}) z^{-1} + h_{N-2}) z^{-1} + \dots + h_1) z^{-1} + h_0$$

The transposed-direct-form pipelines the arithmetic operations but cannot make use of a symmetry in the filter polynomial.

The zero-phase amplitude response of a symmetric even-order FIR filter is:

$$A(\omega) = h_M + 2 \sum_{n=0}^{M-1} h_n \cos(M-n)\omega$$

Given a desired amplitude response, $A_d(\omega)$, and a weight function, $W(\omega)$, the mean-squared-error of the amplitude response of the symmetric even-order FIR filter is:

$$\mathcal{E} = \frac{1}{\pi} \int_0^\pi W(\omega) [A(\omega) - A_d(\omega)]^2 d\omega$$

The design problem is to minimise the mean-squared-error subject to constraints on the amplitude response:

$$\begin{aligned} A(\omega_p) &\geq L(\omega_p) \\ A(\omega_q) &\leq U(\omega_q) \end{aligned}$$

The method of *Lagrange multipliers* defines a *Lagrangian* function:

$$\mathcal{L}(\omega) = \mathcal{E} - \sum_p \lambda_p [A(\omega_p) - L(\omega_p)] - \sum_q \lambda_q [U(\omega_q) - A(\omega_q)]$$

where λ_p and λ_q are the *Lagrange multipliers* for the amplitude constraints at the corresponding frequencies ω_p and ω_q . The method of Lagrange multipliers minimises \mathcal{E} subject to the constraints by solving the following system of equations for h_n , λ_p and λ_q :

$$\begin{aligned}\frac{\partial \mathcal{E}}{\partial h_n} - \sum_p \lambda_p \frac{\partial A(\omega_p)}{\partial h_n} + \sum_q \lambda_q \frac{\partial A(\omega_q)}{\partial h_n} &= 0 \\ A(\omega_p) &= L(\omega_p) \\ A(\omega_q) &= U(\omega_q)\end{aligned}$$

where:

$$\frac{\partial \mathcal{E}}{\partial h_n} = \frac{2}{\pi} \int_0^\pi W(\omega) [A(\omega) - A_d(\omega)] \frac{\partial A(\omega)}{\partial h_n} d\omega$$

and:

$$\frac{\partial A(\omega)}{\partial h_n} = \begin{cases} 2 \cos(M-n)\omega & n = 0, \dots, M-1 \\ 1 & n = M \end{cases}$$

The minimisation problem can be written in matrix form as:

$$\begin{bmatrix} \mathbf{R} & \mathbf{G}^T \\ \mathbf{G} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \mathbf{h} \\ \boldsymbol{\lambda} \end{bmatrix} = \begin{bmatrix} \mathbf{C} \\ \mathbf{D} \end{bmatrix} \quad (\text{L.8})$$

where \mathbf{R} is a symmetric matrix. The solution is:

$$\begin{aligned}\boldsymbol{\lambda} &= \left(\mathbf{G} \mathbf{R}^{-1} \mathbf{G}^T \right)^{-1} (\mathbf{G} \mathbf{R}^{-1} \mathbf{C} - \mathbf{D}) \\ \mathbf{h} &= \mathbf{R}^{-1} (\mathbf{C} - \mathbf{G}^T \boldsymbol{\lambda})\end{aligned}$$

When the Lagrange multipliers are non-negative, $\lambda_p, \lambda_q \geq 0$, then the *Karush-Kuhn-Tucker* conditions guarantee that the equality-constrained problem also solves the inequality-constrained problem. The exchange algorithm of *Selesnick et al.* solves successive minimisation problems with constraints on the peaks of the response. If any Lagrange multipliers are negative at some iteration then the corresponding constraint frequencies are sequentially dropped so that an inequality-constrained problem is solved.

L.2.1 Examples of the design of constrained least-squared error symmetric FIR filters

This section shows an example of the design of a symmetric FIR band-pass filter by the band-pass exchange algorithm described by *Selesnick et al.* [59, p.498] and summarised in Section 8.1.2. I assume an even order symmetric FIR filter with $\mathbf{h} = [h_0, \dots, h_M]^T$ and piece-wise constant desired amplitude, $A_d(\kappa)$, and weight, $W(\kappa)$, over contiguous regions $\Omega_k \subset [0, \pi]$.

In each region, Ω_k , the mean-squared error is:

$$\mathcal{E} = \frac{1}{\pi} \int_{\Omega_k} W(k) [A(\omega) - A_d(k)]^2 d\omega$$

Similarly, the gradient of the mean-squared error with respect to the coefficients is:

$$\frac{\partial \mathcal{E}}{\partial h_n} = \frac{2}{\pi} \int_{\Omega_k} W(k) [A(\omega) - A_d(k)] \frac{\partial A(\omega)}{\partial h_n} d\omega$$

which can be expressed in the form $2\mathbf{q} + 2\mathbf{Q}\mathbf{h}$. The components of \mathbf{q} and \mathbf{Q} are found with:

$$\int \frac{\partial A(\omega)}{\partial h_n} d\omega = \begin{cases} 2 \frac{\sin(M-n)\omega}{M-n} & n = 0, \dots, M-1 \\ \omega & n = M \end{cases}$$

and:

$$\int A(\omega) \frac{\partial A(\omega)}{\partial h_n} d\omega = \begin{cases} 2 \sum_{m=0}^M h_m \frac{\sin(2M-m-n)\omega}{2M-m-n} + 2h_n\omega + 2 \sum_{m=0, m \neq n}^{M-1} h_m \frac{\sin(n-m)\omega}{n-m} & n = 0, \dots, M-1 \\ h_M\omega + 2 \sum_{m=0}^{M-1} h_m \frac{\sin(M-m)\omega}{M-m} & n = M \end{cases}$$

since, for $n = 0, \dots, M - 1$:

$$\int A(\omega) \cos(M-n)\omega d\omega = \sum_{m=0}^M h_m \int \cos(2M-m-n)\omega d\omega + \sum_{m=0}^{M-1} h_m \int \cos(n-m)\omega d\omega$$

The octave function *directFIRsymmetricEsqPW* implements the piece-wise calculation of \mathcal{E} and its gradients with respect to h_n .

Design of a constrained least-squared error symmetric FIR low-pass filter

The Octave script *directFIRsymmetric_slb_lowpass_test.m* implements the design of a symmetric FIR low-pass filter with constraints on the amplitude response by the method of Lagrange multipliers. The matrix equation shown above in Equation L.8 is solved by left division in the Octave function *directFIRsymmetric_mmsePW* and the exchange algorithm of Selesnick *et al.* is implemented by the Octave function *directFIRsymmetric_slb*. The low-pass filter specification is:

```
tol=1e-05 % Tolerance on coefficient update vector
ctol=1e-05 % Tolerance on constraints
nplot=1000 % Frequency points across the band
M=15 % M+1 distinct coefficients
fap=0.1 % Amplitude pass band edge
dBap=0.02 % Amplitude pass band peak-to-peak ripple
Wap=1 % Amplitude pass band weight
fas=0.2 % Amplitude stop band edge
dBas=52 % Amplitude stop band peak-to-peak ripple
Was=10 % Amplitude stop band weight
```

The bandwidth of the constrained low-pass filter is slightly narrower than that of the initial unconstrained filter. The amplitude responses of the initial and optimised low-pass filters are shown in Figure L.4. The distinct optimised filter coefficients are:

```
hM1 = [ 0.0015415562, 0.0021622752, -0.0004724047, -0.0057312301, ...
-0.0081256352, -0.0016428074, 0.0123722369, 0.0218047186, ...
0.0115474186, -0.0202014306, -0.0510078994, -0.0433674249, ...
0.0270095515, 0.1450930022, 0.2573031209, 0.3034299040 ]';
```

Figure L.5 shows the initial response and the response obtained when one coefficient of the exact solution is rounded and the remaining coefficients are optimised with the pass-band ripple constraint relaxed.

Design of a constrained least-squared error symmetric FIR band-pass filter

Similarly to the previous example, the Octave script *directFIRsymmetric_slb_bandpass_test.m* implements the design of a symmetric FIR band-pass filter with constraints on the amplitude response by the method of Lagrange multipliers. The band-pass filter specification is:

```
tol=1e-05 % Tolerance on coefficient update vector
ctol=1e-05 % Tolerance on constraints
nplot=1000 % Frequency points across the band
M=16 % M+1 distinct coefficients
fapl=0.1 % Amplitude pass band lower edge
fapu=0.2 % Amplitude pass band upper edge
Wap=1 % Amplitude pass band weight
dBap=1 % Amplitude pass band peak-to-peak ripple
fasl=0.05 % Amplitude lower stop band edge
Wasl=20 % Amplitude lower stop band weight
fasu=0.25 % Amplitude upper stop band edge
Wasu=40 % Amplitude upper stop band weight
dBas=36.947 % Amplitude stop band peak-to-peak ripple
```

The amplitude responses of the initial and optimised band-pass filters are shown in Figure L.6. The distinct optimised filter coefficients are:

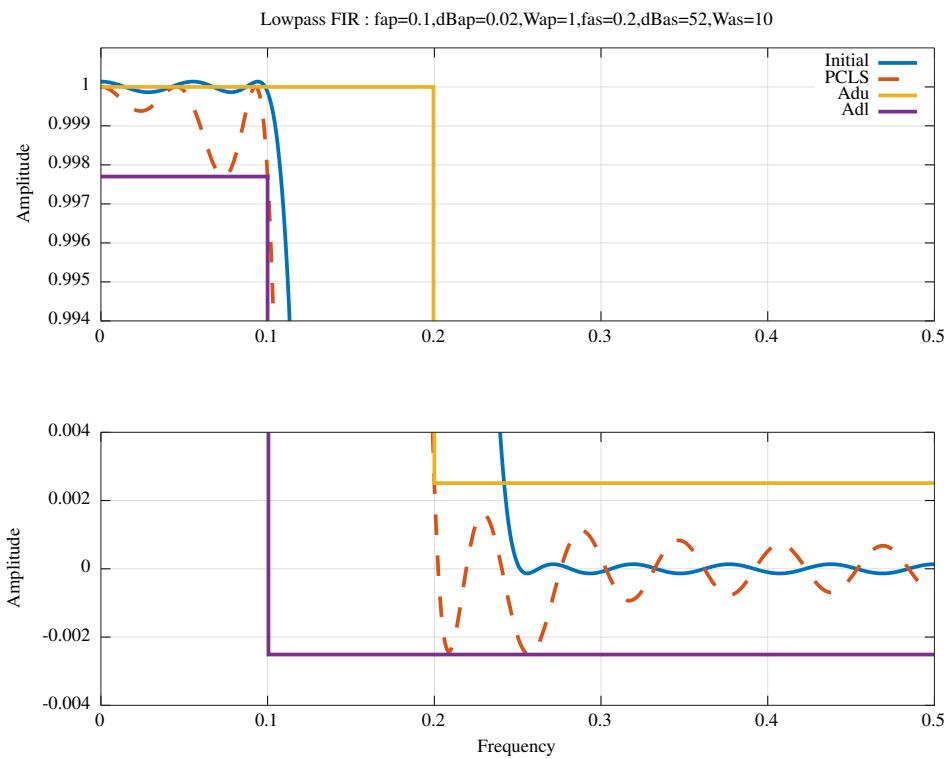

Figure L.4: Amplitude response of the initial FIR low-pass filter, upper and lower response constraint mask and the optimised low-pass FIR filter designed with the method of Lagrange multipliers and the exchange algorithm of *Selesnick et al.* .

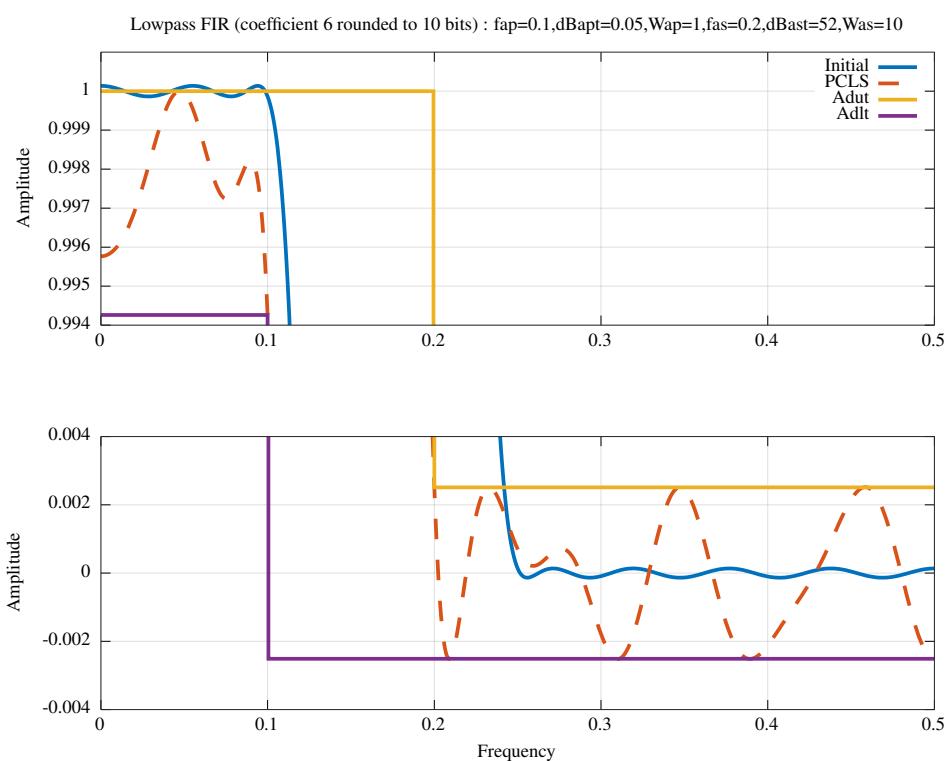

Figure L.5: Amplitude response of the initial FIR low-pass filter, upper and lower response constraint mask and the optimised band pass FIR filter designed with one coefficient rounded and the remaining coefficients optimised by the method of Lagrange multipliers and the exchange algorithm of *Selesnick et al.* .

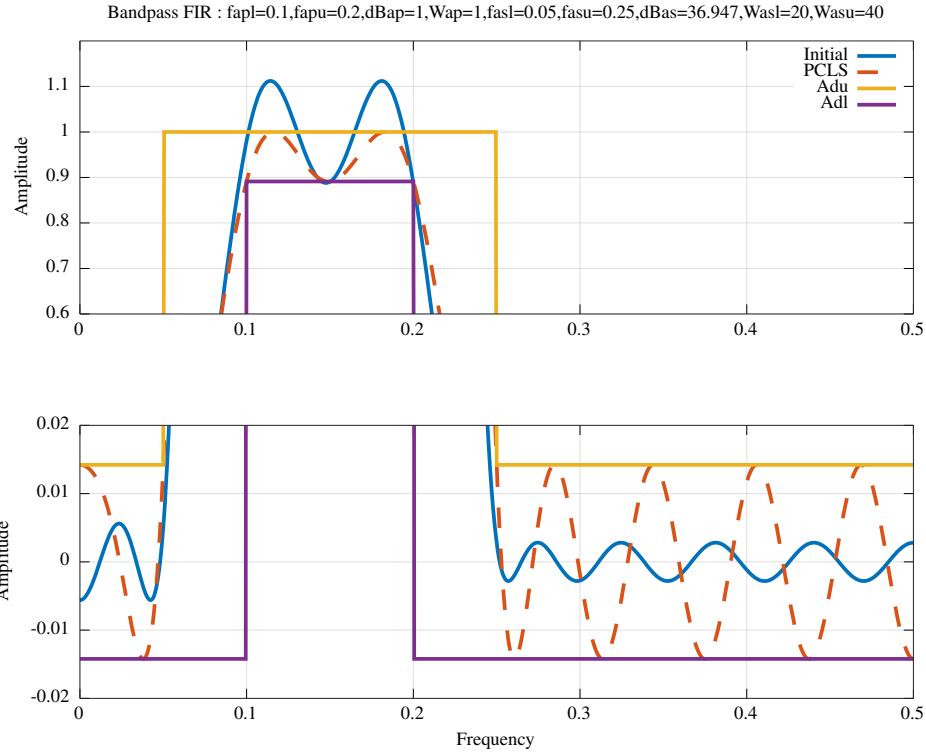

Figure L.6: Amplitude response of the initial FIR band-pass filter, upper and lower response constraint mask and the optimised band-pass FIR filter designed with the method of Lagrange multipliers and the exchange algorithm of *Selesnick et al.*.

```
hM1 = [ -0.0058181010, 0.0017787857, -0.0047084625, -0.0143846688, ...
-0.0077550125, 0.0219788564, 0.0432578789, 0.0247317110, ...
-0.0077853817, -0.0010276677, 0.0304650309, 0.0009925325, ...
-0.1110651112, -0.1806101683, -0.0725659905, 0.1536437055, ...
0.2719559562 ]';
```

Figure L.7 shows the initial response and the response obtained when three coefficients of the exact solution are rounded and the remaining coefficients are optimised with the stop-band ripple constraint relaxed.

L.3 Constrained least-squared error optimisation of direct-form FIR Hilbert digital filters

The frequency response of an ideal Hilbert transform filter is [107, pp.791-792]:

$$H(\omega) = \begin{cases} -i & 0 < \omega < \pi \\ i & -\pi < \omega < 0 \end{cases}$$

The corresponding impulse response is:

$$\begin{aligned} h_n &= \frac{1}{2\pi} \int_{-\pi}^0 e^{i\omega n} d\omega - \frac{1}{2\pi} \int_0^\pi e^{i\omega n} d\omega \\ &= \begin{cases} \frac{2 \sin^2 \frac{\pi n}{2}}{\pi n} & n \neq 0 \\ 0 & n = 0 \end{cases} \end{aligned}$$

Clearly $h_n = -h_{-n}$ and $h_{2n} = 0$. If the causal FIR Hilbert filter is truncated to order $4M$ then there are M distinct coefficients, the group-delay of the filter is $2M$ samples and the z-transform of the filter is:

$$H(z) = z^{-2M} \sum_{m=0}^{M-1} h_{2m+1} [z^{-(2m+1)} - z^{(2m+1)}]$$

Bandpass FIR (coefficients 7,9,11 rounded to 8 bits) : fapl=0.1,fapu=0.2,dBapt=3,fasl=0.05,fasu=0.25,dBast=25

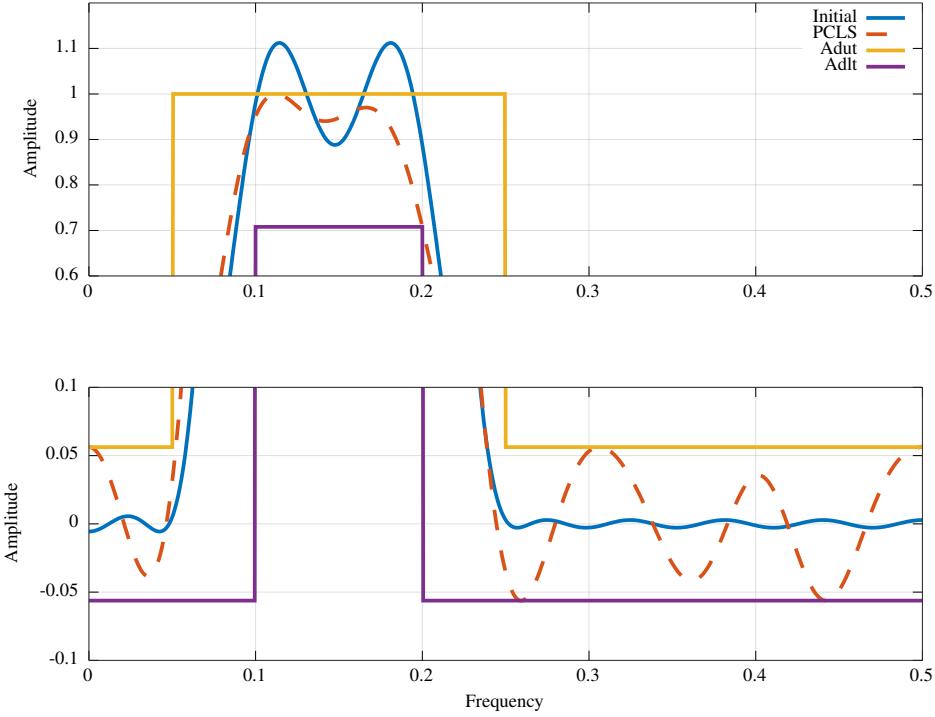

Figure L.7: Amplitude response of the initial FIR band-pass filter, upper and lower response constraint mask and the optimised band-pass FIR filter designed with three coefficients rounded and the remaining coefficients optimised by the method of Lagrange multipliers and the exchange algorithm of Selesnick *et al.*.

The zero-phase amplitude response of the FIR Hilbert filter is:

$$A(\omega) = 2 \sum_{m=0}^{M-1} h_{2m+1} \sin((2m+1)\omega)$$

The design problem is to minimise the mean-squared-error subject to constraints on the amplitude response:

$$\begin{aligned} \mathcal{E} &= \frac{1}{\pi} \int_0^\pi W(\omega) [A(\omega) - 1]^2 d\omega \\ A(\omega_p) &\geq L(\omega_p) \\ A(\omega_q) &\leq U(\omega_q) \end{aligned}$$

In a similar fashion to that shown in Appendix L.2, the method of *Lagrange multipliers* optimises the mean-squared-error by solving the following system of equations for h_{2m+1} , λ_p and λ_q :

$$\begin{aligned} \frac{\partial \mathcal{E}}{\partial h_{2m+1}} - \sum_p \lambda_p \frac{\partial A(\omega_p)}{\partial h_{2m+1}} + \sum_q \lambda_q \frac{\partial A(\omega_q)}{\partial h_{2m+1}} &= 0 \\ A(\omega_p) &= L(\omega_p) \\ A(\omega_q) &= U(\omega_q) \end{aligned}$$

where:

$$\frac{\partial \mathcal{E}}{\partial h_{2m+1}} = \frac{2}{\pi} \int_0^\pi W(\omega) [A(\omega) - 1] \frac{\partial A(\omega)}{\partial h_{2m+1}} d\omega$$

and:

$$\frac{\partial A(\omega)}{\partial h_{2m+1}} = 2 \sin((2m+1)\omega) \quad m = 0, \dots, M-1$$

This system of equations can be expressed in matrix form with components given by:

$$\int \frac{\partial A(\omega)}{\partial h_{2m+1}} d\omega = -2 \frac{\cos((2m+1)\omega)}{(2m+1)} \quad m = 0, \dots, M-1$$

$$\int A(\omega) \frac{\partial A(\omega)}{\partial h_{2m+1}} d\omega = 2h_{2m+1}\omega + 2 \sum_{l=0, l \neq m}^{M-1} h_{2l+1} \frac{\sin(2l-2m)\omega}{2l-2m} - 2 \sum_{l=0}^{M-1} h_{2l+1} \frac{\sin(2l+2m+2)\omega}{2l+2m+2}$$

L.3.1 Design of a constrained least-squared error anti-symmetric FIR Hilbert filter

The Octave script *directFIRhilbert_slb_test.m* implements the design of an FIR Hilbert filter with constraints on the amplitude response by the method of Lagrange multipliers. The matrix equation shown above in Equation L.8 is solved by left division in the Octave function *directFIRhilbert_mmse* and the PCLS exchange algorithm of Selesnick *et al.* is implemented by the Octave function *directFIRhilbert_slb*. The FIR Hilbert filter specification is:

```
tol=0.0001 % Tolerance on coefficient update vector
ctol=0.0001 % Tolerance on constraints
npoints=1000 % Frequency points across the band
M=8 % M distinct coefficients
fapl=0.025 % Amplitude pass band lower edge
fapu=0.475 % Amplitude pass band upper edge
Wap=1 % Amplitude pass band weight
dBap=1 % Amplitude pass band peak-to-peak ripple
Was=0 % Amplitude stop band weight
```

The group delay of the filter is $2M$ samples. The bandwidth of the constrained Hilbert filter is slightly wider than that of the initial unconstrained filter. The PCLS pass-band response is constrained to be less than 1. The amplitude responses of the initial and optimised Hilbert filters are shown in Figure L.8. The FIR Hilbert filter pass-band response is symmetrical about the frequency 0.25, where the sampling rate is normalised to 1. The distinct optimised filter coefficients are:

```
hM2 = [ 0.6215201682, 0.1953915021, 0.1089947924, 0.0711146078, ...
        0.0497051406, 0.0355023200, 0.0253928197, 0.0176413081 ]';
```

The corresponding FIR filter is:

```
h2=[-flipud(kron(hM2,[1;0]));0;kron(hM2,[1;0])](2:end-1)
```

L.3.2 Design of a constrained least-squared error anti-symmetric FIR Hilbert band-pass filter

The Octave script *directFIRhilbert_bandpass_slb_test.m* designs an FIR Hilbert filter with a band-pass response. The corresponding filter specification is:

```
tol=0.0001 % Tolerance on coefficient update vector
ctol=0.0001 % Tolerance on constraints
npoints=1000 % Frequency points across the band
M=8 % M distinct coefficients
fasl=0.1 % Amplitude stop band lower edge
fapl=0.16325 % Amplitude pass band lower edge
fapu=0.33675 % Amplitude pass band upper edge
fasu=0.4 % Amplitude stop band upper edge
Wap=1 % Amplitude pass band weight
dBap=0.315 % Amplitude pass band peak-to-peak ripple
Wat=0.001 % Amplitude transition band weight
Was=10 % Amplitude stop band weight
dBas=35 % Amplitude stop band peak ripple
```

The amplitude responses of the initial and optimised Hilbert filters are shown in Figure L.9. The pass-band responses are shown in Figure L.10. The distinct optimised filter coefficients are:

```
hM2 = [ 0.4239235327, -0.1596092306, -0.0550052923, 0.0629162600, ...
        0.0144604946, -0.0291468051, -0.0031738998, 0.0104589390 ]';
```

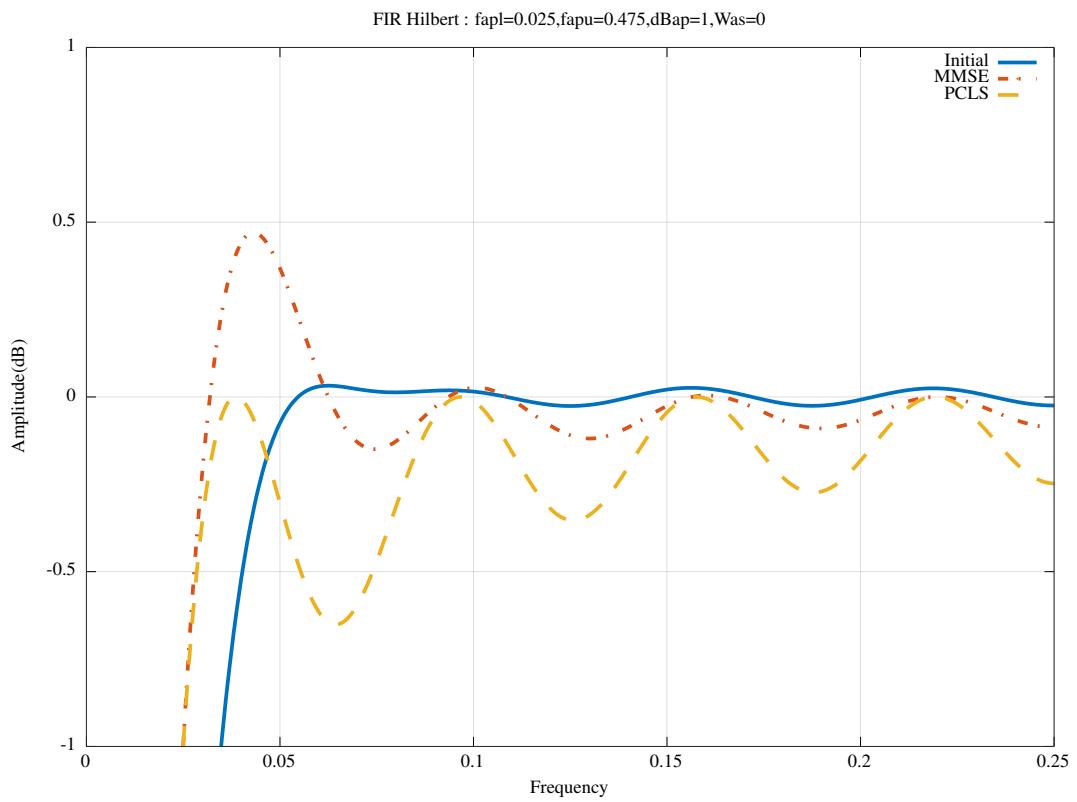

Figure L.8: Amplitude response of the initial FIR Hilbert filter and the optimised FIR Hilbert filter designed with the method of Lagrange multipliers and the exchange algorithm of Selesnick *et al.* .

L.4 Constrained mini-max error optimisation of FIR digital filters

L.4.1 Alternation theorem

A symmetric or linear phase FIR filter with even order $2M$ and a symmetric impulse response with $2M + 1$ coefficients has zero-phase frequency response:

$$\begin{aligned} A(\omega) &= h_M + 2 \sum_{k=0}^{M-1} h_k \cos(M-k)\omega \\ &= \sum_{k=0}^M a_k \cos k\omega \\ &= \sum_{k=0}^M a_k T_k(\cos \omega) \end{aligned}$$

where $T_k(x)$ is the k -th order *Chebyshev polynomial of the first kind*. This section considers methods of minimising the maximum error:

$$\max_{\omega} E(\omega) = W(\omega) |A(\omega) - A_d(\omega)|$$

where $W(\omega)$ is a weighting function and $A_d(\omega)$ is the desired response. This is also called the *Chebyshev distance*. For a given filter order (assumed to be even) the number of frequency constraints is limited by the *approximation theorem*, shown by *Roberts and Mullis* [129, p. 192] as:

Theorem (Chebyshev): Let $d(x)$ be a real-valued function which is continuous on $-1 \leq x \leq 1$.

1. There is a unique polynomial $p(x)$ of degree at most M which minimizes $\|d(x) - p(x)\|_{\infty}$.
2. $p(x)$ is that polynomial if and only if there exist points $-1 \leq x_0 \leq x_1 \leq \dots \leq x_{n+1} \leq 1$ for which

$$d(x_i) - p(x_i) = (-1)^i \varepsilon, \quad i = 0, 1, \dots, n+1$$

where $|\varepsilon| = \|d(x) - p(x)\|_{\infty}$.

Oppenheim and Schafer show a similar theorem [107, Page 489]:

Alternation Theorem: Let F_P denote the closed subset consisting of the disjoint union of closed subsets of the real axis x . Then

$$P(x) = \sum_{k=0}^r a_k x^r$$

is an r -th order polynomial. Also, $D_P(x)$ denotes a given desired function of x that is continuous on F_P ; $W_P(x)$ is a positive function, continuous on F_P , and

$$E_P(x) = W_P(x) [D_P(x) - P(x)]$$

is the weighted error. The maximum error is defined as

$$\|E\| = \max_{x \in F_P} |E_P(x)|$$

A necessary and sufficient condition that $P(x)$ be the unique r th order polynomial that minimises $\|E\|$ is that $E_P(x)$ exhibit at least $(r+2)$ alternations; i.e., there must exist at least $(r+2)$ values x_i in F_P such that $x_1 < x_2 < \dots < x_{r+2}$ and such that $E_P(x_i) = -E_P(x_{i+1}) = \|E\|$ for $i = 1, 2, \dots, (r+1)$.

Oppenheim and Schafer illustrate the conditions under which an extremum of a polynomial function is also considered to be an *alternation* [107, Figure 7.34]. They point out that, for a polynomial of order M , the Alternation Theorem requires that the

optimal approximation have at least $M + 2$ alternations (the *equi-ripple* approximation) and that a low-pass filter may have at most $M + 3$ alternations (the *extra-ripple* case). They include alternations at the pass-band edge (for which the polynomial amplitude is $1 - \delta_p$) and at the stop-band edge (for which the amplitude is $+\delta_s$). Further, the polynomial amplitude will be equi-ripple except possibly at $\omega = 0$ or $\omega = \pi$.

L.4.2 Hofstetter's algorithm for mini-max FIR filter approximation

Hofstetter [31] describes an iterative technique for the design of FIR transfer functions that have the specified pass-band and stop-band ripple. The technique:

begins by making an initial estimate of the frequencies at which these extrema will occur and the uses Lagrange interpolation to obtain a polynomial that goes through the maximum allowable ripple values at these frequencies. ... The next stage of the algorithm is to locate the frequencies at which the extrema of the first Lagrange interpolation polynomial occur. These frequencies are taken to be a second, hopefully improved, guess as to the frequencies at which the extrema of the filter response will achieve the desired ripple values. ... The algorithm now "closes the loop" by using these new frequencies to construct a Lagrange interpolation polynomial that achieves the desired ripple values at these frequencies. The extrema of this new polynomial are then located and used to start the next cycle of the algorithm. The algorithm is reminiscent of, but different from, the Remes exchange algorithm used in the theory of Tchebycheff approximation.

The pass-band constraint frequencies are $\omega_1, \dots, \omega_{N_p}$ and the stop-band constraint frequencies are $\omega_{N_p+1}, \dots, \omega_{N_p+N_s}$, where $M + 1 = N_p + N_s$, $\omega_1 = 0$ and $\omega_{N_p+N_s} = \pi$. At each iteration, the algorithm solves the system of equations:

$$A(\omega_l) = \begin{cases} 1 + (-1)^{l+c} \delta_p & \text{for } 1 \leq l \leq N_p \\ (-1)^{l+c} \delta_s & \text{for } N_p + 1 \leq l \leq N_p + N_s \end{cases}$$

where c is chosen to be 0 or 1. These equations can be solved efficiently by *barycentric Lagrange interpolation*^b [31, Page 5][157, Page 192] [64].

The Octave script *hofstetterFIRsymmetric_lowpass_test.m* uses an implementation of Hofstetter's algorithm in the Octave function *hofstetterFIRsymmetric.m* to design a low-pass filter. The filter specification is:

```
M=41 % Filter order is 2*M
fap=0.1 % Amplitude pass band edge
nMp+1=10 % Amplitude pass band alternations
deltap=0.0001 % Amplitude pass band peak-to-peak ripple
fas=0.2 % Amplitude stop band edge
nMs+1=32 % Amplitude stop band alternations
deltas=1e-06 % Amplitude stop band peak-to-peak ripple
nplot=2000 % Number of frequencies
tol=1e-05 % Tolerance on convergence
```

Figure L.11 shows the pass-band and stop-band amplitude responses of the filter. Figure L.12 shows the zeros of the filter.

The Octave script *hofstetterFIRsymmetric_bandpass_test.m* uses an implementation of Hofstetter's algorithm in the Octave function *hofstetterFIRsymmetric.m* to design a band-pass filter. The filter specification is:

```
M=30 % Filter order is 2*M (M+1 distinct coefficients)
fasl=0.15 % Amplitude stop band lower edge
fapl=0.2 % Amplitude pass band lower edge
fapu=0.25 % Amplitude pass band upper edge
fasu=0.3 % Amplitude stop band upper edge
deltap=0.001 % Amplitude pass band peak-to-peak ripple
deltas=0.001 % Amplitude stop band peak-to-peak ripple
nplot=2000 % Number of frequencies
tol=1e-05 % Tolerance on convergence
```

Figure L.13 shows the pass-band and stop-band amplitude responses of the filter. Figure L.14 shows the zeros of the filter.

Selesnick-Burrus modification to Hofstetter's algorithm for low-pass filters

Selesnick and Burrus [57] point out that whilst Hofstetter's algorithm "produces equi-ripple filters with the specified δ_p and δ_s , it is not widely used because it allows limited control over the location of the band edges and only produces extra-ripple filters". They add a non-extremal frequency constraint in the transition band at ω_t .

Suppose $\omega_1, \dots, \omega_{M+1}$ is the ordered reference set of frequencies in $[0, \pi]$ including ω_t . Let $\omega_1, \dots, \omega_{q-1}$ be the frequencies in the pass-band, less than ω_t , and $\omega_{q+1}, \dots, \omega_{M+1}$ be the frequencies in the stop-band, greater than ω_t . The system of equations to be solved at each iteration is:

$$\begin{aligned} A(\omega_k) &= 1 + (-1)^{k+c} \delta_p \quad \text{for } 1 \leq k \leq q-1 \\ A(\omega_t) &= A_t \\ A(\omega_k) &= (-1)^{k+c+1} \delta_s \quad \text{for } q+1 \leq k \leq M+1 \end{aligned}$$

where c is chosen to equal 0 or 1, whichever yields $A(\omega_{q-1}) = 1 + \delta_p$.

The exchange algorithm is described as follows:

Let S be the set obtained by appending ω_t to the set of extrema of $A(\omega)$ in $[0, \pi]$: S will have either $M+1$ or $M+2$ frequencies and will include both 0 and π . If S has $M+1$ frequencies, then take the new reference set to be S . If S has $M+2$ frequencies, then remove either 0 or π from S according to the following rules:

1. If $A(\omega)$ has no extrema in the open interval $(0, \omega_t)$, then remove 0 from S .
2. If $A(\omega)$ has no extrema in the open interval (ω_t, π) then remove π from S .
3. Otherwise, let ω_a be the extrema of $A(\omega)$ in $(0, \omega_t)$ closest to 0, and let ω_b be the extrema of $A(\omega)$ in (ω_t, π) closest to π . If $|A(0) - A(\omega_a)| \delta_s < |A(\pi) - A(\omega_b)| \delta_s$ then remove 0 from S , otherwise remove π from S .

The Octave script `selesnickFIRsymmetric_lowpass_test.m` designs a low-pass filter with the implementation of Hofstetter's algorithm with the modifications of Selesnick and Burrus in the Octave function `selesnickFIRsymmetric_lowpass.m`. The filter specification is:

```
M=85 % Filter order is 2*M
deltap=1e-06 % Amplitude pass band peak-to-peak ripple
deltas=1e-08 % Amplitude stop band peak-to-peak ripple
ft=0.15 % Amplitude transition band frequency
at=0.999999 % Amplitude at transition band frequency
nplot=4000 % Number of frequencies
tol=1e-08 % Tolerance on convergence
```

Figure L.15 shows the pass-band and stop-band amplitude responses of the filter. Figure L.16 shows the zeros of the filter.

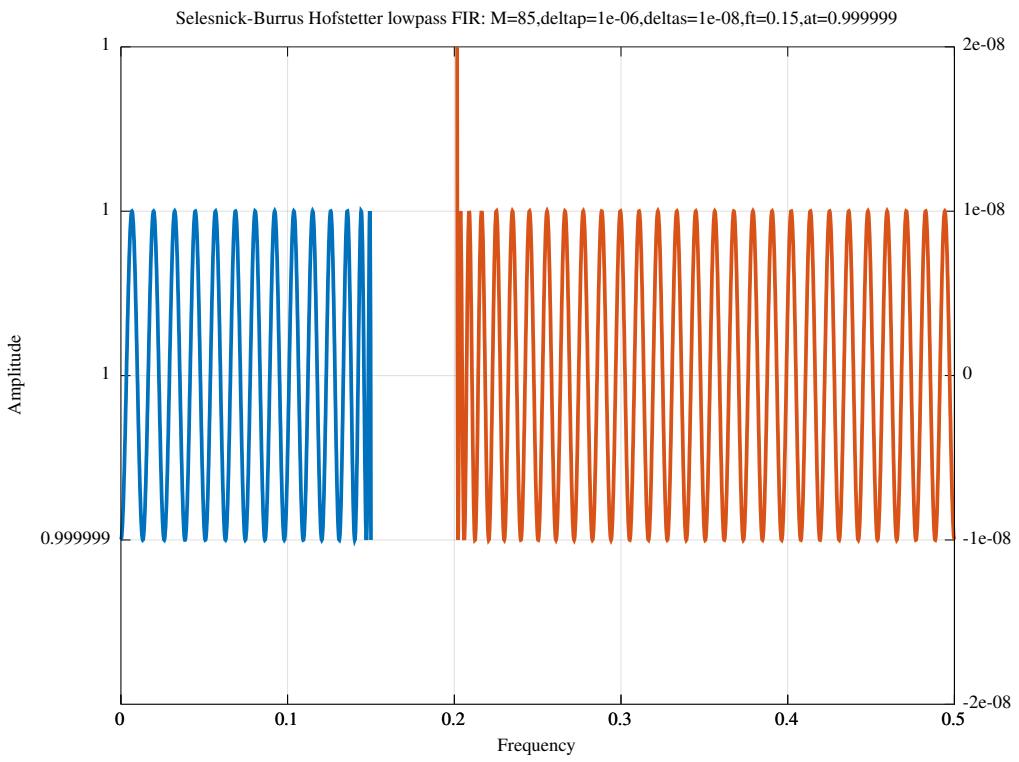

Figure L.15: Response of a mini-max FIR low-pass filter designed with *Hofstetter*'s algorithm and the modifications of *Selesnick* and *Burrus*

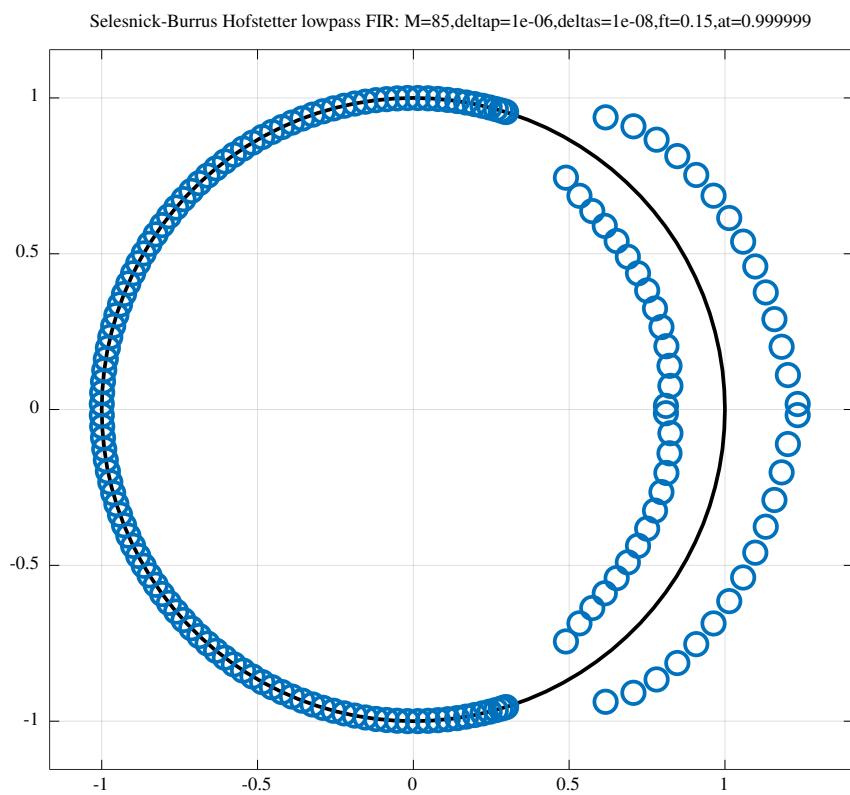

Figure L.16: Zeros of a mini-max FIR low-pass filter designed with *Hofstetter*'s algorithm and the modifications of *Selesnick* and *Burrus*

Selesnick-Burrus modification to Hofstetter's algorithm for band-pass filters

Selesnick and Burrus [57, Section II.C] also describe an exchange algorithm for band-pass filters with lower stop-band, pass-band and upper stop-band errors δ_{sl} , δ_p and δ_{su} and lower and upper transition-band frequencies ω_{tl} and ω_{tu} . An additional constraint makes the slope of $A(\omega)$ is equal in magnitude and opposite in sign at the transition frequencies. *Selesnick and Burrus* state that: “because the reference set must contain $M - 2$ extremal frequencies, it will therefore be necessary to exclude 0, 1, 2 or 3 local minima and maxima when updating the reference set.” Suppose $\omega_1, \dots, \omega_L$ are the local extrema of $A(\omega)$ listed in order. The procedure for excluding maxima and minima is:

1. To exclude 1 local extremum ($L = M - 1$), use the same update rule used for the low-pass case.
2. To exclude 2 local extrema ($L = M$), find the index k that minimises

$$[E(\omega_k) - E(\omega_{k+1})](-1)^{k+c}$$

where $c = 1$ if ω_1 is a local maximum and $c = 0$ if ω_1 is a local minimum. $E(\omega)$ denotes the error function. ... If $1 < k < M - 2$, then exclude ω_k and ω_{k+1} from the reference set. If $k = 1$ or $K = L$, then exclude ω_k and use the procedure above for excluding 1 local extremum.

3. To exclude 3 local extrema ($L = M + 1$), use the procedure for excluding 1 extremum, followed by the procedure for excluding 2 extrema.

The Octave script *selesnickFIRsymmetric_bandpass_test.m* designs a band-pass filter with the implementation of *Hofstetter*'s algorithm with the modifications of *Selesnick and Burrus* in the Octave function *selesnickFIRsymmetric_bandpass.m*. Unlike the MATLAB implementation made available by *Selesnick, firebp.m* [146], this function uses Lagrange interpolation to find the response in the $x = \cos \omega$ domain rather than using left division to find the coefficients directly and does not attempt to implement the constraint on the slope of the response at the transition frequencies. The filter specification is:

```
M=50 % Filter order is 2*M
deltasl=0.002 % Amplitude lower stop-band peak ripple
deltap=0.002 % Amplitude pass-band peak ripple
deltasu=0.001 % Amplitude upper stop-band peak ripple
ftl=0.1 % Amplitude lower transition band frequency
ftu=0.2 % Amplitude upper transition band frequency
at=0.5 % Amplitude at transition band frequencies
nplot=4000 % Number of frequencies
tol=1e-05 % Tolerance on convergence
```

Figure L.17 shows the pass-band and stop-band amplitude responses of the filter.

For comparison, the following Octave code:

```
b=remez(2*M, [0 0.08 0.11 0.19 0.22 0.5]*2, [0 0 1 1 0 0], [2 1 4], "bandpass");
```

designs a filter with the response shown in Figure L.18.

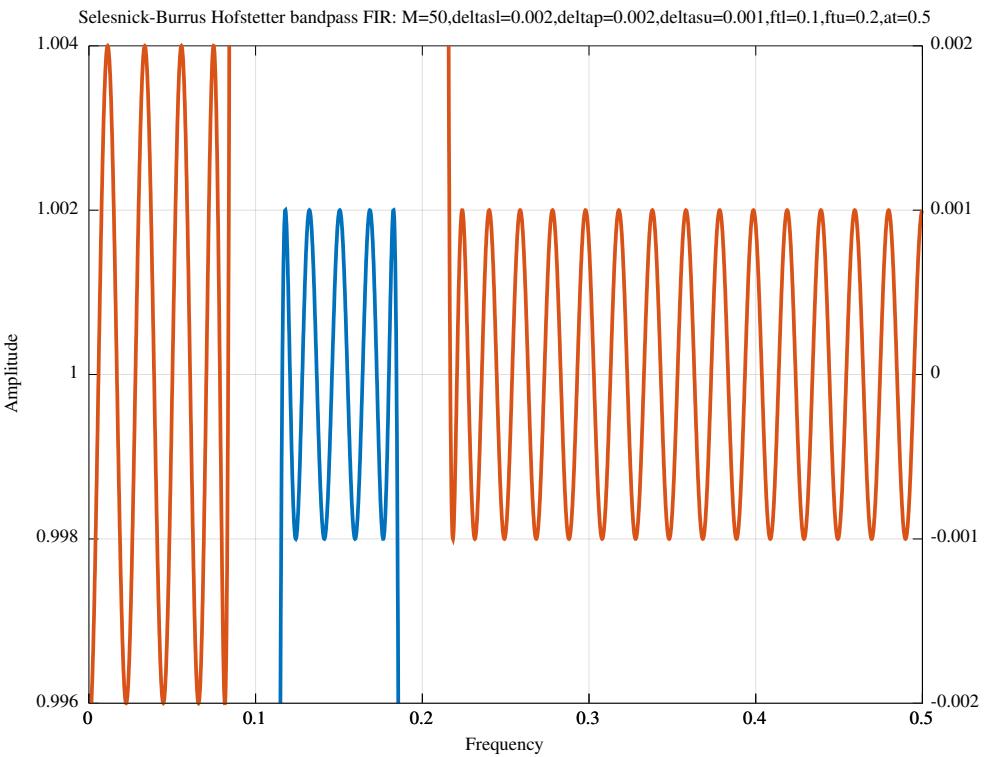

Figure L.17: Response of a mini-max FIR band-pass filter designed with *Hofstetter's* algorithm and the modifications of *Selesnick and Burrus*

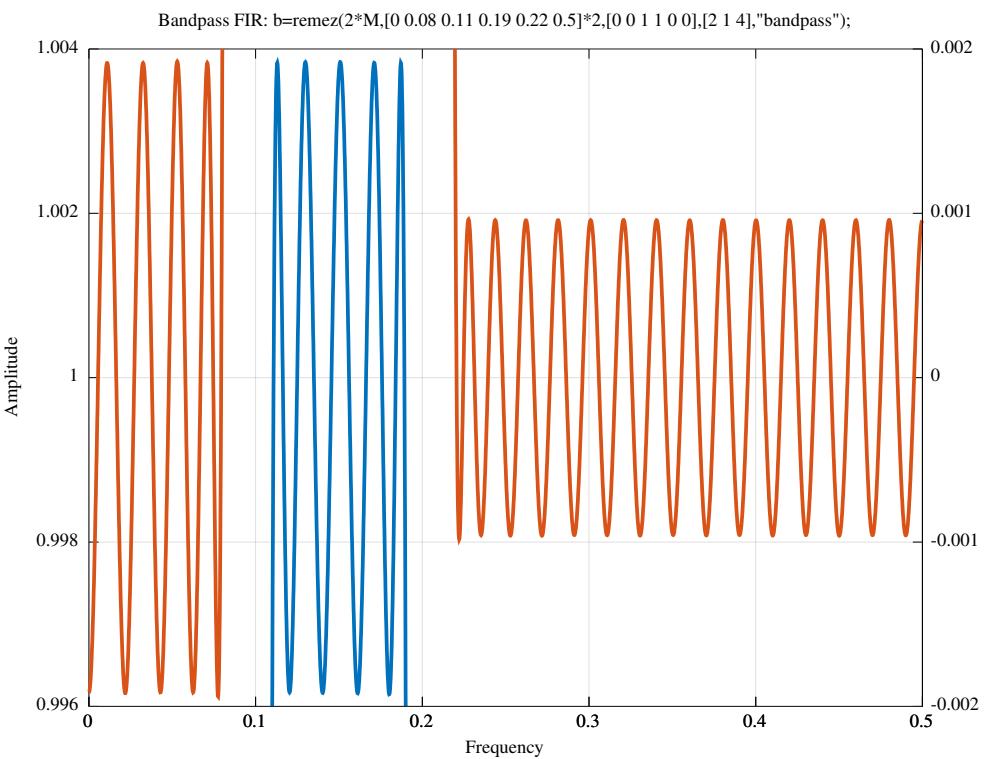

Figure L.18: Response of a mini-max FIR band-pass filter designed with the Octave *remez* function

L.4.3 Parks-McClellan algorithm for mini-max FIR filter approximation

Parks and McClellan [157, 60][107, Section 7.4.3] add extra non-extremal amplitude constraints at the band edges. Their algorithm allows the designer to specify ω_p , ω_s and the ratio δ_p/δ_s but does not allow direct specification of δ_p and δ_s . Parks and McClellan [157] and Oppenheim and Schafer [107, Section 7.4.3] describe the algorithm shown in Algorithm L.2^c.

The Octave *signal* package includes *remez.cc*, an *oct-file* implementation of the *Parks-McClellan* algorithm. Alternatively, the Octave script *mcclellanFIRsymmetric_lowpass_test.m* calls the Octave function *mcclellanFIRsymmetric* to design the *Parks and McClellan* low-pass filter example [157, Table I]. The filter specification is:

```
M=14 % Filter order is 2*M
fap=0.17265 % Amplitude pass band edge
fas=0.26265 % Amplitude stop band edge
K=10 % Stop band weight
nplot=10000 % Number of frequency grid points in [0,0.5]
nplot=10000 % Number of frequency points
maxiter=100 % Maximum iterations
tol=1e-12 % Tolerance on convergence
```

The stop-band ripple found is $\rho = -0.00098839$ and the distinct filter coefficients are:

```
hM = [ -0.0033554474, -0.0060206464, -0.0008106870, 0.0097507927, ...
        0.0083169067, -0.0113360291, -0.0218303021, 0.0048220280, ...
        0.0398898607, 0.0177625604, -0.0583642414, -0.0735976811, ...
        0.0724112343, 0.3065830768, 0.4224251607 ]';
```

Figure L.19 shows the pass-band and stop-band amplitude responses of the filter. Figure L.20 shows the zeros of the filter.

The Octave script *mcclellanFIRsymmetric_bandpass_test.m* designs the band-pass filter with the specification:

```
M=40 % Filter order is 2*M
fasl=0.15 % Amplitude stop band lower edge
fapl=0.2 % Amplitude pass band lower edge
fapu=0.25 % Amplitude pass band upper edge
fasu=0.3 % Amplitude stop band upper edge
K=20 % Stop band weight
nplot=2000 % Number of frequency grid points in [0,0.5]
maxiter=100 % Maximum iterations
tol=1e-12 % Tolerance on convergence
```

In this case, the Octave function *mcclellanFIRsymmetric* does a preliminary search for error alternation failures when finding the error extremal frequencies. In my experience, failure of this error extremal amplitude alternation search indicates that the filter specification is unrealistic. The stop-band ripple found is $\rho = -0.00009082$. Figure L.21 shows the pass-band and stop-band amplitude responses of the filter. Figure L.22 shows the zeros of the filter.

^cNone of the references justify the calculation of ρ (eg: [107, Equation 7.101]). The following is my unsatisfactory attempt. Suppose that the alternations of $A(x_k)$ mean that $\sum_{k=1}^{M+2} |A(x_k) - A_d(x_k)|$ may be approximated by $\sum_{k=1}^{M+2} (-1)^{k+1} A(x_k) / 2$ and that, since $|x - x_k| \leq 2$, $(x - x_k)$ is replaced with 2. For the minimum possible approximation error:

$$\sum_{k=1}^{M+2} b_k \left[A_d(x_k) - \frac{(-1)^{k+1} \rho}{W(x_k)} \right] = 0$$

The result follows. In his MATLAB scripts [146], Selesnick avoids this difficulty by directly calculating ρ and the coefficients of $A(x)$ by left-division.

Algorithm L.2 Parks-McClellan FIR filter design [107, Section 7.4.3] [157, 60]

1. The optimum filter satisfies the equations:

$$W(\omega_k) [A_d(\omega_k) - A(\omega_k)] = (-1)^{k+1} \rho, \quad k = 1, 2, \dots, (M+2)$$

where

$$A(e^{j\omega}) = \sum_{k=0}^M a_k (\cos \omega)^k$$

For a lowpass filter, the approximation polynomial has values $A(\omega_k) = 1 \pm K\rho$ if $W(\omega) = \frac{1}{K}$ in $0 \leq \omega_k \leq \omega_p$ and $A(\omega_k) = \pm \rho$ if $W(\omega) = 1$ in $\omega_s \leq \omega_k \leq \pi$ [107, Equation 7.85].

2. Begin by guessing a set of alternation frequencies, $\omega_1, \omega_2, \dots, \omega_{M+2}$. This set includes the pass-band and stop-band frequencies, ω_p and ω_s . If $\omega_k = \omega_p$ then $\omega_{k+1} = \omega_s$.
3. The required values at the extremal frequencies are given by [107, Equation 7.101]:

$$\rho = \frac{\sum_{k=1}^{M+2} b_k A_d(x_k)}{\sum_{k=1}^{M+2} \frac{b_k (-1)^{k+1}}{W(x_k)}}$$

where [107, Equation 7.102]

$$b_k = \prod_{l=1, l \neq k}^{M+2} \frac{1}{(x_k - x_l)}$$

and $x_k = \cos \omega_k$.

4. $A(\omega)$ is an M -th order polynomial in $x = \cos \omega$ so we can interpolate through $M+1$ of the $M+2$ known values of $A(x)$. The Lagrange interpolation formula gives [107, Equation 7.103a]

$$A(x) = \frac{\sum_{k=1}^{M+1} \frac{d_k}{(x-x_k)} C_k}{\sum_{k=1}^{M+1} \frac{d_k}{(x-x_k)}}$$

where [107, Equation 7.103b]

$$C_k = A_d(x) - \frac{(-1)^{k+1} \rho}{W(x_k)}$$

and [107, Equation 7.103c]

$$d_k = \prod_{l=1, l \neq k}^{M+1} \frac{1}{(x_k - x_l)}$$

5. Now $A(x)$ and the error, $E(x) = A(x) - A_d(x)$, can be calculated at a dense grid of frequencies. If $|E(x)| \leq \rho$ for all x in the pass-band and stop-band, then the optimal filter is found. Otherwise, this procedure is repeated with a new set of extremal frequencies chosen at the $M+2$ greatest values of $|E(x)|$.
6. The impulse response can be approximated with equally spaced samples of the frequency response (calculated by Lagrange interpolation) and the *discrete Fourier transform pair* [129, Section 4.5]:

$$F(l) = \sum_{k=0}^{N-1} f(k) W_N^{-kl}$$

$$f(k) = \frac{1}{N} \sum_{l=0}^{N-1} F(l) W_N^{kl}$$

where $N = 2M + 1$ and $W_N = e^{\frac{2\pi i}{N}}$.

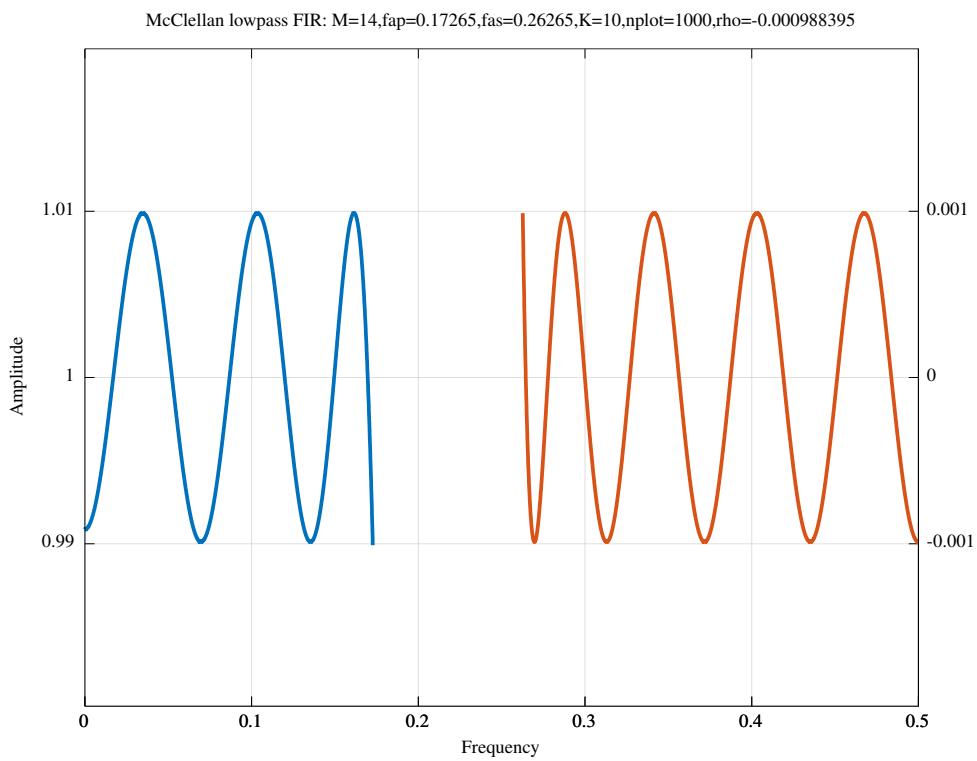

Figure L.19: Response of a mini-max FIR low-pass filter designed with the *Parks and McClellan* algorithm [157, Table I]

Figure L.24: Zeros of a mini-max FIR multi-band filter designed with the *Parks and McClellan* algorithm [157, Table I]

Selesnick-Burrus modification to the Parks-McClellan algorithm

Selesnick and Burrus describe modifications to the *Parks-McClellan* algorithm [57, Section II.A] that allow either the pass-band or stop-band ripple, δ_p or δ_s , to be fixed and the other minimised. The user specifies M , ω_p , ω_s , K_p , K_s , η_p and η_s satisfying:

$$\begin{aligned}\delta_p &= K_p \delta + \eta_p \\ \delta_s &= K_s \delta + \eta_s\end{aligned}$$

The parameters K_p , $K_s \eta_p$ and η_s must be non-negative and satisfy the inequalities $K_p + \eta_p > 0$ and $K_s + \eta_s > 0$. When $\eta_p = \eta_s = 0$ the linear relationship reduces to the usual *Parks-McClellan* algorithm. Alternatively, if $K_s = \eta_p = 0$, then the stop-band ripple, $\delta_s = \eta_s$ and the pass-band ripple, δ_p , is minimised.

The linear system of equations to be solved at each iteration is, in addition to the affine equations for δ_p and δ_s :

$$A(\omega_k) = \begin{cases} 1 + (-1)^{k+c} \delta_p & \text{for } 1 \leq k \leq q \\ (-1)^{k+c} \delta_s & \text{for } q+1 \leq k \leq M+2 \end{cases}$$

where $\omega_p = \omega_q$ and $\omega_s = \omega_{q+1}$ and c is chosen to be 0 or 1 so that $A(\omega_q) = 1 - \delta_p$.

If δ_p or δ_s are found to be negative then the interpolation step should be repeated. If $\delta_p < 0$:

$$\begin{aligned}A(\omega_k) &= \begin{cases} 1 + (-1)^{k+c} \delta_p & \text{for } 1 \leq k \leq q \\ 0 & \text{for } q+1 \leq k \leq M+2 \end{cases} \\ \delta_s &= 0\end{aligned}$$

If $\delta_s < 0$:

$$\begin{aligned}A(\omega_k) &= \begin{cases} 1 & \text{for } 1 \leq k \leq q \\ (-1)^{k+c} \delta_s & \text{for } q+1 \leq k \leq M+2 \end{cases} \\ \delta_p &= 0\end{aligned}$$

The exchange algorithm is described as follows:

The procedure to update the reference set from one iteration to the next is the multiple exchange of the PM algorithm: Let S be the set obtained by appending ω_p and ω_s to the set of extrema of $A(\omega)$ in $[0, \pi]$. S will have either $M+2$ or $M+3$ frequencies and will include both 0 and π . If S has $M+2$ frequencies, then take the new reference set to be S . If S has $M+3$ frequencies, then remove either 0 or π from S according to the following rule: If $\omega = 0$ is a local maximum of $A(\omega)$ then let $\alpha = 1$, otherwise set $\alpha = -1$. If $\omega = \pi$ is a local maximum of $A(\omega)$ then let $\beta = 1$, otherwise set $\beta = -1$. If

$$[A(0) - 1]\alpha - \delta_p < A(\pi)\beta - \delta_s$$

then remove 0 from S , otherwise remove π from S , and take the new reference set to be the resulting set S . The expressions on each side of the inequality indicate the amount by which the error exceeds its intended value. α and β must be chosen appropriately because both the magnitude and the sign of this value is important: negative values appear in the design of filters possessing a scaled extra-ripple. The rule states that the frequency to be retained in S is the one at which the error exceeds its intended value the most.

A MATLAB example, *faffine.m*, of low-pass filter design with this algorithm is available [146]. That function solves for the coefficients, δ , δ_p and δ_s by left division [57, Equation 4]. The Octave script *affine_mcclellanFIRsymmetric_lowpass_test.m* calls a slightly modified version of *faffine.m* to design a low-pass filter with the following specification:

```
M=200 % Filter order is 2*M
fap=0.1 % Amplitude pass band edge
fas=0.11 % Amplitude stop band edge
Kp=1 % Pass band weight
Ks=0 % Stop band weight
etap=0 % Pass band eta
etas=0.0001 % Stop band eta
```

The resulting filter has $\delta_p = 0.00085270$. Figure L.25 shows the pass-band and stop-band amplitude responses of the filter.

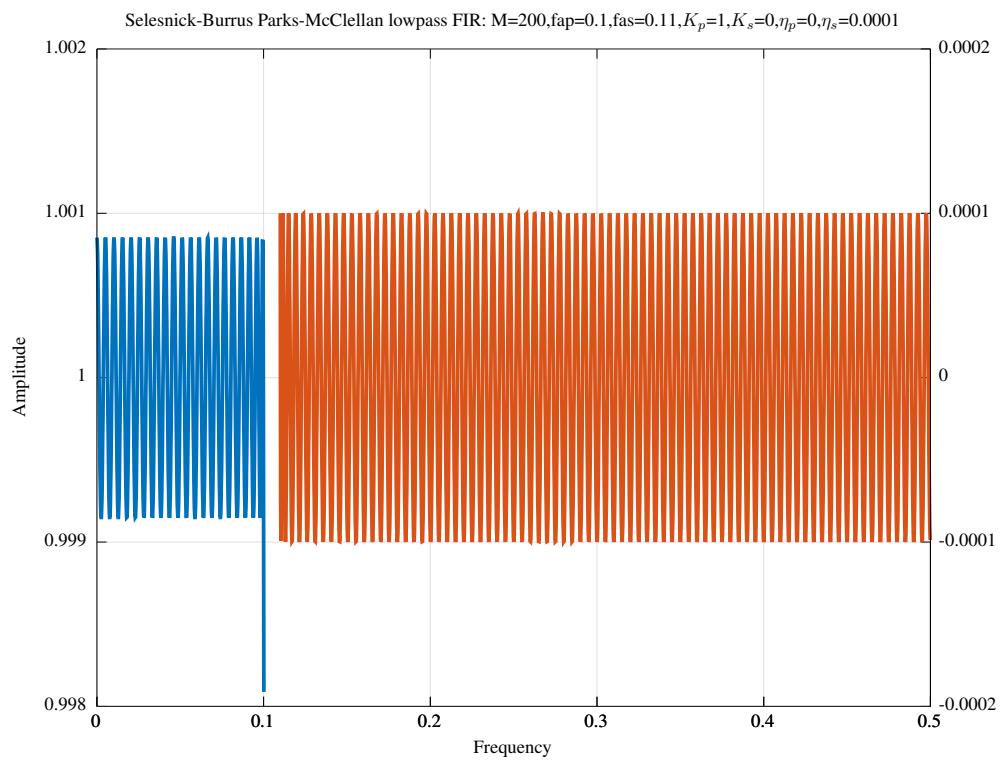

Figure L.25: Response of a mini-max FIR low-pass filter designed with the *Parks and McClellan* algorithm modified by *Selesnick and Burrus* [57, Section II.A].

L.5 Design of FIR filters with flat pass-bands and equi-ripple stop-bands

Flat pass-band filters are preferred when a signal is repeated or re-transmitted many times. *Vaidyanathan* [111] and *Selesnick* and *Burrus* [56] describe the design of FIR filters with flat pass-bands and equi-ripple stop-bands. *Selesnick* and *Burrus* interpret the flat pass-band FIR filter structure proposed by *Vaidyanathan* [111, Figure 4] as [56, Figure 2]:

$$H(z) = z^{-\frac{N-1}{2}} + H_L(z) H_M(z)$$

where:

$$H_L(z) = \left(\frac{1 - z^{-1}}{2} \right)^L$$

N is odd and $H_M(z)$ is a high-pass filter with a symmetric impulse response of length $N - L$. $H_M(e^{j\omega})$ can be written:

$$H_M(e^{j\omega}) = e^{-j\omega(\frac{N-L-1}{2})} A_M(\omega)$$

where $A_M(\omega)$ is a real valued function. When L is chosen to be even:

$$\left(\frac{1 - e^{-j\omega}}{2} \right)^L = (-1)^{\frac{L}{2}} (e^{-\frac{j\omega}{2}})^L \left(\sin \frac{\omega}{2} \right)^L$$

Therefore the frequency response is:

$$H(e^{j\omega}) = e^{-j\omega(\frac{N-1}{2})} A(\omega)$$

where the amplitude response is:

$$A(\omega) = 1 + (-1)^{\frac{L}{2}} \left(\sin \frac{\omega}{2} \right)^L A_M(\omega)$$

Let $M = (N - L - 1)/2$ then:

$$A_M(\omega) = h_M(M) + 2 \sum_{k=0}^{M-1} h_M(k) \cos [\omega(M - k)]$$

where h_M are the coefficients of H_M .

L.5.1 Design of FIR low-pass filters with flat pass-bands and equi-ripple stop-bands

Selesnick and *Burrus* describe exchange algorithms for the cases in which the maximally-flat pass-band, low-pass, FIR filter design:

1. specifies N, L, ω_s and minimises δ_s
2. specifies N, L, δ_s and minimises ω_s

Maximally-flat pass-band and fixed ω_s

In the first case, $A_M(\omega)$ is found by minimising [56, Section II.A]:

$$\|[A_M(\omega) - D(\omega)] W(\omega)\|_\infty$$

where:

$$D(\omega) = -\frac{(-1)^{\frac{L}{2}}}{\left(\sin \frac{\omega}{2} \right)^L}$$

$$W(\omega) = \begin{cases} 0 & \text{for } \omega < \omega_s \\ (-1)^{\frac{L}{2}} \left(\sin \frac{\omega}{2} \right)^L & \text{for } \omega \geq \omega_s \end{cases}$$

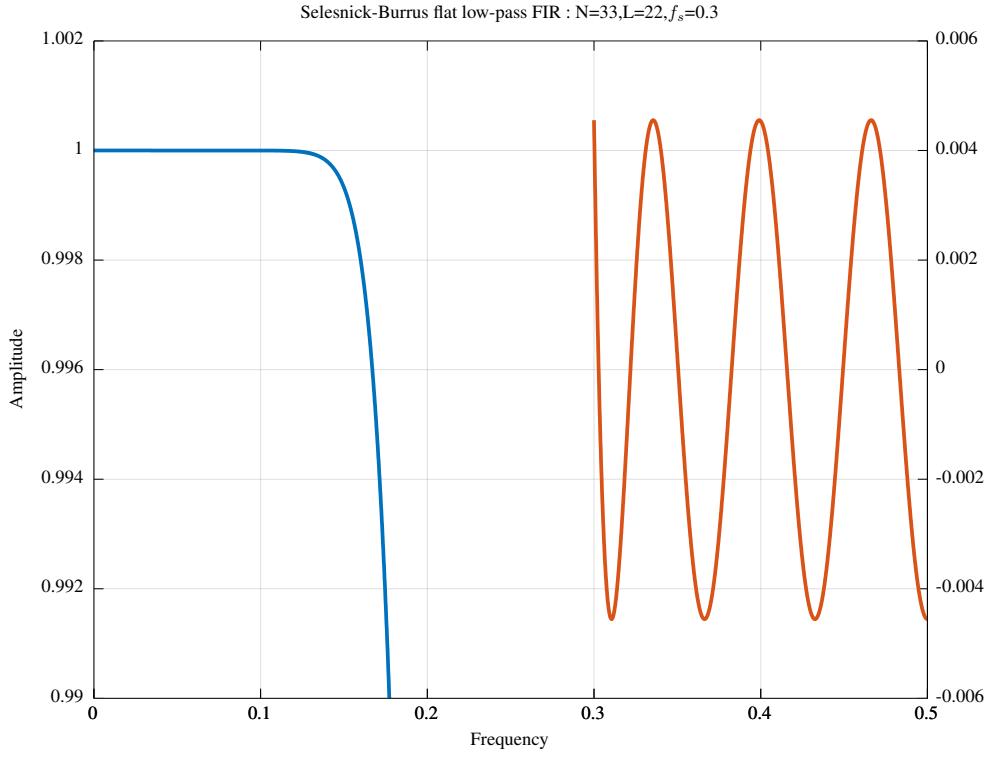

Figure L.26: Response of a mini-max FIR maximally-flat pass-band low-pass filter with fixed ω_s designed with the *Parks and McClellan* algorithm [56, Section II.A].

On each iteration, a reference set of stopband frequencies is updated and the filter H_M is found such that $A(\omega)$ alternately interpolates δ_s and $-\delta_s$, over the reference set frequencies. The size of the reference set is $q = (N - L + 3)/2$.

The Octave script *mcclellanFIRsymmetric_flat_lowpass_test.m* calls the Octave function *mcclellanFIRsymmetric* to design a maximally-flat FIR low-pass filter having fixed ω_s with the *Parks-McClellan* algorithm (Algorithm L.2). The specification of the filter is:

```
N=33 % Filter length
L=22 % Filter flat-ness
fs=0.3 % Amplitude stop band frequency
nplot=4000 % Number of frequency points
maxiter=100 % Maximum iterations
tol=1e-05 % Tolerance on convergence
```

Figure L.26 shows the pass-band and stop-band amplitude responses of the fixed ω_s filter.

Maximally-flat pass-band and fixed δ_s

In the second case [56, Section II.B]:

Like the Remez algorithm, this approach employs a set of stopband reference frequencies. On each iteration: 1) an interpolation problem is solved and 2) the reference set is updated. The reference set here, however, does not contain the stopband edge (indeed, it is not specified). Therefore the reference set contains $(N - L + 1)/2$ stopband frequencies. ... At each iteration, the local extremal frequencies of $A(\omega)$ in $(0, \pi]$ are found and are taken to be the reference set frequencies for the next iteration.

The Octave script *mcclellanFIRsymmetric_flat_lowpass_test.m* calls the Octave function *selesnickFIRsymmetric_flat_lowpass* to design a maximally-flat FIR low-pass filter having fixed δ_s . The specification of the filter is:

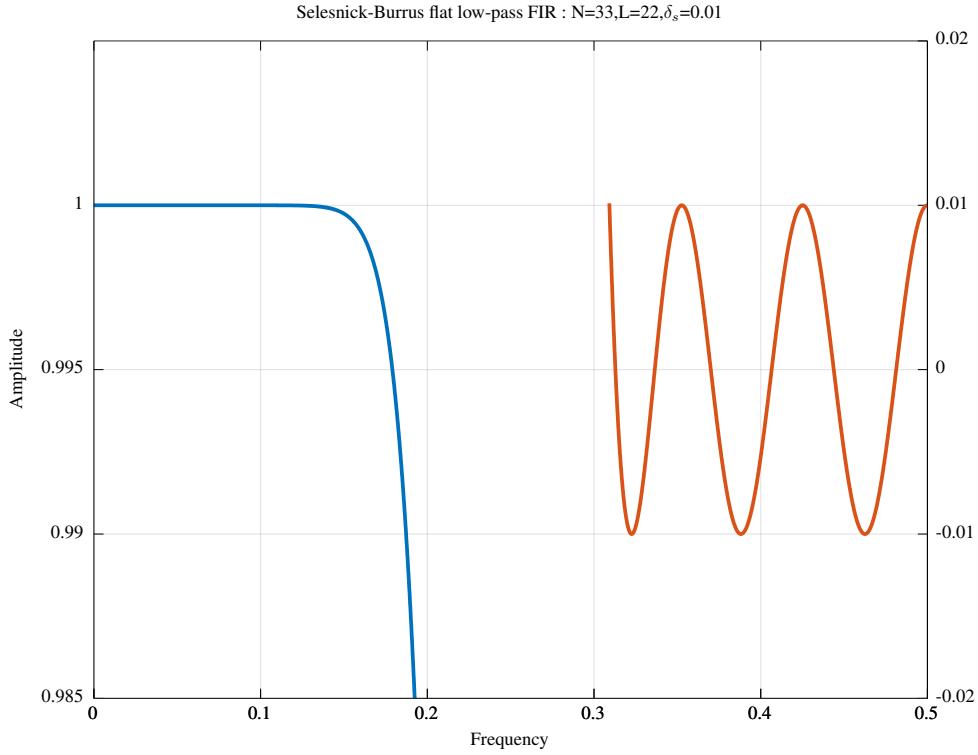

Figure L.27: Response of a mini-max FIR maximally-flat pass-band low-pass filter with fixed δ_s [56, Section II.B].

```
N=33 % Filter length
L=22 % Filter flat-ness
deltas=0.01 % Amplitude stop band peak ripple
```

Figure L.27 shows the pass-band and stop-band amplitude responses of the fixed δ_s filter. The Octave function *selesnickFIRsymmetric_flat_lowpass* uses Lagrange interpolation to find the filter amplitude response and removes spurious peaks in the pass-band amplitude response that are due to numerical errors.

L.5.2 Design of FIR band-pass filters with flat pass-bands and equi-ripple stop-bands

Selesnick and *Burrus* describe the design of maximally-flat pass-band, band-pass, FIR filters with centre frequency, ω_p , pass-band width $2\omega_t$ and upper and lower stop-band ripple δ_{su} and δ_{sl} , respectively. For maximally-flat band-pass FIR filters:

$$H_L(z) = \left[\frac{1 - 2z^{-1} \cos \omega_p + z^{-2}}{4} \right]^{\frac{L}{2}}$$

where L is a multiple of 4, N is odd. The amplitude response is:

$$A(\omega) = 1 + (-1)^{\frac{L}{2}} \left[\frac{\cos \omega_p - \cos \omega}{2} \right]^{\frac{L}{2}} A_M(\omega)$$

where A_M is the amplitude response of a symmetric FIR filter, H_M , of length $N - L$. *Selesnick* and *Burrus* describe exchange algorithms for the two cases:

1. specifies $N, L, \omega_p, \omega_t, K = \delta_{su}/\delta_{sl}$ and minimises δ_{sl}
2. specifies N, L, δ_{su} and δ_{sl} and maximises ω_t

The exchange algorithms described in this section place all extremal frequencies in the stop-bands. The *Remez* exchange algorithm requires that the error alternate in sign over the set of reference frequencies. Consequently, at each iteration, only one of the stop-band edges can be included in the set of reference frequencies.

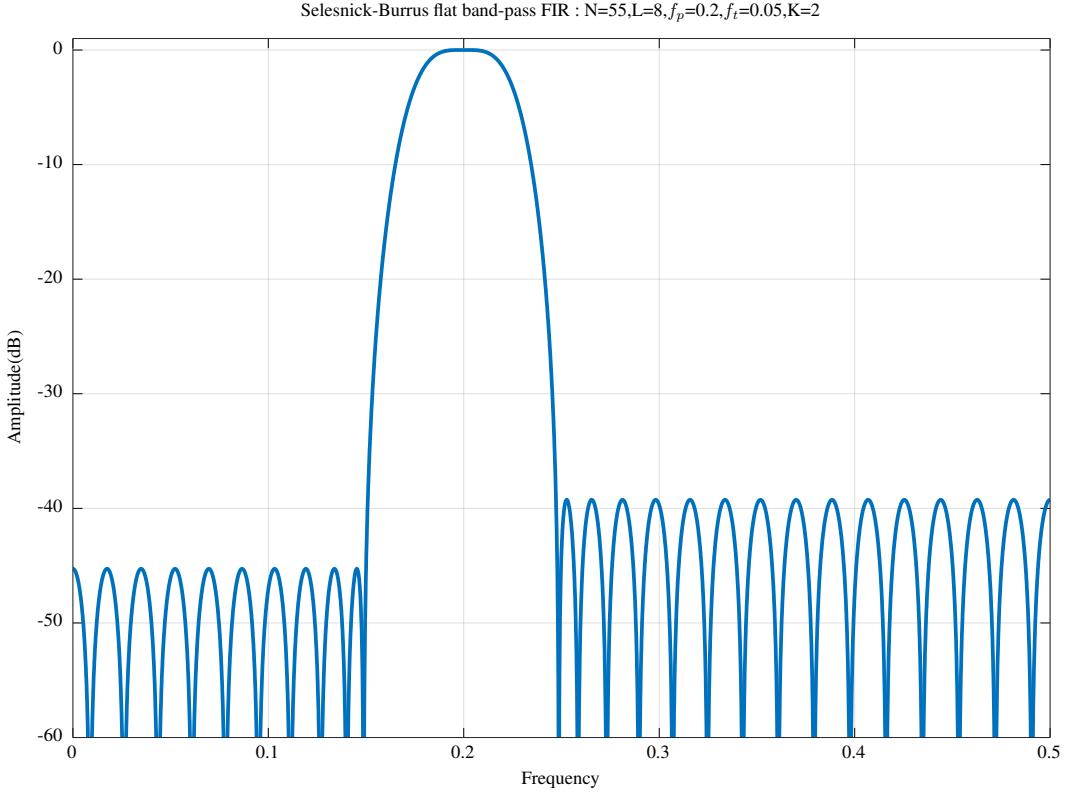

Figure L.28: Response of a mini-max FIR maximally-flat pass-band band-pass filter with fixed ω_p and ω_t [56, Section III].

Maximally-flat pass-band and fixed ω_p and ω_t

For convenience, set $\omega_a = \omega_p - \omega_t$ and $\omega_b = \omega_p + \omega_t$. In this case [56, Section III]:

The reference set is updated by the following procedure: First compute the set of all local extremal frequencies of $A(\omega)$ in $[0, \pi]$. Calling this set R , remove ω_p from R . R will then contain either $(N - L + 1)/2$ or $(N - L + 3)/2$ frequencies. If R contains $(N - L + 3)/2$ frequencies, then remove either 0 or π as follows: if $|A(\pi)| < K|A(0)|$ then remove π , otherwise remove 0. Next append either ω_a or ω_b to R : if $|A(\omega_b)| < K|A(\omega_a)|$ then append ω_a , otherwise append ω_b . R is the new reference set and has size $(N - L + 3)/2$. On each iteration, the filter H_M is found such that $A(\omega)$ interpolates $\delta_{sl}(-1)^k$ over the reference set frequencies in the first stop-band and $K\delta_{sl}(-1)^k$ in the second stop-band.

The Octave script *mcclellanFIRsymmetric_flat_bandpass_test.m* calls the Octave function *mcclellanFIRsymmetric* to design a maximally-flat FIR band-pass filter having fixed ω_p and ω_t and $K = \delta_{su}/\delta_{sl}$. The specification of the filter is:

```
N=55 % Filter length
L=8 % Filter flat-ness
fp=0.2 % Amplitude pass-band centre frequency
ft=0.05 % Amplitude pass-band half-width frequency
K=2 % Amplitude stop-band ripple ratio
nplot=4000 % Number of frequency points
maxiter=100 % Maximum iterations
tol=1e-08 % Tolerance on convergence
```

Figure L.28 shows the amplitude response of the fixed ω_p and ω_t filter. Figure L.29 shows the detailed pass-band and stop-band amplitude responses of the filter.

Maximally-flat pass-band and fixed δ_{su} and δ_{sl}

In the second case [56, Section III]:

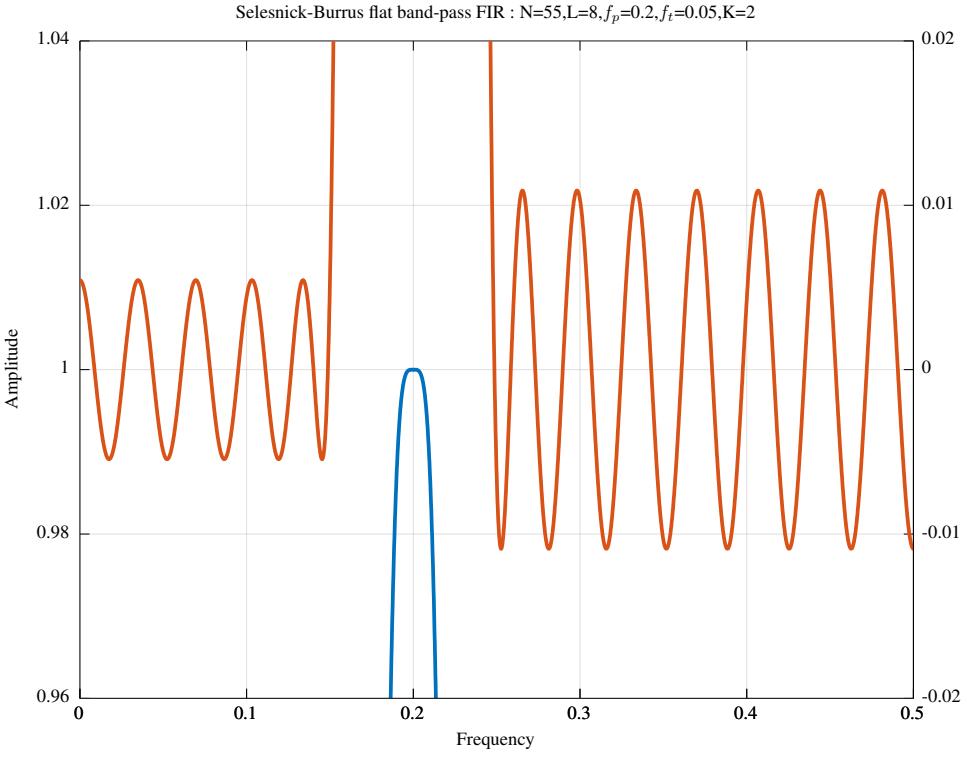

Figure L.29: Pass-band and stop-band responses of a mini-max FIR maximally-flat pass-band band-pass filter with fixed ω_p and ω_t [56, Section III].

A similar algorithm is used for approach (2) in which δ_{sl} and δ_{su} are specified and the stop-band edges are left variable. The reference set is updated in the same manner, except no stopband edge is appended to R . Let $\omega_1, \dots, \omega_q$ denote the reference set frequencies ordered in increasing order. On each iteration, the filter H_M is found such that:

$$\begin{aligned} A(\omega) &= \delta_{sl} (-1)^{k+c} && \text{for } \omega_k < \omega_p \\ A(\omega) &= \delta_{su} (-1)^{k+c+1} && \text{for } \omega_k > \omega_p \end{aligned}$$

where c equals 0 or 1, whichever gives $A(\omega) = -\delta_{sl}$ at the highest reference frequency less than ω_p .

The Octave script *selesnickFIRsymmetric_flat_bandpass_test.m* calls the Octave function *selesnickFIRsymmetric_flat_bandpass* to design a maximally-flat FIR low-pass filter having fixed δ_{su} and δ_{sl} . The specification of the filter is:

```
N=55 % Filter length
L=16 % Filter maximal flat-ness
deltasl=0.01 % Amplitude lower stop-band peak ripple
deltasu=0.02 % Amplitude upper stop-band peak ripple
fp=0.2 % Amplitude pass-band centre frequency
ft=0.04 % Initial amplitude pass-band half-width
nplot=4000 % Number of frequency
tol=1e-08 % Tolerance
```

Figure L.30 shows the pass-band and stop-band amplitude responses of the fixed δ_{su} and δ_{sl} filter.

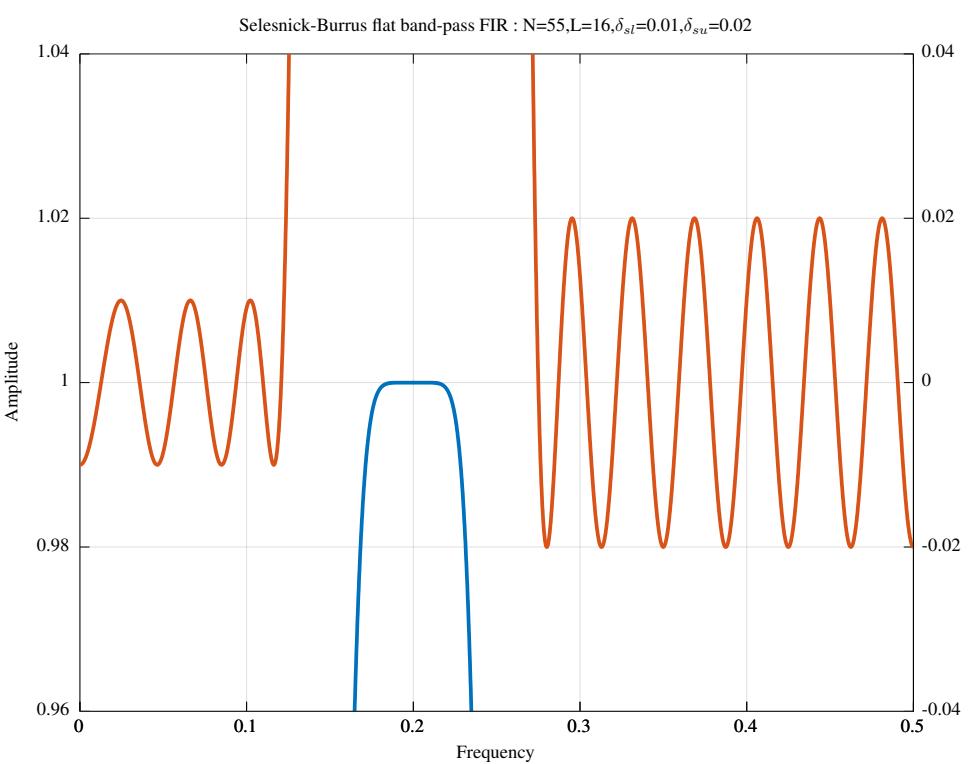

Figure L.30: Response of a mini-max FIR maximally-flat pass-band band-pass filter with fixed δ_{su} and δ_{sl} [56, Section III].

L.5.3 Design of FIR low-pass differentiators with equi-ripple stop-bands

L.6 Design of half-band FIR filters

L.6.1 Vaidyanathan's "TRICK" for the design of FIR half-band filters

Vaidyanathan and Nguyen [115] describe a method for the design of half-band FIR filters with pass-band edge f_p and length $4M + 3$:

1. Design a low-pass FIR filter, $G(z)$ with odd order $2M + 1$, pass band edge $2f_p$ and transition band $2f_p$ to 0.5
2. Construct the half-band FIR filter:

$$h(n) = \begin{cases} \frac{1}{2}g\left(\frac{n}{2}\right), & n = 0, 2, \dots, 4M + 2 \\ 0, & n = 1, 3, \dots, 4M + 1, \quad n \neq 2M + 1 \\ \frac{1}{2} & n = 2M + 1 \end{cases}$$

The z -domain transfer function of $H(z)$ is:

$$H(z) = \frac{G(z^2) + z^{-(2M+1)}}{2}$$

The Octave script `vaidyanathan_trick_test.m` designs a half-band filter with pass-band edge $fp = 0.24$ and $M = 80$ using Vaidyanathan's "TRICK". The script calls the Octave `remez` function to design a low-pass filter with pass-band edge $2fp = 0.48$ and stop-band edge 0.499. The `remez` function fails to converge for $M > 81$. Figure L.31 shows the frequency response of the filter.

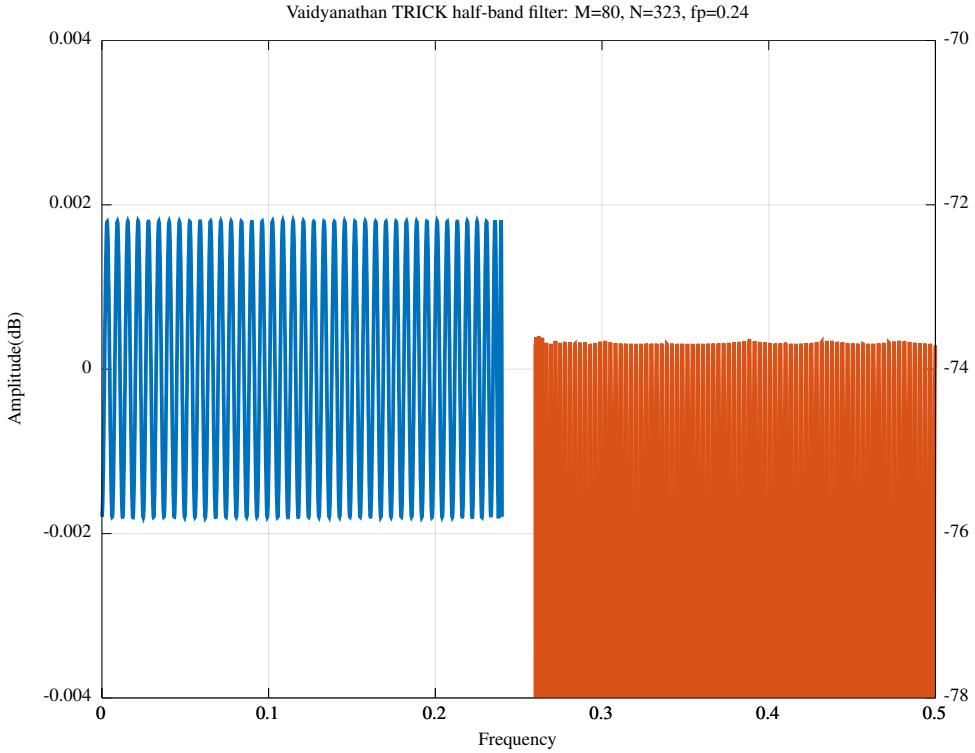

Figure L.31: FIR half-band filter with $fp = 0.24$ and $M = 80$ designed with Vaidyanathan's "TRICK" [115]

L.6.2 Design of equi-ripple FIR half-band filters

Zahradník, Vlček and Unbehauen [121] describe the closed-form design of almost-equiripple half-band FIR filters. The impulse response, h , of a length $4n + 3$ half-band FIR filter is defined by the transfer function:

$$H(z) = \sum_{l=0}^{4n+2} h_l z^{-l} \quad (\text{L.9})$$

where:

$$\begin{aligned} h_{2n+1} &= \frac{1}{2} \\ h_{2n+1 \pm 2l} &= 0, \quad l = 1, \dots, n \end{aligned}$$

Substituting $v = \frac{1}{2}(z + \frac{1}{z})$, the frequency response is:

$$H(e^{j\omega T}) = e^{-j(2n+1)\omega T} Q(\cos \omega T)$$

In particular, the pass-band edge is at $v_p = \cos \omega_p T$. Here $Q(v)$, the *zero-phase frequency response*, is:

$$Q(v) = \frac{1}{2} + \sum_{l=0}^n c(2l+1) T_{2l+1}(v) \quad (\text{L.10})$$

$T_l(x)$ is the *Chebyshev polynomial of the first kind*. Some properties of $T_l(x)$ are:

1. $T_l(\cos \theta) = \cos(l\theta)$
2. $T_0(x) = 1, T_1(x) = x, T_{l+1}(x) = 2xT_l(x) - T_{l-1}(x)$
3. $\frac{dT_l(x)}{dx} = lU_{l-1}(x)$

where $U_l(v)$ is the *Chebyshev polynomial of the second kind*. The coefficients, c , of the expansion of Q are the distinct symmetric FIR coefficients of the impulse response of H . Some properties of $U_l(x)$ are:

1. $U_l(\cos \theta) = \frac{\sin((l+1)\theta)}{\sin \theta}$
2. $U_{2l}(\cos \theta) = U_l(\cos 2\theta) + U_{l-1}(\cos 2\theta) = U_l(2\cos^2 \theta - 1) + U_{l-1}(2\cos^2 \theta - 1)^{\text{red}}$
3. $U_0(x) = 1, U_1(x) = 2x, U_{l+1}(x) = 2xU_l(x) - U_{l-1}(x)$

Vlček and Unbehauen [95, Section IV] show that the equivalent zero-phase response of an IIR filter is:

$$Q(v) = \frac{1}{1 + \varepsilon^2 F^2(v)}$$

The equiripple properties of $F(v)$ correspond to a differential equation that can be solved by elliptic integrals, giving a set of parametric equations for F and v in terms of Jacobian elliptic functions of a complex variable, u . With the choice of half-band FIR filter order, the solution of interest here is [95, Equations 33 and 34]:

$$\begin{aligned} F(u) &= \operatorname{cd}\left(\frac{Mu}{\kappa_1}, \kappa_1\right) \\ v &= \operatorname{dn}(u, \kappa) \end{aligned}$$

where $F(v) = \pm \frac{1}{\kappa_1}$ are the stop-band extremal values and κ_1 is the elliptic modulus. The complex parameter u follows the path shown in [95, Figure 8].

Zahradník et al. use the elliptic function identity

$$\operatorname{dn}^2(u, \kappa) = \kappa'^2 + (1 - \kappa'^2) \operatorname{cn}^2(u, \kappa)$$

d

$$U_{2l}(\cos \theta) = \frac{\sin[(2l+1)\theta] \cos \theta + \sin \theta \cos[(2l+1)\theta]}{2 \sin \theta \cos \theta} + \frac{\sin[(2l+1)\theta] \cos \theta - \sin \theta \cos[(2l+1)\theta]}{2 \sin \theta \cos \theta}$$

to give:

$$x = \frac{2v^2 - 1 - \kappa'^2}{1 - \kappa'^2} = 2 \operatorname{cn}^2(u, \kappa) - 1$$

Returning to the case of an almost-equiripple half-band FIR filter, Zahradník *et al.* [121, Section II] define $G(v) = U_{2n}(v)$ as the generating function for $Q(v)$:

$$Q(v) = \frac{1}{2} + \frac{1}{N} \int G(v) dv$$

where N is a normalising factor. Apparently by analogy with the equiripple IIR filter, Zahradník *et al.* [121, Equation 13] substitute x into the double angle identity for $U_{2n}(\cos \theta)$ and redefine the generating function as:

$$G(v) = U_n\left(\frac{2v^2 - 1 - \kappa'^2}{1 - \kappa'^2}\right) + U_{n-1}\left(\frac{2v^2 - 1 - \kappa'^2}{1 - \kappa'^2}\right)$$

Zahradník and Vlček [118, Equation 10] modify this to give a better equiripple approximation:

$$G(v) = AU_n\left(\frac{2v^2 - 1 - \kappa'^2}{1 - \kappa'^2}\right) + BU_{n-1}\left(\frac{2v^2 - 1 - \kappa'^2}{1 - \kappa'^2}\right)$$

Zahradník and Vlček [118, Equations 11 to 14] provide numerical approximations for n , κ' , A and B :

$$\begin{aligned} n &= \frac{a_s - 18.18840664\omega_p T + 33.64775300}{18.54155181\omega_p T - 29.13196871} \\ \kappa' &= \frac{n\omega_p T - 1.57111377n + 0.00665857}{-1.01927560n + 0.37221484} \\ A &= \left(0.01525753n + 0.03682344 + \frac{9.24760314}{n}\right)\kappa' + 1.01701407 + \frac{0.73512298}{n} \\ B &= \left(0.00233667n - 1.35418408 + \frac{5.75145813}{n}\right)\kappa' + 1.02999650 - \frac{0.72759508}{n} \end{aligned}$$

where $a_s < 0$ is the stop-band attenuation in dB. Alternatively, A and B can be obtained numerically by solving:

$$Q(v_p) = \begin{cases} Q(1), & \text{if } n \text{ is odd} \\ Q(v_{01}), & \text{if } n \text{ is even} \end{cases}$$

and:

$$\begin{aligned} Q(v_{01}) &= 1, & \text{if } n \text{ is odd} \\ Q(1) &= 1, & \text{if } n \text{ is even} \end{aligned}$$

where v_{01} is the first zero of the generating function $U_{2n}(\operatorname{cn}(u, \kappa))$ (ie: the first extremal value of $Q(v)$ as $1 \rightarrow v$) [121, Equation 15]:

$$v_{01} = \sqrt{\kappa'^2 + (1 - \kappa'^2) \cos^2 \frac{\pi}{2n+1}}$$

Writing:

$$U_n(v) = \int U_n\left(\frac{2v^2 - 1 - \kappa'^2}{1 - \kappa'^2}\right) dv$$

the zero-phase transfer function is:

$$Q(v) = \frac{1}{2} + \frac{A}{N} U_n(v) + \frac{B}{N} U_{n-1}(v)$$

The normalisation factor N is [118, Equation 17]:

$$N = \begin{cases} 2[AU_n(v_{01}) + BU_{n-1}(v_{01})], & \text{if } n \text{ is odd} \\ 2[AU_n(1) + BU_{n-1}(1)], & \text{if } n \text{ is even} \end{cases}$$

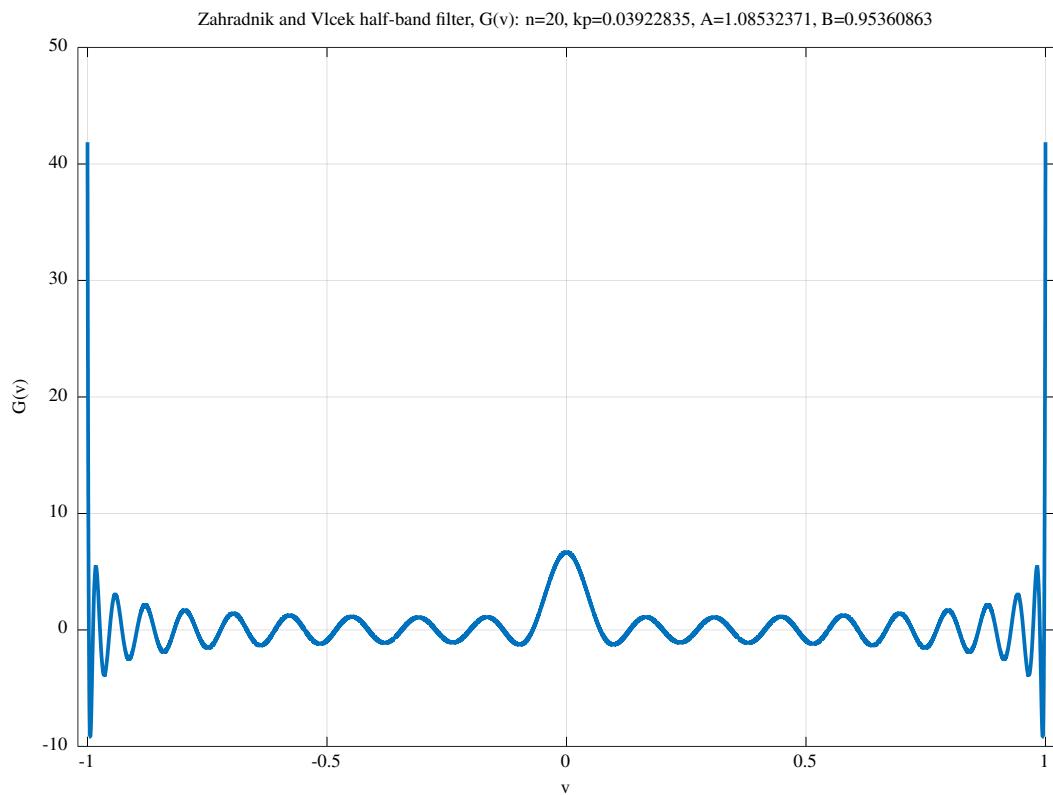

Figure L.32: Equiripple FIR half-band filter generating function, $G(v)$, for $n = 20$, $\kappa' = 0.03922835$, $A = 1.08532371$, $B = 0.95360863$ and $N = 0.55091994$ [118, Figure 1]

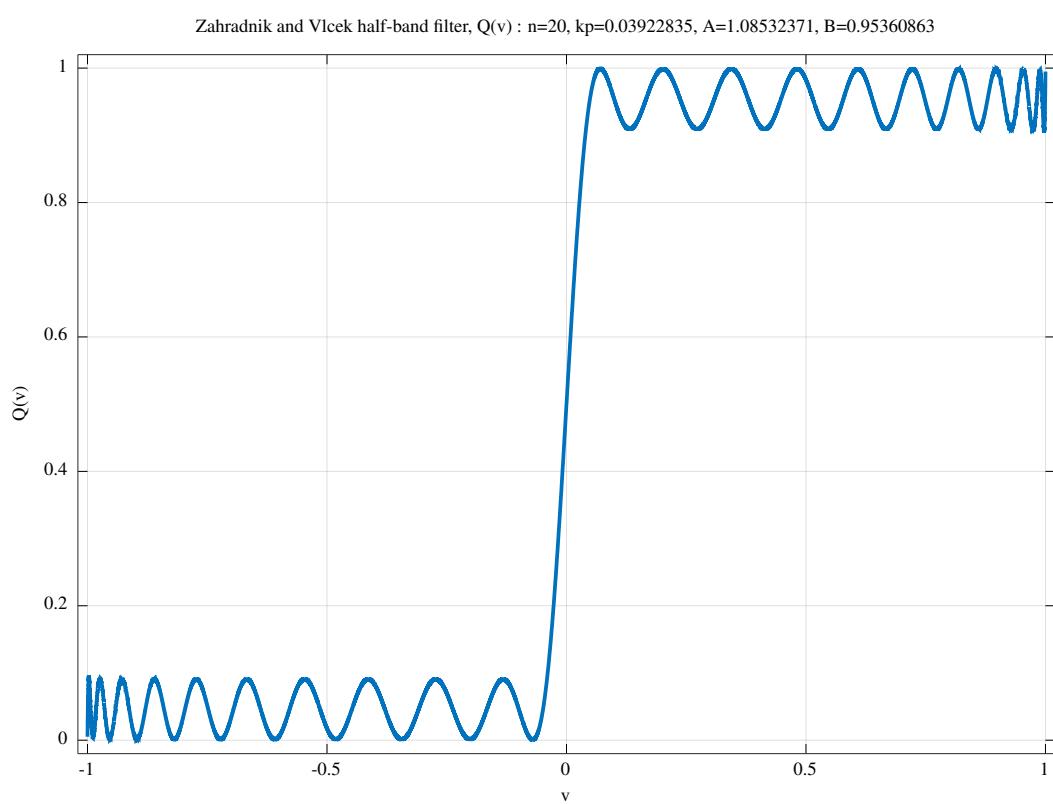

Figure L.33: Equiripple FIR half-band filter zero-phase frequency response, $Q(v)$, for $n = 20$, $\kappa' = 0.03922835$, $A = 1.08532371$, $B = 0.95360863$ and $N = 0.55091994$ [118, Figure 2]

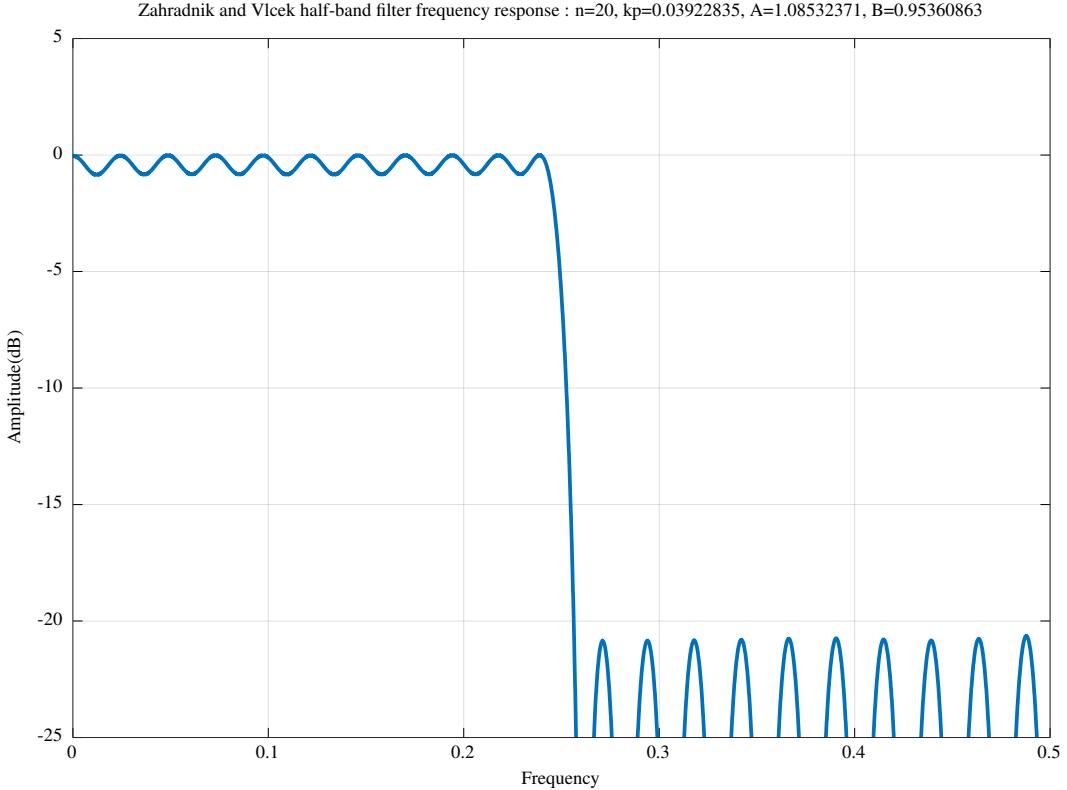

Figure L.34: Equiripple FIR half-band filter frequency response for $n = 20$, $\kappa' = 0.03922835$, $A = 1.08532371$, $B = 0.95360863$ and $N = 0.55091994$

Zahradník and Vlček [118, Figures 1 and 2] show plots of the generating function, $G(v)$ and zero-phase frequency response, $Q(v)$ for $n = 20$, $\kappa' = 0.03922835$, $A = 1.08532371$, $B = 0.95360863$ and $N = 0.55091994$. The Octave script *zahradnik_halfband_test.m* an reproduces these as Figure L.32 and Figure L.33. Figure L.34 shows the corresponding frequency response.

The Chebyshev polynomial of the second kind satisfies the differential equation:

$$(1 - x^2) \frac{d^2 U_n(x)}{dx^2} - 3x \frac{dU_n(x)}{dx} + n(n+2) U_n(x) = 0 \quad (\text{L.11})$$

Substituting x [118, Equation 8]:

$$v(v^2 - \kappa'^2) \left[(1 - v^2) \frac{d^2 U_n(v)}{dv^2} - 3v \frac{dU_n(v)}{dv} \right] + [(\kappa'^2 + 2v^2)(1 - v^2)] \frac{dU_n(v)}{dv} + 4v^3 n(n+2) U_n(v) = 0 \quad (\text{L.12})$$

Equation L.12 is arranged so that its solution is simplified by using Equation L.11. Equation L.12 is solved by the series expansion:

$$U_n \left(\frac{2v^2 - 1 - \kappa'^2}{1 - \kappa'^2} \right) = \sum_{l=0}^n \alpha_{2l} U_{2l}(v) \quad (\text{L.13})$$

Integrating this expansion results in an expression of the form shown in Equation L.10. Zahradník and Vlček [118, Table 1] show an algorithm for the evaluation of the coefficients, a_l , of U_n , reproduced here, with a correction to α_{2n-4} , as Algorithm L.3.

The Octave script *zahradnik_halfband_test.m* implements the design of an equiripple FIR half-band filter using Algorithm L.3. The pass-band edge is $f_p = 0.240$, the stop-band attenuation is $a_s = -140\text{dB}$ and $n = 118$ for a filter length of 475. The value of n given by Equation 11 of Zahradník and Vlček [118] is increased slightly. The values of A and B are found by a “brute-force” search of all the extremal values in the pass-band. Figure L.35 shows the amplitude response of the half-band FIR filter. The distinct coefficients of the half-band filter are (see Equation L.9):

```

Figure L.35: Equiripple FIR half-band filter with $f_p = 0.240$ and $a_s = -140\text{dB}$ and $n = 118$ calculated by Algorithm L.3 [118, Table 1]

Addendum

Working for Zahradník and Vlček Equation 8 [118]

The chain rule gives:

$$\begin{aligned}\frac{dU}{dv} &= \frac{dU}{dx} \frac{dx}{dv} \\ \frac{d^2U}{dv^2} &= \frac{d^2U}{dx^2} \left(\frac{dx}{dv} \right)^2 + \frac{dU}{dx} \frac{d^2x}{dv^2}\end{aligned}$$

where:

$$\begin{aligned}\frac{dx}{dv} &= \frac{4v}{1 - \kappa'^2} \\ \frac{d^2x}{dv^2} &= \frac{4}{1 - \kappa'^2}\end{aligned}$$

Rearranging:

$$\begin{aligned}x \frac{dU}{dx} &= x \left(\frac{dx}{dv} \right)^{-1} \frac{dU}{dv} = \frac{2v^2 - 1 - \kappa'^2}{4v} \frac{dU}{dv} \\ (1 - x^2) \frac{d^2U}{dx^2} &= (1 - x^2) \left(\frac{dx}{dv} \right)^{-2} \left[\frac{d^2U}{dv^2} - \left(\frac{dx}{dv} \right)^{-1} \frac{d^2x}{dv^2} \frac{dU}{dv} \right] \\ &= \frac{(1 - v^2)(v^2 - \kappa'^2)}{4v^2} \left[\frac{d^2U}{dv^2} - \frac{1}{v} \frac{dU}{dv} \right]\end{aligned}$$

Substituting into Equation L.11 gives Equation L.12.

Working for Zahradník and Vlček Table 1 [118, Appendix and Table 1]

Equations 18 to 25 are experimentally confirmed in the Octave script *chebyshevU_test.m* under the assumption that $U_l(v) = 0$ for $l \leq 0$.

Working for Equation 25

$$\begin{aligned}
U_{l+3}(v) &= 2vU_{l+2}(v) - U_{l+1}(v) \\
&= 2v(2vU_{l+1}(v) - U_l(v)) - U_{l+1}(v) \\
&= 4v^2(2vU_l(v) - U_{l-1}(v)) - (2vU_l(v) - U_{l-1}(v)) - U_{l+1}(v) - U_{l-1}(v) \\
&= 8v^3U_l(v) - 4v^2U_{l-1}(v) - 2U_{l+1}(v) - U_{l-1}(v) \\
4v^2U_{l-1}(v) &= 2v(2vU_{l-1}(v) - U_{l-2}(v)) + 2vU_{l-2}(v) \\
&= 2vU_l(v) - U_{l-1} + U_{l-2} + 2vU_{l-2}(v) - U_{l-3}(v) + U_{l-3}(v) \\
&= U_{l+1}(v) + 2U_{l-1}(v) + U_{l-3}(v)
\end{aligned}$$

Finally,

$$8v^3U_l(v) = U_{l+3}(v) + 3U_{l+1}(v) + 3U_{l-1}(v) + U_{l-3}(v)$$

Substituting Equation L.13 gives the result.

Working for Equation 23

Equation 23 is simplified by applying Equation 6.

$$\begin{aligned}
-v \left[(1-v^2) \frac{d^2U_{2l}(v)}{dv^2} - 3v \frac{dU_{2l}(v)}{dv} \right] &= 4l(l+1)vU_{2l}(v) \\
&= 2l(l+1)[U_{2l+1}(v) + U_{2l-1}(v)] \\
v^3 \left[(1-v^2) \frac{d^2U_{2l}(v)}{dv^2} - 3v \frac{dU_{2l}(v)}{dv} \right] &= -4l(l+1)v^3U_{2l}(v) \\
&= -\frac{1}{2}l(l+1)[U_{2l+3}(v) + 3U_{2l+1}(v) + 3U_{2l-1}(v) + U_{2l-3}(v)]
\end{aligned}$$

Working for Equation 24

For the κ'^2 part of Equation 24:

$$\begin{aligned}
4v^2U_l(v) &= 2v(2vU_l(v) - U_{l-1}(v)) + 2vU_{l-1}(v) - U_{l-2}(v) + U_{l-2}(v) \\
&= 2vU_{l+1}(v) - U_l(v) + 2U_l(v) + U_{l-2}(v) \\
&= U_{l+2}(v) + 2U_l(v) + U_{l-2}(v) \\
4(1-v^2)U_l(v) &= -[U_{l+2}(v) - 2U_l(v) + U_{l-2}(v)]
\end{aligned}$$

Using Equation 20:

$$\begin{aligned}
(1-v^2) \frac{dU_{2l}(v)}{dv} &= \sum_{p=0}^l 4p(1-v^2)U_{2p-1}(v) \\
&= -\sum_{p=0}^l p[U_{2p+1}(v) - 2U_{2p-1}(v) + U_{2p-3}(v)] \\
&= -\left[\sum_{p=1}^{l+1} (p-1)U_{2p-1}(v) - \sum_{p=0}^l 2pU_{2p-1}(v) + \sum_{p=-1}^{l-1} (p+1)U_{2p-1}(v) \right] \\
&= -[lU_{2l+1}(v) + (l-1)U_{2l-1}(v) - 2lU_{2l-1}(v)] \\
&= (l+1)U_{2l-1}(v) - lU_{2l+1}(v)
\end{aligned}$$

Similarly, for the $2v^2(1-v^2)$ part of Equation 24:

$$\begin{aligned}
2v^2(1-v^2) \frac{dU_{2l}(v)}{dv} &= 2v^2 \sum_{p=0}^l 4p(1-v^2)U_{2p-1}(v) \\
&= 2v^2[(l+1)U_{2l-1}(v) - lU_{2l+1}(v)] \\
&= \frac{l+1}{2}[U_{2l+1}(v) + 2U_{2l-1}(v) + U_{2l-3}(v)] - \frac{l}{2}[U_{2l+3}(v) + 2U_{2l+1}(v) + U_{2l-1}(v)]
\end{aligned}$$

Working for Equation 26 Collecting terms in $U_{2l+3}(v)$ from Equation 23:

$$-\frac{1}{2}l(l+1)\alpha_{2l}$$

Collecting terms in $U_{2l+3}(v)$ from Equation 24:

$$-\frac{1}{2}l\alpha_{2l}$$

Collecting terms in $U_{2l+3}(v)$ from Equation 25:

$$\frac{1}{2}n(n+2)\alpha_{2l}$$

Giving:

$$U_{2l+3}(v) : \frac{1}{2}[n(n+2) - l(l+2)]\alpha_{2l}$$

Working for Equation 27 Collecting terms in $U_{2l+1}(v)$ from Equation 23:

$$-\frac{3}{2}l(l+1)\alpha_{2l} + 2l(l+1)\kappa'^2\alpha_{2l}$$

Collecting terms in $U_{2l+1}(v)$ from Equation 24:

$$-l\kappa'^2\alpha_{2l} + \frac{1}{2}[(l+1) - 2l]\alpha_{2l}$$

Collecting terms in $U_{2l+1}(v)$ from Equation 25:

$$\frac{3}{2}n(n+2)\alpha_{2l}$$

Giving:

$$U_{2l+1}(v) : \frac{1}{2}[3(n(n+2) - l(l+2)) + 2l + 1]\alpha_{2l} + l(2l+1)\kappa'^2\alpha_{2l}$$

Working for Equation 28 Collecting terms in $U_{2l-1}(v)$ from Equation 23:

$$-\frac{3}{2}l(l+1)\alpha_{2l} + 2l(l+1)\kappa'^2\alpha_{2l}$$

Collecting terms in $U_{2l-1}(v)$ from Equation 24:

$$(l+1)\kappa'^2\alpha_{2l} + \frac{1}{2}[2(l+1) - l]\alpha_{2l}$$

Collecting terms in $U_{2l-1}(v)$ from Equation 25:

$$\frac{3}{2}n(n+2)\alpha_{2l}$$

Giving:

$$U_{2l-1}(v) : \frac{1}{2}[3(n(n+2) - l(l+2)) + 2(2l+1)]\alpha_{2l} + (l+1)(2l+1)\kappa'^2\alpha_{2l}$$

Working for Equation 29 Collecting terms in $U_{2l-3}(v)$ from Equation 23:

$$-\frac{1}{2}l(l+1)\alpha_{2l}$$

Collecting terms in $U_{2l-3}(v)$ from Equation 24:

$$\frac{1}{2}(l+1)\alpha_{2l}$$

Collecting terms in $U_{2l-3}(v)$ from Equation 25:

$$\frac{1}{2}n(n+2)\alpha_{2l}$$

Giving:

$$U_{2l-3}(v) : \frac{1}{2}[n(n+2) - (l-1)(l+1)]\alpha_{2l}$$

Working for Equations 30 to 33 Changing the summation variables:

$$\begin{aligned}
& \sum_{l=3}^{n+3} \frac{1}{2} [n(n+2) - (l-3)(l-1)] \alpha_{2l-6} U_{2l-3}(v) \dots \\
& + \sum_{l=2}^{n+2} \left\{ \frac{1}{2} [3(n(n+2) - (l-2)l) + 2l-3] + (l-2)(2l-3)\kappa'^2 \right\} \alpha_{2l-4} U_{2l-3}(v) \dots \\
& + \sum_{l=1}^{n+1} \left\{ \frac{1}{2} [3(n(n+2) - (l-1)(l+1)) + 2(2l-1)] + l(2l-1)\kappa'^2 \right\} \alpha_{2l-2} U_{2l-3}(v) \dots \\
& + \sum_{l=0}^n \frac{1}{2} [n(n+2) - (l-1)(l+1)] \alpha_{2l} U_{2l-3}(v) \\
& = 0
\end{aligned}$$

Assuming that $U_l(v) = 0$ for $l \leq 0$:

$$\begin{aligned}
& \sum_{l=3}^{n+3} [n(n+2) - (l-3)(l-1)] \alpha_{2l-6} \dots \\
& + \sum_{l=2}^{n+2} [3(n(n+2) - (l-2)l) + 2l-3 + 2(l-2)(2l-3)\kappa'^2] \alpha_{2l-4} \dots \\
& + \sum_{l=2}^{n+1} [3(n(n+2) - (l-1)(l+1)) + 2(2l-1) + 2l(2l-1)\kappa'^2] \alpha_{2l-2} \dots \\
& + \sum_{l=2}^n [n(n+2) - (l-1)(l+1)] \alpha_{2l} \\
& = 0
\end{aligned} \tag{L.14}$$

The recurrence is initialised by calculating α_{2n} from the $n+3$ term, α_{2n-2} from the $n+2$ term and α_{2n-4} from the $n+1$ term in Equation L.14. The remaining terms $\alpha_{2n-6} \dots \alpha_0$ are calculated by backwards recurrence for $l = n, n-1, \dots, 3$. Equation L.14 is implemented in the *body* of Table 1.

Working for Equations 34 and 35 The $n+3$ term in L.14 gives:

$$[n(n+2) - l(l+2)] \alpha_{2n} = 0$$

α_{2n} is a free variable. Zahradník and Vlček choose $\alpha_{2n} = (1 - \kappa'^2)^{-n}$.

Working for Equation 36 The $n+2$ term in L.14 gives:

$$\begin{aligned}
& \frac{1}{2} [n(n+2) - (n-1)(n+1)] \alpha_{2n-2} + \left\{ \frac{1}{2} [3(n(n+2) - n(n+2)) + 2n+1] + n(2n+1)\kappa'^2 \right\} \alpha_{2n} = 0 \\
& [n(n+2) - (n-1)(n+1)] \alpha_{2n-2} + [2n+1 + 2n(2n+1)\kappa'^2] \alpha_{2n} = 0 \\
& (2n+1) \alpha_{2n-2} + [2n+1 + 2n(2n+1)\kappa'^2] \alpha_{2n} = 0 \\
& \alpha_{2n-2} + [1 + 2n\kappa'^2] \alpha_{2n} = 0
\end{aligned}$$

Working for Equation 37 The $n+1$ term in L.14 gives:

$$\begin{aligned}
& \frac{1}{2} [n(n+2) - (n-2)n] \alpha_{2n-4} + \dots \\
& \left\{ \frac{1}{2} [3(n(n+2) - (n-1)(n+1)) + 2n-1] + (n-1)(2n-1)\kappa'^2 \right\} \alpha_{2n-2} + \dots \\
& \left\{ \frac{1}{2} [3(n(n+2) - n(n+2)) + 2(2n+1)] + (n+1)(2n+1)\kappa'^2 \right\} \alpha_{2n} = 0 \\
& 2n\alpha_{2n-4} + [4n+1 + (n-1)(2n-1)\kappa'^2] \alpha_{2n-2} + (2n+1)[(n+1)\kappa'^2 + 1]\alpha_{2n} = 0
\end{aligned}$$

L.7 Design of equi-ripple FIR filters with Zolotarev polynomials

The *Zolotarev* polynomials are an extension of the *Chebyshev* polynomials that have found applications in the design of narrow-band FIR filters [96, 169, 117]. Zahradník [117] shows that the Zolotarev polynomials can provide a closed-form design of an FIR low-pass filter with an “almost” equi-ripple approximation in two separate frequency bands. Appendix B reviews the notation for *Legendre*’s elliptic integrals and *Jacobi*’s elliptic functions.

L.7.1 The Zolotarev polynomials

Chen and Parks [169, Section II], define “a Zolotarev polynomial of degree N , with L zeros in the interval (α, β) and $N - L$ zeros in the interval $(-1, 1)$. The function value oscillates between -1 and $+1$ in both intervals $[\alpha, \beta]$ and $[-1, 1]$, and is larger than unity in the interval $(1, \alpha)$. It has $N - L + 1$ extremal points of value $+1$ or -1 in $[-1, 1]$ and $L + 1$ extremal points of value $+1$ or -1 in $[\alpha, \beta]$. The closed-form expression for a Zolotarev polynomial uses elliptic functions. It has three independent parameters: degree N , the number of zeros L in (α, β) , and the elliptic function modulus κ ”. Denoting such a polynomial by $f_{N,L}(u, \kappa)$, in parametric form [96, Equations 3 and 4]:

$$x = \frac{\operatorname{sn}^2(u, \kappa) + \operatorname{sn}^2\left(\frac{LK}{N}, \kappa\right)}{\operatorname{sn}^2(u, \kappa) - \operatorname{sn}^2\left(\frac{LK}{N}, \kappa\right)} \quad (\text{L.15})$$

$$f_{N,L}(u, \kappa) = \frac{(-1)^L}{2} \left[\left\{ \frac{H\left(u - \frac{LK}{N}, \kappa\right)}{H\left(u + \frac{LK}{N}, \kappa\right)} \right\}^N + \left\{ \frac{H\left(u + \frac{LK}{N}, \kappa\right)}{H\left(u - \frac{LK}{N}, \kappa\right)} \right\}^N \right] \quad (\text{L.16})$$

where κ is the *elliptic modulus*, $K = F\left(\frac{\pi}{2}, \kappa\right)$ and $H(u, \kappa)$ is the *Jacobi Eta* function. The complex variable u follows the path [169, Figure 2]:

- $u \in [0, iK']$ maps to $x \in [-1, 1]$
- $u \in [iK', K + iK']$ maps to $x \in [1, \alpha]$
- $u \in [K + iK', K]$ maps to $x \in [\alpha, \beta]$

Vlček and Unbehauen [96] prefer the notation $Z_{p,q}(w, \kappa)$ where p counts the number of zeros to the right of the maximum, q counts the number of zeros to the left and Vlček and Unbehauen introduce the independent variable w , related to the discrete-time z -domain by:

$$w = \frac{1}{2} (z + z^{-1})|_{z=e^{i\omega T}} = \cos \omega T$$

The intervals $x \in (-1, 1) \cup (\alpha, \beta)$ are transformed from the x -domain to the w -domain intervals $(-1, w_s) \cup (w_p, 1)$ by [96, Equation 6]:

$$w = x \operatorname{cn}^2(u_0, \kappa) - \operatorname{sn}^2(u_0, \kappa) \quad (\text{L.17})$$

$$= \frac{\operatorname{sn}^2(u, \kappa) \operatorname{cn}^2(u_0, \kappa) + \operatorname{cn}^2(u, \kappa) \operatorname{sn}^2(u_0, \kappa)}{\operatorname{sn}^2(u, \kappa) - \operatorname{sn}^2(u_0, \kappa)} \quad (\text{L.18})$$

where $u_0 = \frac{p}{p+q} K(\kappa)$. The inverse transformation is [169, Equation 2] [36, Section 22.6(iv)]:

$$\begin{aligned} u &= \operatorname{arcsc} \left(\operatorname{i sc}(u_0, \kappa) \sqrt{\frac{1+w}{1-w}}, \kappa \right) \\ &= \operatorname{i arcsn} \left(\operatorname{sc}(u_0, \kappa) \sqrt{\frac{1+w}{1-w}}, \sqrt{1-\kappa^2} \right) \end{aligned} \quad (\text{L.19})$$

The extremal values of the Zolotarev polynomial $Z_{p,q}(w, \kappa)$ of degree $n = p + q$ alternate between -1 and 1 $p + 1$ times in the interval $(-1, w_s)$ and $q + 1$ times in the interval $(w_p, 1)$.

For convenience, Zahradník et al. [119, Equation 7] rewrite Equation L.16 as:

$$Z_{p,q}(u, \kappa) = (-1)^p \cosh \left\{ n \log \left[\frac{H(u + u_0, \kappa)}{H(u - u_0, \kappa)} \right] \right\}$$

Alternatively, the Zolotarev polynomials can be expressed in terms of the Chebyshev polynomials of the first kind, $T_n(\cos \Phi) = \cos n\Phi$ [96, Equations 26 and 27]:

$$\begin{aligned} Z_{p,q}(u, \kappa) &= (-1)^p T_{p+q}(\cos \Phi(u, \kappa)) \\ \cos \Phi(u, \kappa) &= \frac{1}{2} \left[\frac{H(u + u_0, \kappa)}{H(u - u_0, \kappa)} + \frac{H(u - u_0, \kappa)}{H(u + u_0, \kappa)} \right] \end{aligned} \quad (\text{L.20})$$

Whittaker and Watson [32, Page 480] define the *Jacobi Eta* function as:

$$H(u, \kappa) = -iq^{-\frac{1}{4}} e^{\frac{i\pi u}{2K}} \Theta(u + iK', \kappa) \quad (\text{L.21})$$

where $\Theta(u, \kappa)$ is the *Jacobi Theta* function, an even function with period $2K + i2K'$. Chen and Parks [169, Appendix, Equation A3] show (with confusing typesetting) that in the central lobe of the Zolotarev polynomial, for which $u = \sigma + iK'$ with $\sigma \in [0, K]$:

$$\left\{ \frac{H(u + u_0, \kappa)}{H(u - u_0, \kappa)} \right\}^n = (-1)^p \left\{ \frac{\Theta(\sigma + u_0, \kappa)}{\Theta(\sigma - u_0, \kappa)} \right\}^n$$

The maximiser of the Zolotarev polynomial in the central lobe is [169, Appendix]:

$$u_m = \sigma_m + iK'$$

where:

$$\begin{aligned} \kappa' &= \sqrt{1 - \kappa^2} \\ K' &= F\left(\frac{\pi}{2}, \kappa'\right) \\ \sigma_m &= \operatorname{arcsn}\left(\left[\frac{Z(u_0, \kappa)}{\kappa^2 \operatorname{sn}(u_0, \kappa) [\operatorname{cn}(u_0, \kappa) \operatorname{dn}(u_0, \kappa) + \operatorname{sn}(u_0, \kappa) Z(u_0, \kappa)]}\right]^{\frac{1}{2}}, \kappa\right) \end{aligned} \quad (\text{L.22})$$

and $Z(u, \kappa)$ is the *Jacobi Zeta* function. The corresponding maximum value is:

$$f_m = (-1)^p \cosh \left[n \log \frac{\Theta(\sigma_m + u_0, \kappa)}{\Theta(\sigma_m - u_0, \kappa)} \right] \quad (\text{L.23})$$

The Octave script *zolotarev_vlcek_unbehauen_test.m* calculates $Z_{5,9}(w, 0.78)$, shown as Figure 1 by Vlček and Unbehauen [96] and shown here as Figure L.36.

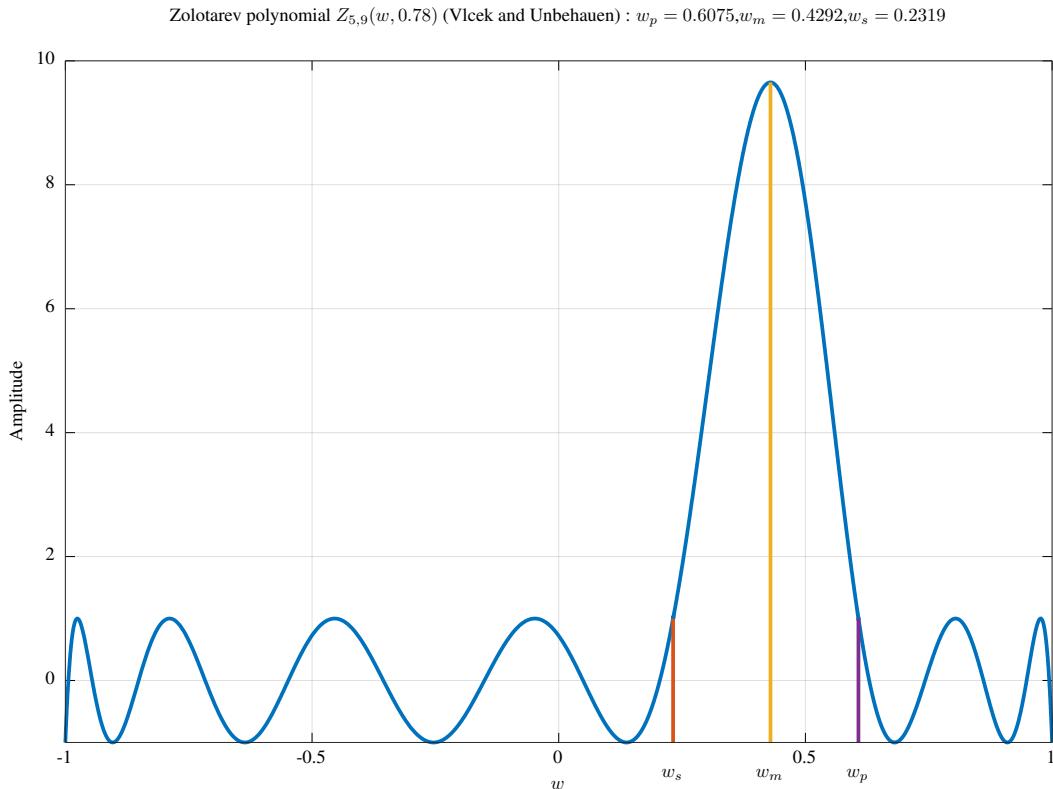

Figure L.36: Zolotarev polynomial $Z_{5,9}(u, 0.78)$

Following *Levy* [132, Equation 28] or *Vlček* and *Unbehauen* [95, Equations 22 and 23], *Vlček* and *Unbehauen* assert that, by inspection, the Zolotarev polynomials, $Z_{p,q}(w, \kappa)$, satisfy the following differential equation [96, Equation 7]:

$$(1 - w^2)(w - w_p)(w - w_s) \left(\frac{df}{dw} \right)^2 = n^2 (1 - f^2)(w - w_m)^2 \quad (\text{L.24})$$

Quoting *Vlček* and *Zahradník* [100, Section III]: “This nonlinear differential equation expresses the fact that the first derivative $Z'_{p,q}(w, \kappa)$ does not vanish at the points $w = \pm 1, w_p, w_s$, where $Z_{p,q}(w, \kappa) = \pm 1$ for which the right hand side of eq. (3) vanishes, and that $w = w_m$ is a turning point corresponding to the local extrema at which $Z_{p,q}(w, \kappa) \neq \pm 1$.” *Levy* [132] and *Vlček* and *Unbehauen* [96] show the solution of this non-linear differential equation with elliptic functions. Alternatively, differentiating Equation L.24 gives the following linear second-order differential equation [96, Equation 63]:

$$g_2(w) \left[(1 - w^2) \frac{d^2f}{dw^2} - w \frac{df}{dw} \right] - (1 - w^2) g_1(w) \frac{df}{dw} + n^2 g_0(w) f = 0 \quad (\text{L.25})$$

where:

$$\begin{aligned} g_2(w) &= (w - w_p)(w - w_s)(w - w_m) \\ g_1(w) &= (w - w_p)(w - w_s) - (w - w_m) \left(w - \frac{w_p + w_s}{2} \right) \\ g_0(w) &= (w - w_m)^3 \end{aligned} \quad (\text{L.26})$$

This differential equation can be solved by substituting the power series:

$$f(w) = \sum_{m=0}^n b_m w^m$$

Vlček and *Unbehauen* summarise the resulting recurrence relations in [96, Table IV], reproduced here (with corrections [97]) as Algorithm L.4.

The power series b_m coefficients of $Z_{5,15}(u, 0.77029)$ found with Algorithm L.4 are:

```
b_5_15 = [ -0.935306,      7.261946,      197.181637,     -497.153495, ...
           -6876.186281,    9666.711688,    92878.149607,   -82519.667919, ...

            -0.0430236735, -0.0262222295,  0.0032905111,  0.0269417021, ...
            0.0320251989,  0.0184629608, -0.0029739578, -0.0187425987, ...
            -0.0531541684 ];
```

Vlček and *Unbehauen* also show the expansion of $Z_{p,q}(w, \kappa)$ in Chebyshev polynomials of the first kind, $T_m(w)$:

$$f(w) = \sum_{m=0}^n a_m T_m(w)$$

The resulting recurrence relations are shown in Algorithm L.5 [96, Table V with corrections]^e.

^eThe Maxima script *zolotarev_vlcek_unbehauen_table_v.max* and my working by hand did not reproduce Table V of *Vlček* and *Unbehauen* [96, 97]. However, the Octave script *zolotarev_vlcek_unbehauen_test.m* shows that, for $\kappa = 0.78$, $p = 5$ and $q = 9$, my Algorithm L.4 and Algorithm L.5 produce, to within round-off error, the same Zolotarev polynomial as the calculation using elliptic functions in the Octave function *zolotarev_chen_parks.m*.

Algorithm L.4 *Vlček and Unbehauen's backwards recursion for $Z_{p,q}(w) = \sum_{m=0}^n b_m w^m (w)$* [96, Table IV], [97]

Require: p, q and κ

Initialisation:

$$n = p + q$$

$$u_0 = \frac{p}{p+q} K(\kappa)$$

$$w_p = 2 \operatorname{cd}^2(u_0, \kappa) - 1$$

$$w_s = 2 \operatorname{cn}^2(u_0, \kappa) - 1$$

$$w_q = \frac{w_p + w_s}{2}$$

$$w_m = w_s + 2 \frac{\operatorname{sn}(u_0, \kappa) \operatorname{cn}(u_0, \kappa)}{\operatorname{dn}(u_0, \kappa)} Z(u_0, \kappa)$$

$$\beta_n = 1, \beta_{n+1} = \beta_{n+2} = \beta_{n+3} = \beta_{n+4} = 0$$

Body:

for $m = n + 2$ **down to** 3 **do**

$$d_1 = (m + 2)(m + 1) w_p w_s w_m$$

$$d_2 = -(m + 1)(m - 1) w_p w_s - (m + 1)(2m + 1) w_m w_q$$

$$d_3 = w_m (n^2 w_m^2 - m^2 w_p w_s) + m^2 (w_m - w_q) + 3m(m - 1) w_q$$

$$d_4 = (m - 1)(m - 2)(w_p w_s - w_m w_q - 1) - 3w_m \left[n^2 w_m - (m - 1)^2 w_q \right]$$

$$d_5 = (2m - 5)(m - 2)(w_m - w_q) + 3w_m \left[n^2 - (m - 2)^2 \right]$$

$$d_6 = n^2 - (m - 3)^2$$

$$\beta_{m-3} = \frac{1}{d_6} \sum_{\mu=1}^5 d_\mu \beta_{m+3-\mu}$$

end for

Normalisation:

$$s_n = \sum_{m=0}^n \beta_m$$

for $m = 0$ **to** n **do**

$$b_m = (-1)^p \frac{\beta_m}{s_n}$$

end for

Algorithm L.5 Modified Vlček and Unbehauen backwards recursion for $Z_{p,q}(w) = \sum_{m=0}^n a_m T_m(w)$ [96, Table V], [97]

Require: p, q and κ

Initialisation:

$$n = p + q$$

$$u_0 = \frac{p}{p+q} K(\kappa)$$

$$w_p = 2 \operatorname{cd}^2(u_0, \kappa) - 1$$

$$w_s = 2 \operatorname{cn}^2(u_0, \kappa) - 1$$

$$w_q = \frac{w_p + w_s}{2}$$

$$w_m = w_s + 2 \frac{\operatorname{sn}(u_0, \kappa) \operatorname{cn}(u_0, \kappa)}{\operatorname{dn}(u_0, \kappa)} Z(u_0, \kappa)$$

$$\alpha_n = 1, \alpha_{n+1} = \alpha_{n+2} = \alpha_{n+3} = \alpha_{n+4} = \alpha_{n+5} = 0$$

Body:

for $m = n + 2$ **down to** 3 **do**

$$c_7 = n^2 - (m - 3)^2$$

$$c_6 = 2 [(m - 2)(m - 3)w_p + (m - 2)(m - 3)w_s + ((m - 2)(m - 1) - 3n^2)w_m + (m - 2)w_q]$$

$$c_5 = 3 [n^2 - (m - 1)^2] + \dots$$

$$4 [3n^2 w_m^2 - (m - 1)^2 w_m w_p - (m - 1)^2 w_m w_s - (m - 1)(m - 2) w_p w_s - (m - 1) w_m w_q]$$

$$c_4 = 4 [m^2 w_p + m^2 w_s + (m^2 - 3n^2) w_m] + 8 [-n^2 w_m^3 + m^2 w_m w_p w_s]$$

$$c_3 = 3 [n^2 - (m + 1)^2] + \dots$$

$$4 [3n^2 w_m^2 - (m + 1)^2 w_m w_p - (m + 1)^2 w_m w_s - (m + 1)(m + 2) w_p w_s + (m + 1) w_m w_q]$$

$$c_2 = 2 [(m + 2)(m + 3)w_p + (m + 2)(m + 3)w_s + ((m + 2)(m + 1) - 3n^2)w_m - (m + 2)w_q]$$

$$c_1 = n^2 - (m + 3)^2$$

$$\alpha_{m-3} = -\frac{\sum_{\mu=1}^6 c_\mu \alpha_{m+4-\mu}}{c_7}$$

end for

Normalisation:

$$s_n = -\frac{\alpha_0}{2} + \sum_{m=1}^n \alpha_m$$

$$a_0 = (-1)^p \frac{\alpha_0}{2s_n}$$

for $m = 1$ **to** n **do**

$$a_m = (-1)^p \frac{\alpha_m}{s_n}$$

end for

The Chebyshev polynomial expansion coefficients of the example shown by Vlček and Unbehauen [97, Table VI] are:

```
a_3_6 = [ 0.0985975441, 0.0979370695, -0.0986423865, -0.1934009697, ...
           -0.0935059158, 0.0955182760, 0.1823184146, 0.0857438837, ...
           -0.0887676563, -1.0857982595 ];
```

Addendum

Working for Equation L.19 Re-writing Equation L.18:

$$\begin{aligned}
 w &= \frac{\operatorname{sn}^2(u, \kappa) \operatorname{cn}^2(u_0, \kappa) + \operatorname{cn}^2(u, \kappa) \operatorname{sn}^2(u_0, \kappa)}{(1 - \operatorname{sn}^2(u_0, \kappa)) \operatorname{sn}^2(u, \kappa) - (1 - \operatorname{sn}^2(u, \kappa)) \operatorname{sn}^2(u_0, \kappa)} \\
 &= \frac{\operatorname{sn}^2(u, \kappa) \operatorname{cn}^2(u_0, \kappa) + \operatorname{cn}^2(u, \kappa) \operatorname{sn}^2(u_0, \kappa)}{\operatorname{cn}^2(u_0, \kappa) \operatorname{sn}^2(u, \kappa) - \operatorname{cn}^2(u, \kappa) \operatorname{sn}^2(u_0, \kappa)} \\
 &= \frac{\operatorname{sc}^2(u, \kappa) + \operatorname{sc}^2(u_0, \kappa)}{\operatorname{sc}^2(u, \kappa) - \operatorname{sc}^2(u_0, \kappa)}
 \end{aligned} \tag{L.27}$$

Rearranging:

$$\begin{aligned}
 -(1 - w) \operatorname{sc}^2(u, \kappa) &= (1 + w) \operatorname{sc}^2(u_0, \kappa) \\
 \operatorname{sc}(u, \kappa) &= \pm i \operatorname{sc}(u_0, \kappa) \sqrt{\frac{1+w}{1-w}}
 \end{aligned}$$

Using the *Jacobi imaginary transformation* [36, Table 22.6.1], $\operatorname{sn}(iu, \kappa') = i \operatorname{sc}(u, \kappa)$, and selecting the “positive” value:

$$u = i \operatorname{arcsn} \left(\operatorname{sc}(u_0, \kappa) \sqrt{\frac{1+w}{1-w}}, \sqrt{1-\kappa'^2} \right)$$

The $\operatorname{sc}(u, \kappa)$ function has a zero at $u = 0$, a pole at $u = K$, period $2K + i4K'$, $\operatorname{sc}(iK', \kappa) = i$ and $\operatorname{sc}(K + iK', \kappa) = i\kappa'^{-1}$ [36, Tables 22.4.1, 22.4.2 and 22.5.1].

Substituting $\varphi_s = \frac{\omega_s T}{2}$, $\varphi_p = \frac{\pi - \omega_p T}{2}$ [96, Page 726] and $\sin \varphi_s = \operatorname{sn}(u_0, \kappa)$ [96, Equation 82] into Equation L.27 and recalling that $w_p = \cos \omega_p T$, at $u = K + iK'$:

$$w_p = \frac{-\frac{1}{\kappa'^2} + \tan^2 \varphi_s}{-\frac{1}{\kappa'^2} - \tan^2 \varphi_s}$$

Rearranging:

$$\begin{aligned}
 \kappa'^2 &= \cot^2 \varphi_s \frac{1 - w_p}{1 + w_p} \\
 &= \cot^2 \varphi_s \tan^2 \frac{\omega_p T}{2} \\
 &= \cot^2 \varphi_s \cot^2 \varphi_p
 \end{aligned}$$

That is, the complementary elliptic modulus, $\kappa' = \cot \varphi_s \cot \varphi_p$.

Working for linearising Equation 7 [96] Rearrange Equation 7 as:

$$\frac{df}{dw} = g \sqrt{1 - f^2}$$

where:

$$g(w) = \frac{n(w - w_m)}{\sqrt{(1 - w^2)(w - w_p)(w - w_s)}}$$

Differentiating both sides:

$$\frac{d^2f}{dw^2} = \frac{dg}{dw} \sqrt{1 - f^2} - g \frac{1}{2} \frac{1}{\sqrt{1 - f^2}} 2f \frac{df}{dw}$$

Substituting $\frac{df}{dw}$:

$$\frac{d^2f}{dw^2} = \frac{1}{g} \frac{dg}{dw} \frac{df}{dw} - g^2 f$$

If $w_q = \frac{w_p + w_s}{2}$:

$$\frac{1}{g} \frac{dg}{dw} = \frac{1}{w - w_m} + \frac{w}{1 - w^2} - \frac{w - w_q}{(w - w_p)(w - w_s)}$$

Rearranging:

$$\begin{aligned} & [(1-w^2)(w-w_m)(w-w_p)(w-w_s)] \frac{d^2f}{dw^2} \dots \\ & - [(1-w^2)(w-w_p)(w-w_s) + w(w-w_m)(w-w_p)(w-w_s) - (1-w^2)(w-w_m)(w-w_q)] \frac{df}{dw} \dots \\ & + n^2(w-w_m)^3 f = 0 \end{aligned}$$

Working for Equation 73 [96] The Chebyshev polynomial of the first kind satisfies the differential equation:

$$(1-x^2) \frac{d^2T_n(x)}{dx^2} - x \frac{dT_n(x)}{dx} + n^2 T_n(x) = 0 \quad (\text{L.28})$$

Equation L.25 is deliberately written in a form that can be solved with an expansion of $Z_{p,q}(w)$ in Chebyshev polynomials of the first kind, $T_m(w)$:

$$f(w) = \sum_{m=0}^n a_m T_m(w)$$

so that:

$$(1-w^2) \frac{d^2f}{dw^2} - w \frac{df}{dw} = - \sum_{m=0}^n m^2 a_m T_m(w)$$

Working for Equation 74 [96] Equation 74 uses the following properties of the Chebyshev polynomials:

$$\begin{aligned} \frac{dT_m(w)}{dw} &= m U_{m-1}(w) \\ (1-w^2) U_{m-1}(w) &= w T_m(w) - T_{m+1}(w) \\ T_{m-1}(w) - w T_m(w) &= w T_m(w) - T_{m+1}(w) \end{aligned}$$

so that:

$$(1-w^2) \frac{df}{dw} = \sum_{m=0}^n m a_m [T_{m-1}(w) - w T_m(w)]$$

Working for Equation 75 [96] Equation 75 results directly from substituting Equations 72, 73 and 74 into Equation 63 (shown above as Equation L.25):

$$-\sum_{m=0}^n m^2 a_m g_2(w) T_m(w) - \sum_{m=0}^n m a_m g_1(w) [T_{m-1}(w) - w T_m(w)] + \sum_{m=0}^n a_m n^2 g_0(w) T_m(w) = 0$$

Working for Table V [96] Expanding $g_0(w)$, $g_1(w)$ and $g_2(w)$ in Equation 75 and setting $w_q = \frac{w_p+w_s}{2}$:

$$\begin{aligned} & - \sum_{m=0}^n m^2 \alpha_m [(w-w_p)(w-w_s)(w-w_m)] T_m(w) \dots \\ & - \sum_{m=0}^n m \alpha_m [(w-w_p)(w-w_s) - (w-w_m)(w-w_q)] [T_{m-1}(w) - w T_m(w)] \dots \\ & + \sum_{m=0}^n \alpha_m \left[n^2 (w-w_m)^3 \right] T_m(w) = 0 \\ & - \sum_{m=0}^n m^2 \alpha_m [w^3 - w_p w^2 - w_s w^2 - w_m w^2 + w_m w_p w + w_m w_s w + w_p w_s w - w_p w_m w_s] T_m(w) \dots \\ & - \sum_{m=0}^n m \alpha_m [w^2 - w_p w - w_s w + w_p w_s - w^2 + w_m w + w_q w - w_q w_m] [T_{m-1}(w) - w T_m(w)] \dots \end{aligned}$$

$$+ \sum_{m=0}^n n^2 \alpha_m [w^3 - 3w_m w^2 + 3w_m^2 w - w_m^3] T_m(w) = 0$$

After much algebra (shown in the Octave script `zolotarev_vlcek_unbehauen_table_v_test.m`) I arrived at:

$$\begin{aligned}
& \sum_{m=3}^{n+3} \left[n^2 - (m-3)^2 \right] \alpha_{m-3} T_m(w) \quad \dots \\
& + \sum_{m=2}^{n+2} 2 [(m-2)(m-3)w_p + (m-2)(m-3)w_s \quad \dots \\
& \quad + ((m-2)(m-1) - 3n^2)w_m + (m-2)w_q] \alpha_{m-2} T_m(w) \quad \dots \\
& + \sum_{m=1}^{n+1} 3 \left[n^2 - (m-1)^2 \right] + \quad \dots \\
& \quad 4 \left[3n^2 w_m^2 - (m-1)^2 w_m w_p - (m-1)^2 w_m w_s - (m-1)(m-2) w_p w_s - (m-1) w_m w_q \right] \alpha_{m-1} T_m(w) \quad \dots \\
& + \sum_{m=0}^n 4 [m^2 w_p + m^2 w_s + (m^2 - 3n^2) w_m] + 8 [-n^2 w_m^3 + m^2 w_m w_p w_s] \alpha_m T_m(w) \quad \dots \\
& + \sum_{m=-1}^{n-1} 3 \left[n^2 - (m+1)^2 \right] + \quad \dots \\
& \quad 4 \left[3n^2 w_m^2 - (m+1)^2 w_m w_p - (m+1)^2 w_m w_s - (m+1)(m+2) w_p w_s + (m+1) w_m w_q \right] \alpha_{m+1} T_m(w) \quad \dots \\
& + \sum_{m=-2}^{n-2} 2 [(m+2)(m+3)w_p + (m+2)(m+3)w_s + ((m+2)(m+1) - 3n^2)w_m - (m+2)w_q] \alpha_{m+2} T_m(w) \quad \dots \\
& + \sum_{m=-3}^{n-3} \left[n^2 - (m+3)^2 \right] \alpha_{m+3} T_m(w) = 0
\end{aligned}$$

Algorithm L.5 follows by collecting terms in the Chebyshev polynomials of equal order. The recursion is initialised by setting $\alpha_n = 1$. At each backwards recursion, $m = n+2, \dots, 3$, the next coefficient calculated is α_{m-3} .

L.7.2 Narrow-band FIR filter design with the Zolotarev polynomials

Degree equations for the Zolotarev polynomials

If the Zolotarev polynomial is scaled to lie in the range $[0, 1]$ and the stop-band specification is $a_{s_{dB}} = 20 \log_{10} a_s < 0$:

$$\frac{2}{1 + f_m} \leq 10^{a_{s_{dB}}/20} \quad (\text{L.29})$$

Rearranging:

$$f_m \geq y_m = 2 \times 10^{-a_{s_{dB}}/20} - 1 \quad (\text{L.30})$$

Recalling Equation L.23, the scaled maximum value is:

$$\cosh \left[n \log \frac{\Theta(\sigma_m + u_0, \kappa)}{\Theta(\sigma_m - u_0, \kappa)} \right] \geq y_m \quad (\text{L.31})$$

and the stop-band degree equation is:

$$n \geq \frac{\operatorname{arccosh} y_m}{\log \frac{\Theta(\sigma_m + u_0, \kappa)}{\Theta(\sigma_m - u_0, \kappa)}} \quad (\text{L.32})$$

Alternatively, solving for y_m with $\lambda = e^x$:

$$\frac{1}{2} [\lambda + \lambda^{-1}] \geq y_m \quad (\text{L.33})$$

$$\lambda^2 - 2y_m \lambda + 1 \geq 0 \quad (\text{L.34})$$

The stop-band degree equation becomes [96, Equation 85]:

$$n \geq \frac{\log \left(y_m + \sqrt{y_m^2 - 1} \right)}{\log \frac{\Theta(\sigma_m + u_0, \kappa)}{\Theta(\sigma_m - u_0, \kappa)}} \quad (\text{L.35})$$

Zahradník et al. [119] derive a degree equation for narrow band-pass Zolotarev polynomial FIR filters in terms of the pass-band attenuation specification, $a_{p_{dB}} = 20 \log_{10} a_p < 0$ and the pass-band bandwidth, $\Delta_p T = \omega_{p2} T - \omega_{p1} T$. Their procedure selects the elliptic function modulus, κ , by setting [119, Equation 13]:

$$\frac{\Theta(\sigma_{p1} + u_0, \kappa)}{\Theta(\sigma_{p1} - u_0, \kappa)} = \frac{\Theta(\sigma_{p2} + u_0, \kappa)}{\Theta(\sigma_{p2} - u_0, \kappa)}$$

The response is scaled so that the pass-band degree equation is [119, Equation 14](with corrections^f):

$$n \geq \frac{\operatorname{arccosh} \left(2 \times 10^{(a_{p_{dB}} - a_{s_{dB}})/20} - 1 \right)}{\log \frac{\Theta(\sigma_{p1} + u_0, \kappa)}{\Theta(\sigma_{p1} - u_0, \kappa)}} \quad (\text{L.35})$$

Unfortunately, the pass-band bandwidth relationship usually does not hold after the elliptic function quarter-period, $K(\kappa)$, is translated to integral values of n , p and q ,

The Zolotarev polynomial FIR filter design procedure of Vlček and Unbehauen

Vlček and Unbehauen [96, Section VII] give the following procedure for the design of narrow-band FIR filters based on the Zolotarev polynomials with specified stop-band bandwidth and stop-band attenuation:

1. Specify the desired pass-band and stop-band edges at angular frequencies $\omega_p T < \omega_s T$, and the stop-band attenuation, $a_{s_{dB}} = 20 \log_{10} a_s < 0$
2. Evaluate the elliptic function modulus, κ , for $\varphi_p = \frac{\pi - \omega_p T}{2}$ and $\varphi_s = \frac{\omega_s T}{2}$, $\kappa' = \cot \varphi_p \cot \varphi_s$

^fZahradník et al. use the Jacobi Eta function, the ratio of Jacobi Eta functions is claimed to be real at w_{p1} and log is missing.

3. Use the degree equation, Equation L.35, to find the degree, n , that satisfies the attenuation requirement

$$f_m > y_m = 2 \times 10^{-a_{s_{dB}}/20} - 1$$

corresponding to the maximum of the scaled Zolotarev polynomial.

4. Determine integer values of p and q corresponding to:

$$\frac{q}{n} K(\kappa) = F(\varphi_p, \kappa), \quad \frac{p}{n} K(\kappa) = F(\varphi_s, \kappa)$$

5. Calculate the resulting values of w_p , w_s and w_m :

$$\begin{aligned} u_0 &= \frac{p}{n} K(\kappa), \quad u_q = \frac{q}{n} K(\kappa) \\ w_p &= \cos \omega_p T = 2 \operatorname{sn}^2(u_q, \kappa) - 1 \\ w_s &= \cos \omega_s T = 1 - 2 \operatorname{sn}^2(u_0, \kappa) \\ w_m &= \cos \omega_m T = w_s + 2 \frac{\operatorname{sn}(u_0, \kappa) \operatorname{cn}(u_0, \kappa)}{\operatorname{dn}(u_0, \kappa)} Z(u_0, \kappa) \\ u_m &= \sigma_m + iK' \\ f_m &= Z_{p,q}(u_m, \kappa) \end{aligned}$$

6. Perform Algorithm L.5 to find the Chebyshev polynomial coefficients, a_m , and convert these to the impulse response [96, Equation 87]: $a_0 = h_M$ and $a_m = 2h_{M-m}$.

The Octave script `zolotarev_vlcek_unbehauen_test.m` designs an FIR filter that approximates that shown in Figure 4 of Vlček and Unbehauen [96]. The initial specification is $fp = 0.1$, $fs = 0.15$ and $a_{s_{dB}} = -20\text{dB}$. The final filter has:

```
p=6 % Zeros in lower stop-band
q=17 % Zeros in upper stop-band
N=46 % Degree of FIR polynomial
k=0.770292 % Elliptic modulus
fp=0.105432 % Lower stop-band edge
fmax=0.131418 % Pass-band centre frequency
fs=0.157429 % Upper stop-band edge
delta=-21.224034 % Stop-band attenuation (dB)
```

The z -domain impulse reponse coefficients of the FIR filter are:

```
h_6_17 = [ 0.0295797662, 0.0123578798, 0.0011255068, -0.0142207618, ...

Figure L.37 shows the normalised Zolotarev polynomial of the FIR filter. Figure L.38 shows the frequency response of the FIR filter. Figure L.39 shows the zeros of the FIR filter. Note that these are all *double* zeros.

The Octave script `zolotarev_zahradnik_degree_test.m` attempts to reproduce the examples given by Zahradník et al. [119]. Figure L.40 shows the normalised Zolotarev polynomial, $Z_{100,37}(w, 0.4)$, calculated with Equation 7 of Zahradník et al. The Octave script `zolotarev_zahradnik_degree_test.m` checks the inverse transformation of w to u shown in Equation L.19. Both the arcsc and arccn Octave functions accurately invert w to u over the range of the pass-band in Example 1 of Zahradník et al.. A 3rd-order polynomial fit over that range is accurate to 4 decimal places. I failed to reproduce the results of Zahradník et al. for their Example 1 with a pass-band constraint. Figure L.41 shows a filter designed with the stop-band bandwidth and attenuation of Zahradník et al.'s Example 2. Figure L.42 shows the main lobe of the response.

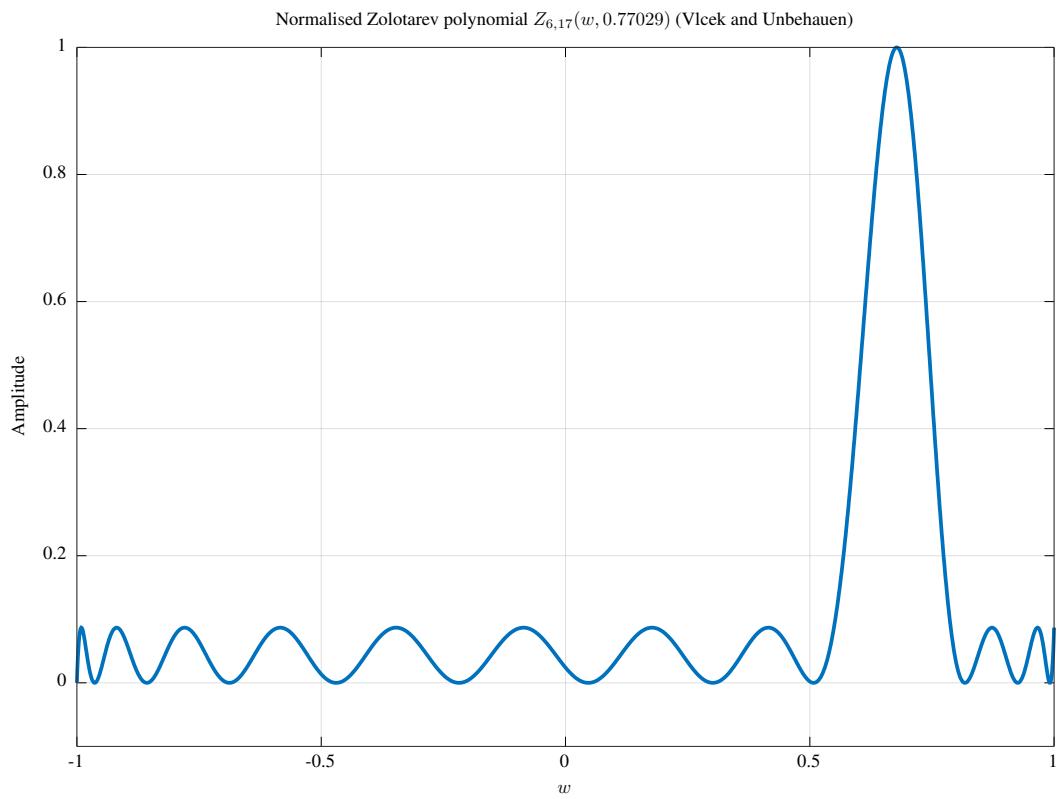

Figure L.37: Normalised Zolotarev polynomial approximating that of Figure 4 in Vlček and Unbehauen [96]

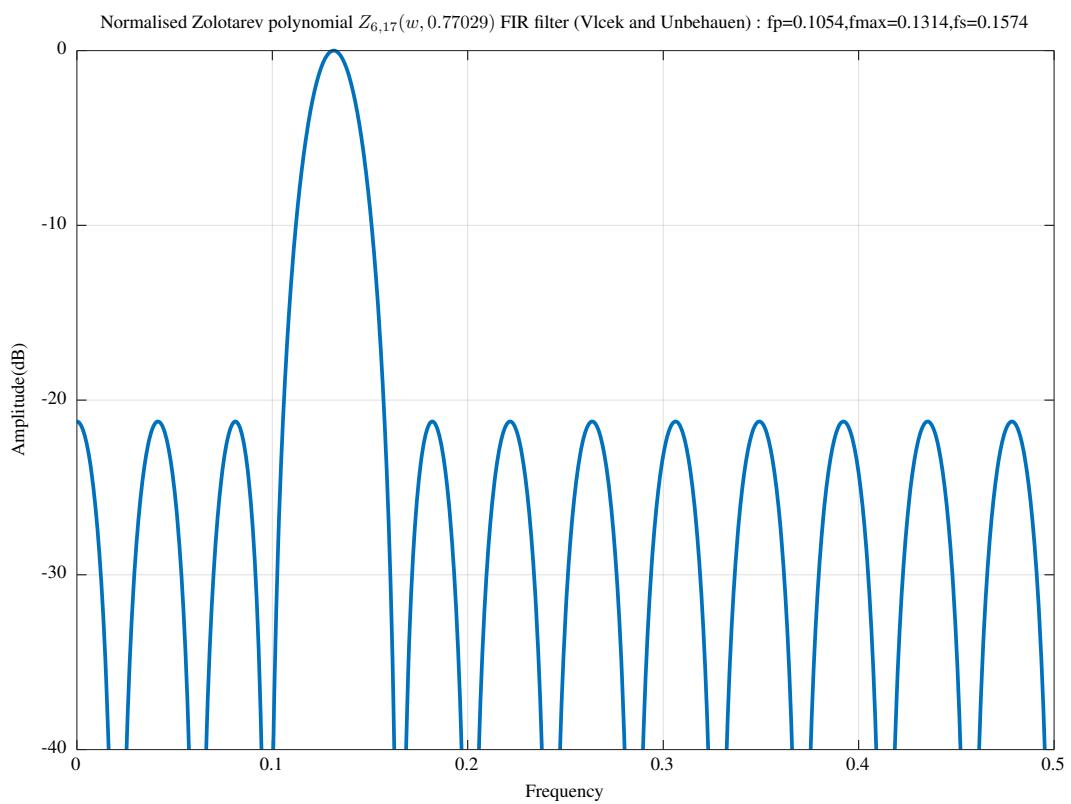

Figure L.38: FIR filter response approximating that of Figure 4 in Vlček and Unbehauen [96]

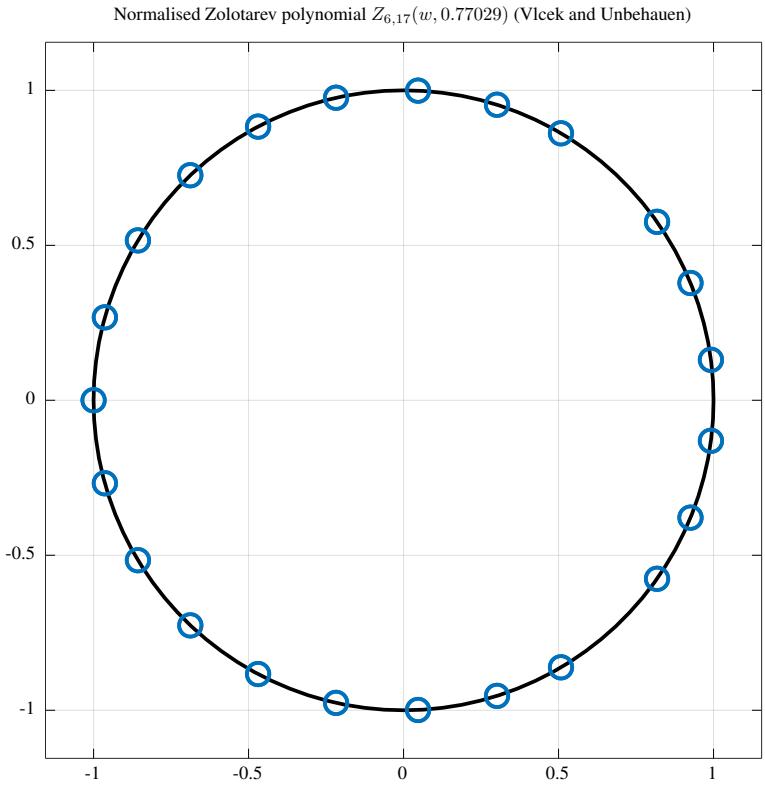

Figure L.39: Zeros of an FIR filter approximating that of Figure 4 in Vlček and Unbehauen [96]

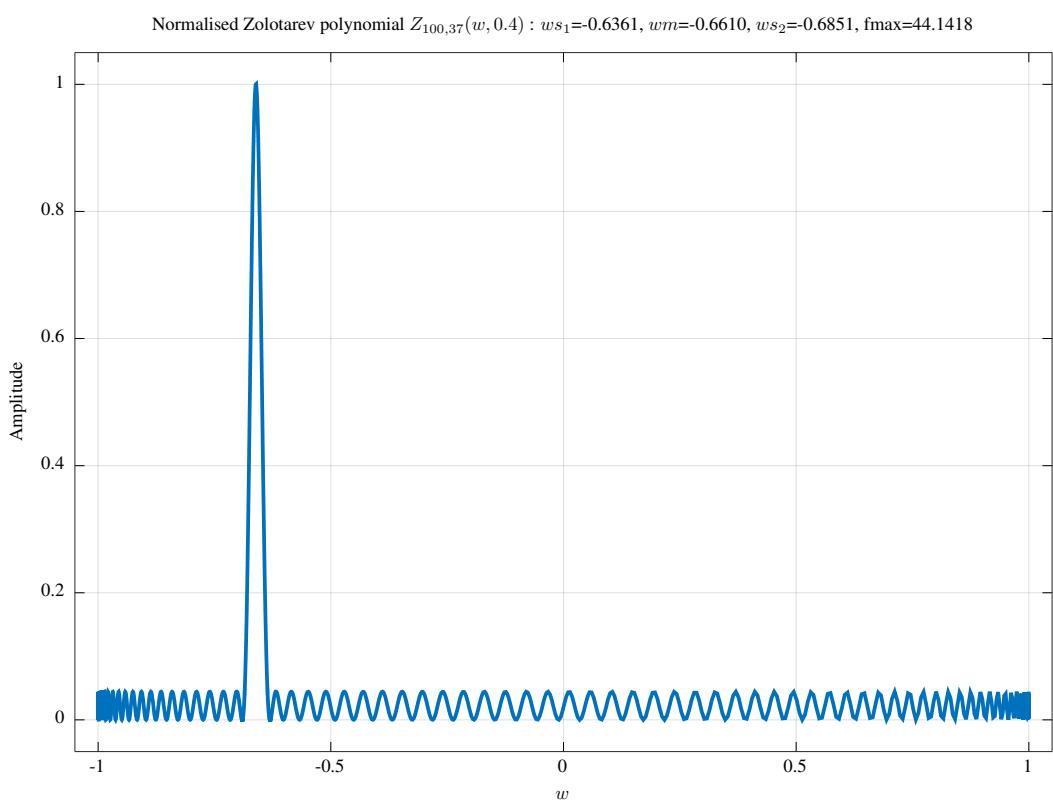

Figure L.40: Normalised Zolotarev polynomial $Z_{100,37}(w, 0.4)$ calculated with Equation 7 of Zahradník et al. [99]

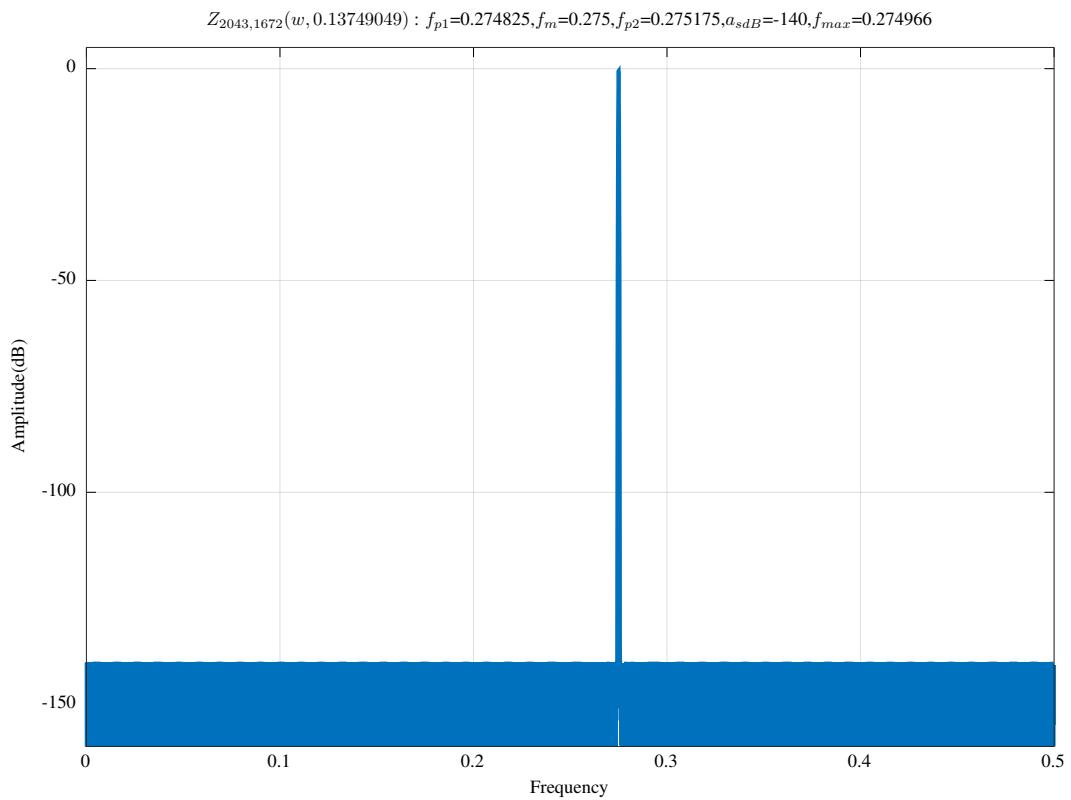

Figure L.41: Normalized Zolotarev polynomial FIR filter approximating Example 2 of Zahradník *et al.* [99] with stop-band constraints.

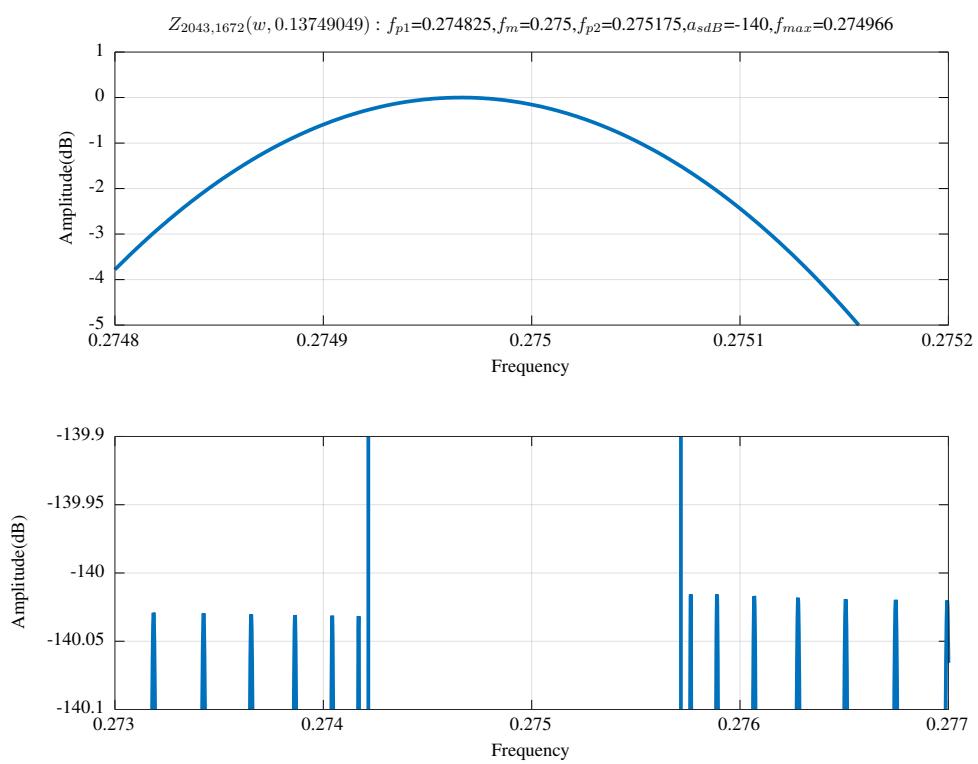

Figure L.42: Main lobe of the response of a normalized Zolotarev polynomial FIR filter approximating Example 2 of Zahradník *et al.* [99] with stop-band constraints.

The Zolotarev polynomial FIR filter cascade structure design procedure of Zahradník et al.

It is often convenient to express an FIR filter polynomial as the cascade product of sub-filters [155, 29, 76, 77, 172]. As I show in the [Introduction](#), it may be difficult to accurately determine the roots of the FIR filter polynomial and so determine the sub-filters. For example, see [Smith](#) [76]. Zahradník, Šusta et al. [120] derive an expression for the double-roots of the normalised Zolotarev polynomial:

$$Q_{p,q}(w, \kappa) = \frac{1 + Z_{p,q}(w, \kappa)}{1 + Z_{p,q}(w_{max}, \kappa)}$$

where w_{max} is the centre-frequency of the main lobe. Their Figure 2 shows that $Q_{p,q}(w, \kappa)$ has $\lfloor \frac{p}{2} \rfloor$ double zeros to the right of the maximum ($u \in [K + iK', K]$ and $w \in [w_p, 1]$), $\lfloor \frac{q}{2} \rfloor$ double zeros to the left of the maximum, ($u \in [0, iK']$ or $w \in [-1, w_s]$), for a total of $\frac{p+q-2}{2}$ double zeros as well as:

- zeros at $w = \pm 1$ if p is odd and q is odd
- one zero at $w = 1$ if p is odd and q is even
- one zero at $w = -1$ if p is even and q is odd
- no other zeros if p is even and q is even

Recall Equation L.20:

$$\begin{aligned} Z_{p,q}(u, \kappa) &= (-1)^p T_{p+q}(\cos \Phi(u, \kappa)) \\ \cos \Phi(u, \kappa) &= \frac{1}{2} \left[\frac{H(u + u_0, \kappa)}{H(u - u_0, \kappa)} + \frac{H(u - u_0, \kappa)}{H(u + u_0, \kappa)} \right] \end{aligned}$$

On the “vertical” sections of the path of u corresponding to the locations of the zeros of $Q(w, \kappa)$, substituting $u - u_0$ into Equation L.21:

$$H(u - u_0, \kappa) = \begin{cases} -H^\dagger(u + u_0, \kappa) & u \in [0, iK'] \\ H^\dagger(u + u_0, \kappa) & u \in [K + iK', K] \end{cases} \quad (\text{L.36})$$

where H^\dagger is the complex-conjugate of H . The $\Phi(u, \kappa)$ function of Equation L.20 becomes:

$$\Phi(u, \kappa) = \begin{cases} -2 \arg H(u + u_0, \kappa) + \pi & u \in [0, iK'] \\ 2 \arg H(u + u_0, \kappa) & u \in [K + iK', K] \end{cases}$$

The double-zero locations can be found by interpolation of the multiples of $\frac{\pi}{n}$ into $2 \arg H(u + u_0, \kappa)$. Figure L.43 shows the locations of the double zeros of $Q_{p,q}(w, 0.75)$ for pairs of odd and even p and q [120, Figure 2]. Figure L.44 shows the locations of the double zeros of $Q_{p,q}(w, 0.75)$ for pairs of odd and even p and q superimposed on $2 \arg H(u + u_0, 0.75)$, normalised to $\frac{n}{\pi}$, in the regions on either side of the central lobe.

Zahradník, Šusta et al. [120, Table I] show an algorithm, reproduced below as Algorithm L.6, for the calculation of the coefficients of the expansion in Chebyshev polynomials of the first kind of the product of the factors, $(w - w_l)$, of a polynomial. They recommend ordering the roots in ascending order of z -domain angular frequency and the m subfilters select the roots with the ordering $\rho(l)$, $l = 1, \dots, m$ [120, Equation 8]:

$$\rho(l) = \begin{cases} \frac{m+l}{2} & m \text{ and } l \text{ both odd or both even} \\ \frac{m-l+1}{2} & \text{otherwise} \end{cases}$$

In addition, they recommend normalising each sub-filter to the value at the frequency of the central lobe maximum of the overall filter [120, Equation 14].

The Octave script `zolotarevFIRcascade_test.m` attempts to reproduce Zahradník, Šusta et al.’s Examples 1 and 2. As mentioned previously, I do not understand their method of calculating the degree of the filter from the required pass-band bandwidth. Figure L.45 reproduces Figure 4 of Zahradník, Šusta et al., illustrating their Example 1. Sub-filters 1 and 2 are identical, as expected after examining Zahradník, Šusta et al.’s Figure 3. However, the sub-filter 1 and sub-filter 2 shown in their Figure 4 appear to have a similar shape but a different gain, the filter impulse responses shown in their Table II are all different and I do not understand how their Equation 15 corresponds to the numbering shown in their Figure 3. I tried randomly rearranging the roots with the Octave `randperm` function. The range of the responses of the resulting sub-filters was far greater.

Figure L.46 shows the double-zero locations near ± 1 and the central lobe of $Q_{2159,540}(w, 0.16238959)$ for Zahradník, Šusta et al.’s Example 2 [120]. Figure L.47 attempts to reproduce Zahradník, Šusta et al.’s Figure 5 showing $Q_{2159,540}(w, 0.16238959)$ with 3 subfilters. Algorithm L.6, the calculation of the coefficients of the Chebyshev polynomials of the first kind, is implemented with the `MPFR` [1] library in the Octave `octfile roots2T.cc`.

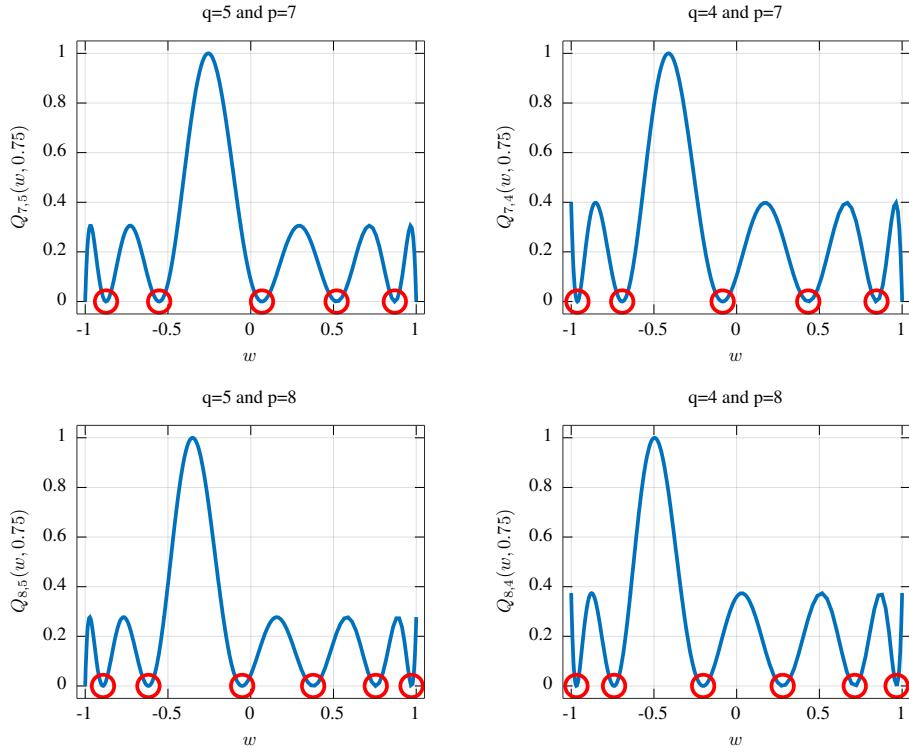

Figure L.43: Double-zero locations of $Q_{p,q}(w, 0.75)$ [120, Figure 2]

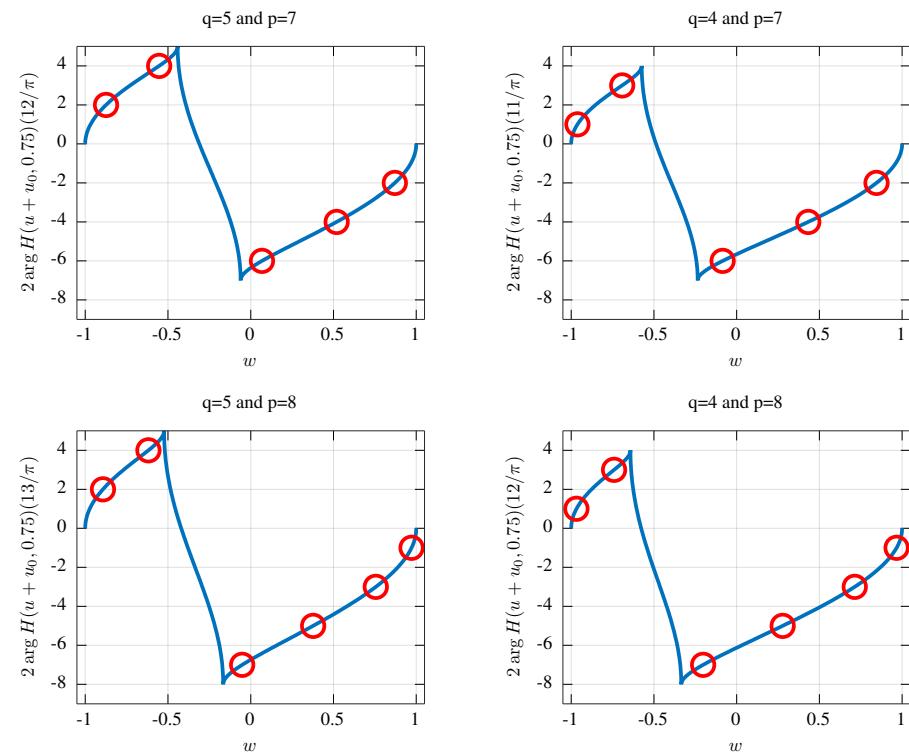

Figure L.44: Double-zero locations of $Q_{p,q}(w, 0.75)$ superimposed on $2 \arg H(u + u_0, 0.75)$ normalised to $\frac{n}{\pi}$

Algorithm L.6 Recursion of Zahradník, Šusta et al. for the calculation of the scaled coefficients of the expansion, in Chebyshev polynomials of the first kind, of the product of the n factors, $(w - w_m)$, of a polynomial [120, Table I]

Require: w_0, \dots, w_{n-1}

Initialisation:

$$\alpha_0^{(0)} = -w_0, \alpha_1^{(0)} = 1$$

Body:

for $m = 1$ **to** $n - 1$ **do**

$$\alpha_{m+1}^{(m-1)} = 0$$

$$\alpha_0^{(m)} = \alpha_1^{(m-1)} - 2w_m\alpha_0^{(m-1)}$$

$$\alpha_1^{(m)} = \alpha_2^{(m-1)} + 2\alpha_0^{(m-1)} - 2w_m\alpha_1^{(m-1)}$$

for $l = 2$ **to** m **do**

$$\alpha_l^{(m)} = \alpha_{l-1}^{(m-1)} + \alpha_{l+1}^{(m-1)} - 2w_m\alpha_l^{(m-1)}$$

end for

$$\alpha_{m+1}^{(m)} = 1$$

end for

Output:

$$a_k = \alpha_k^{(n)} \quad k = 0, \dots, n$$

.

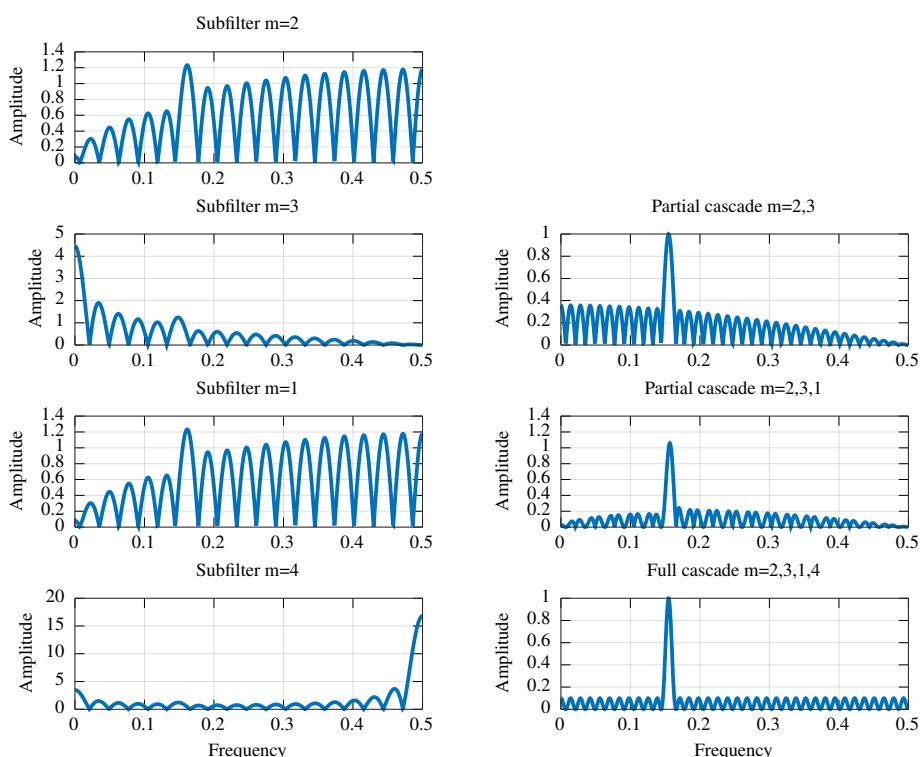

Figure L.45: Amplitude responses of the 4 sub-filters and the partial cascades of the sub-filters of a normalised Zolotarev band-pass filter with zero-phase response $Q_{22,49}(w, 0.46850107)$ [120, Figure 4]

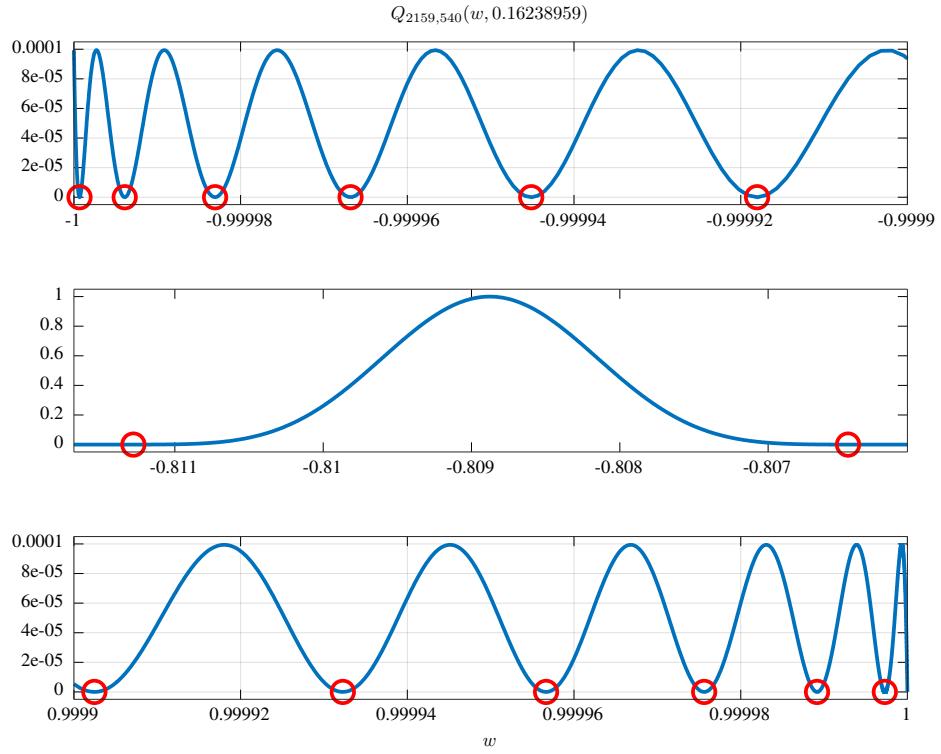

Figure L.46: Detailed view of the double-zero locations of $Q_{2159,540}(w, 0.16238959)$ near ± 1 and the central lobe for Zahradník, Šusta et al.'s Example 2 [120]

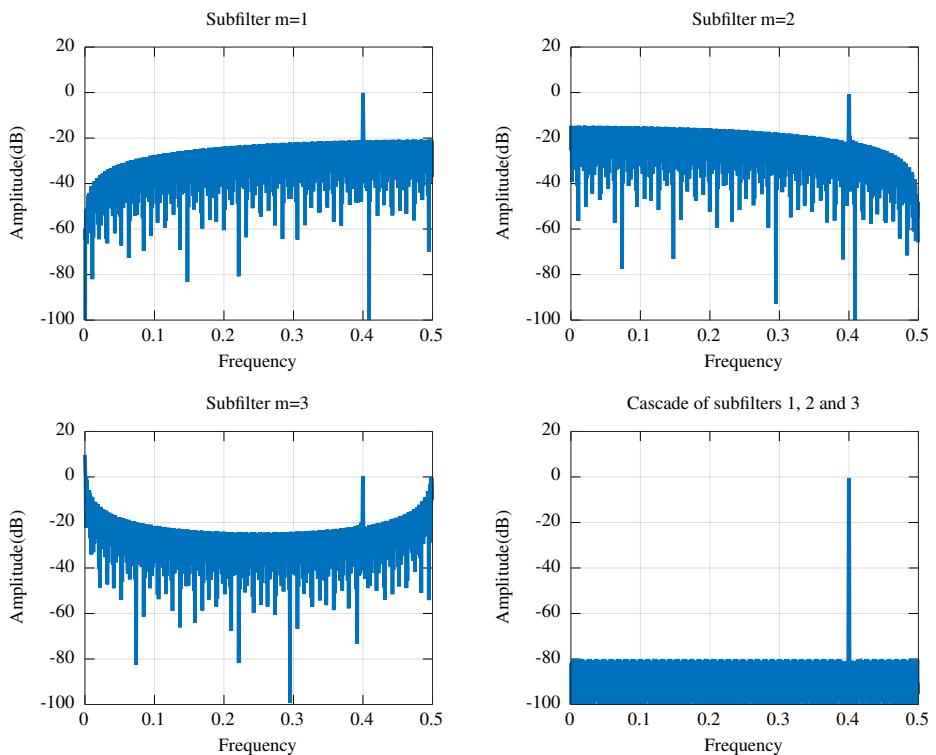

Figure L.47: Amplitude responses of the 3 sub-filters cascade of the sub-filters of a normalised Zolotarev band-pass filter with zero-phase response $Q_{2159,540}(w, 0.16238959)$ [120, Figure 5]

Addendum

Working for Equation L.36 Substituting $u = -u_0 + iyK'$, where $y \in [0, 1]$, into Equation L.21:

$$\begin{aligned} H^\dagger(-u_0 + iyK', \kappa) &= iq^{-\frac{1}{4}} e^{\frac{i\pi(u_0+iyK')}{2K}} \Theta(-u_0 - iyK' - iK', \kappa) \\ &= -H(u_0 + iyK', \kappa) \end{aligned}$$

Substituting $u = K - u_0 + iyK'$, where $y \in [0, 1]$, into Equation L.21:

$$\begin{aligned} H^\dagger(K - u_0 + iyK', \kappa) &= iq^{-\frac{1}{4}} e^{\frac{i\pi(-K+u_0+iyK')}{2K}} \Theta(K - u_0 - iyK' - iK', \kappa) \\ &= -iq^{-\frac{1}{4}} e^{\frac{i\pi(K+u_0+iyK')}{2K}} \Theta(-K - u_0 - iyK' - iK', \kappa) \\ &= H(K + u_0 + iyK', \kappa) \end{aligned}$$

Working for Algorithm L.6 This is an application of the recurrence relations of the Chebyshev polynomials of the first kind:

$$\begin{aligned} T_0(w) &= 1 \\ T_1(w) &= w \\ T_{n+1}(w) &= 2wT_n(w) - T_{n-1}(w) \end{aligned}$$

For the first zero (dropping the argument, w , of T_0 etc.):

$$(w - w_0) = \alpha_1^{(0)} T_1 + \alpha_0^{(0)} T_0$$

so that $\alpha_1^{(0)} = 1$ and $\alpha_0^{(0)} = -w_0$. Multiplying by the second zero:

$$\begin{aligned} (w - w_1) \left[\alpha_1^{(0)} T_1 + \alpha_0^{(0)} T_0 \right] &= \frac{\alpha_1^{(0)}}{2} (2wT_1 - T_0) + \frac{\alpha_1^{(0)}}{2} T_0 + \alpha_0^{(0)} wT_0 - w_1 \alpha_1^{(0)} T_1 - w_1 \alpha_0^{(0)} T_0 \\ &= \alpha_1^{(0)} \frac{T_2}{2} + \left(2\alpha_0^{(0)} - 2w_1 \alpha_1^{(0)} \right) \frac{T_1}{2} + \left(\alpha_1^{(0)} - 2w_1 \alpha_0^{(0)} \right) \frac{T_0}{2} \end{aligned}$$

so that $\alpha_2^{(1)} = 1$, $\alpha_1^{(1)} = 2\alpha_0^{(0)} - 2w_1 \alpha_1^{(0)}$ and $\alpha_0^{(1)} = \alpha_1^{(0)} - 2w_1 \alpha_0^{(0)}$. For the third zero, ignoring the scaling by 2:

$$\begin{aligned} (w - w_2) \left[\alpha_2^{(1)} T_2 + \alpha_1^{(1)} T_1 + \alpha_0^{(1)} T_0 \right] &= \frac{\alpha_2^{(1)}}{2} (2wT_2 - T_1) + \frac{\alpha_2^{(1)}}{2} T_1 + \frac{\alpha_1^{(1)}}{2} (2wT_1 - T_0) + \frac{\alpha_1^{(1)}}{2} T_0 + \alpha_0^{(1)} wT_0 \quad \dots \\ &\quad - w_2 \alpha_2^{(1)} T_2 - w_2 \alpha_1^{(1)} T_1 - w_2 \alpha_0^{(1)} T_0 \\ &= \alpha_2^{(1)} \frac{T_3}{2} + \left(\alpha_1^{(1)} - 2w_2 \alpha_2^{(1)} \right) \frac{T_2}{2} \quad \dots \\ &\quad + \left(\alpha_2^{(1)} + 2\alpha_0^{(1)} - 2w_2 \alpha_1^{(1)} \right) \frac{T_1}{2} + \left(\alpha_1^{(1)} - 2w_2 \alpha_0^{(1)} \right) \frac{T_0}{2} \end{aligned}$$

In general, for $m = 1, 2, \dots$:

$$\begin{aligned} (w - w_m) \sum_{l=0}^m \alpha_l^{(m-1)} T_l &= \sum_{l=1}^m \frac{\alpha_l^{(m-1)}}{2} (2wT_l - T_{l-1}) + \sum_{l=1}^m \frac{\alpha_l^{(m-1)}}{2} T_{l-1} + \alpha_0^{(m-1)} wT_0 - \sum_{l=0}^m w_m \alpha_l^{(m-1)} T_l \\ &= \sum_{l=1}^m \alpha_l^{(m-1)} \frac{T_{l+1}}{2} + \sum_{l=1}^m \alpha_l^{(m-1)} \frac{T_{l-1}}{2} + 2\alpha_0^{(m-1)} \frac{T_1}{2} - \sum_{l=0}^m 2w_m \alpha_l^{(m-1)} \frac{T_l}{2} \\ &= \sum_{l=2}^{m+1} \alpha_{l-1}^{(m-1)} \frac{T_l}{2} + \sum_{l=0}^{m-1} \alpha_{l+1}^{(m-1)} \frac{T_l}{2} + 2\alpha_0^{(m-1)} \frac{T_1}{2} - \sum_{l=0}^m 2w_m \alpha_l^{(m-1)} \frac{T_l}{2} \\ &= \alpha_m^{(m-1)} \frac{T_{m+1}}{2} + \alpha_{m-1}^{(m-1)} \frac{T_m}{2} + \sum_{l=2}^{m-1} \alpha_{l-1}^{(m-1)} \frac{T_l}{2} \quad \dots \\ &\quad + \sum_{l=2}^{m-1} \alpha_{l+1}^{(m-1)} \frac{T_l}{2} + \alpha_2^{(m-1)} \frac{T_1}{2} + \alpha_1^{(m-1)} \frac{T_0}{2} + 2\alpha_0^{(m-1)} \frac{T_1}{2} \quad \dots \end{aligned}$$

$$\begin{aligned}
& - 2w_m \alpha_m^{(m-1)} \frac{T_m}{2} - \sum_{l=2}^{m-1} 2w_m \alpha_l^{(m-1)} \frac{T_l}{2} - 2w_m \alpha_1^{(m-1)} \frac{T_1}{2} - 2w_m \alpha_0^{(m-1)} \frac{T_0}{2} \\
& = \alpha_m^{(m-1)} \frac{T_{m+1}}{2} + \left[\alpha_{m-1}^{(m-1)} - 2w_m \alpha_m^{(m-1)} \right] \frac{T_m}{2} \quad \dots \\
& \quad + \sum_{l=2}^{m-1} \left[\alpha_{l-1}^{(m-1)} + \alpha_{l+1}^{(m-1)} - 2w_m \alpha_l^{(m-1)} \right] \frac{T_l}{2} \quad \dots \\
& \quad + \left[\alpha_2^{(m-1)} + 2\alpha_0^{(m-1)} - 2w_m \alpha_1^{(m-1)} \right] \frac{T_1}{2} + \left[\alpha_1^{(m-1)} - 2w_m \alpha_0^{(m-1)} \right] \frac{T_0}{2}
\end{aligned}$$

L.7.3 Almost equi-ripple low-pass FIR filter design with the Zolotarev polynomials

Vlček and Zahradník [99, 100] describe the use of modified Zolotarev polynomials to design “almost equi-ripple” low-pass FIR filters. They assume a solution of the form $\sqrt{1 - w^2} S_{p,q}(w, \kappa)$ ^g and use $S_{p,q}(w, \kappa)$ as the generating polynomial of a low-pass FIR filter^h:

$$\begin{aligned} S_{p,q}(w, \kappa) &= \sum_{m=0}^n a_m^+ U_m(w) \\ \mathcal{S}(w) &= \int S_{p,q}(w, \kappa) dw \\ Q(w) &= \frac{\mathcal{S}(w) - \mathcal{N}_1}{\mathcal{N}_2 - \mathcal{N}_1} \end{aligned}$$

where $U_m(w)$ is the m ’th Chebyshev polynomial of the second kind, $Q(w)$ is the zero-phase transfer function of the FIR filter and the normalising constants \mathcal{N}_1 and \mathcal{N}_2 are:

$$\begin{aligned} \mathcal{N}_1 &= \begin{cases} \mathcal{S}(w = -1) & \text{for } q \text{ even} \\ \mathcal{S}\left(w = \cos \frac{n\pi}{n+1}\right) & \text{for } q \text{ odd} \end{cases} \\ \mathcal{N}_2 &= \begin{cases} \mathcal{S}(w = 1) & \text{for } p \text{ even} \\ \mathcal{S}\left(w = \cos \frac{\pi}{n+1}\right) & \text{for } p \text{ odd} \end{cases} \end{aligned}$$

The frequency response of a symmetric FIR filter of length $2n + 3$ is:

$$H(\omega) = \sum_{m=0}^{2n+2} h_m e^{-im\omega T}$$

where the impulse response, $h_m = h_{2n+2-m}$, $m = 0, \dots, n$. The zero-phase frequency response, $Q(\omega)$, is related to the frequency response, $H(\omega)$, by:

$$\begin{aligned} H(\omega) &= e^{-i(n+1)\omega T} \left[h_{n+1} + \sum_{m=0}^n h_m e^{-i[m-(n+1)]\omega T} + \sum_{m=n+2}^{2n+2} h_m e^{-i[m-(n+1)]\omega T} \right] \\ &= e^{-i(n+1)\omega T} \left[h_{n+1} + \sum_{m=0}^n h_m e^{-i[m-(n+1)]\omega T} + \sum_{m=0}^n h_{2n+2-m} e^{-i[2n+2-m-(n+1)]\omega T} \right] \\ &= e^{-i(n+1)\omega T} \left[h_{n+1} + \sum_{m=0}^n h_m e^{-i[m-(n+1)]\omega T} + \sum_{m=0}^n h_{2n+2-m} e^{i[m-(n+1)]\omega T} \right] \\ &= e^{-i(n+1)\omega T} \left[h_{n+1} + 2 \sum_{m=0}^n h_m \cos[(n+1)-m]\omega T \right] \\ &= e^{-i(n+1)\omega T} Q(\omega) \end{aligned}$$

Vlček and Zahradník [99, Tables 4 and 5] provide an algorithm for calculating the $2(p+q)+3$ coefficients of the impulse response of the FIR filter, reproduced here (with altered normalisation) as Algorithm L.7. I have combined Vlček and Zahradník’s Tables 4 and 5 because the normalisation step in Table 4 normalises the a^+ coefficients as if they are coefficients of $\frac{d}{dw} T_m(w)$ rather than $U_m(w)$.

^gSee Rilett [52], “If one uses $x = -\cos \theta$ for a frequency variable instead of ω , ... the problem of designing for equal-ripple performance reduces to finding even and odd polynomials $P_n(x)$ so that $P_n(x)/\sqrt{1-x^2}$ oscillates between ± 1 exactly $n+1$ times in a prescribed interval $-1 < -x_c \leq x \leq x_c < 1$ $P_n()$ is given then by $2P_n() = (1 + \sqrt{1-x_c^2}) T_n\left(\frac{x}{x_c}\right) - (1 - \sqrt{1-x_c^2}) T_{n-2}\left(\frac{x}{x_c}\right)$ ”

^hThe normalisation is shown in Vlček and Zahradník [99, 100] as:

$$Q(w) = -\mathcal{N}_1 + \frac{1}{\mathcal{N}_2 - \mathcal{N}_1} \mathcal{S}(w)$$

Algorithm L.7 Vlček and Zahradník's algorithm for the evaluation of the impulse response, $h(m)$, of an “almost equi-ripple” low-pass FIR filter [99, Tables 4 and 5]

Require: p, q and κ

Initialisation:

$$n = p + q$$

$$u_0 = \frac{2p+1}{2n+2} K(\kappa)$$

$$w_p = 2 \operatorname{cd}^2(u_0, \kappa) - 1$$

$$w_s = 2 \operatorname{cn}^2(u_0, \kappa) - 1$$

$$w_q = \frac{w_p + w_s}{2}$$

$$w_m = w_s + 2 \frac{\operatorname{sn}(u_0, \kappa) \operatorname{cn}(u_0, \kappa)}{\operatorname{dn}(u_0, \kappa)} Z(u_0, \kappa)$$

$$\alpha_n = 1, \alpha_{n+1} = \alpha_{n+2} = \alpha_{n+3} = \alpha_{n+4} = \alpha_{n+5} = 0$$

Body:

for $m = n + 2$ **down to** 3 **do**

$$8c_1 = n(n+2) - (m+3)(m+5)$$

$$4c_2 = 3w_m[n(n+2) - (m+2)(m+4)] + (m+3)(2m+7)(w_m - w_q)$$

$$8c_3 = 3[n(n+2) - (m+1)(m+3)] + 12w_m \left[(n+1)^2 w_m - (m+2)^2 w_q \right] \dots \\ - 4(m+2)(m+3)(w_p w_s - w_m w_q)$$

$$2c_4 = 3 \left[(n+1)^2 w_m - (m+1)^2 w_q \right] - (m+1)^2 (w_m - w_q) \quad \dots \\ + 2w_m \left[(n+1)^2 w_m^2 - (m+1)^2 w_p w_s \right]$$

$$8c_5 = 3[n(n+2) - (m-1)(m+1)] + 12w_m \left[(n+1)^2 w_m - m^2 w_q \right] \quad \dots \\ - 4m(m-1)(w_p w_s - w_m w_q)$$

$$4c_6 = 3w_m[n(n+2) - (m-2)m] + (m-1)(2m-3)(w_m - w_q)$$

$$8c_7 = n(n+2) - (m-3)(m-1)$$

$$\alpha_{m-3} = \frac{1}{c_7} \sum_{l=1}^6 (-1)^l c_l \alpha_{m+4-l}$$

end for

Normalisation:

$$s_n = \sum_{m=0}^n (m+1) \alpha_m$$

for $m = 0$ **to** n **do**

$$a_m^+ = (-1)^p (n+1) \frac{\alpha_m}{s_n}$$

end for

Integration:

for $m = 0$ **to** n **do**

$$a_{m+1}^+ = \frac{a_m^+}{m+1}$$

end for

Impulse response:

$$h_{n+1} = -\frac{\mathcal{N}_1}{\mathcal{N}_2 - \mathcal{N}_1}$$

for $m = 1$ **to** $n+1$ **do**

$$h_{n+1 \pm m} = \frac{1}{2} \frac{a_m}{\mathcal{N}_2 - \mathcal{N}_1}$$

end for

Vlček and *Zahradník* [99, Section 7] provide the following design procedure:

1. Specify the minimum attenuation in the stop-band, $a_{s_{dB}} = 20 \log_{10} a_s < 0$. Specify the pass-band frequency $\omega_p T$ and the stop-band frequency $\omega_s T$. The maximum width of the transition band is $\Delta\omega T = (\omega_s - \omega_p) T$.
2. Calculate the degree, $n = p + q$, of the generating polynomial, $S_{p,q}(w)$, using the approximationⁱ:

$$\frac{(\xi_1 n + \xi_2) \Delta\omega T}{\pi} + \xi_3 + \frac{\xi_4}{(n + \xi_5)^{\xi_6}} = a_{s_{dB}}$$

where $\xi_1 = -14.02925485$, $\xi_2 = -32.86119410$, $\xi_3 = -5.80117336$, $\xi_4 = 2.99564719$, $\xi_5 = -21.24188066$ and $\xi_6 = 0.28632078$.

3. Determine integer values $p = \lfloor n \frac{(\omega_s + \omega_p)T}{2\pi} \rfloor$, $q = n - p$

4. Calculate the elliptic function modulus $\kappa = \sqrt{1 - \left(\frac{1-\hat{\kappa}}{1+\hat{\kappa}}\right)^2}$, where $\hat{\kappa}$ is given by the approximation:

$$\hat{\kappa} = \left\{ \left[\chi_1 + \frac{\chi_2}{(p + \chi_3)^{\chi_4}} \right] n + \chi_5 p + \chi_6 \right\} w_p + \chi_7 + \frac{\chi_8}{(p + \chi_9)^{\chi_{10}}} + \frac{1}{(n + \chi_{11} p + \chi_{12})^{\chi_{13} p + \chi_{14}}}$$

for $w_p = \cos \frac{\pi - \Delta\omega T}{2}$ and $\chi_1 = -0.00452871$, $\chi_2 = 0.51350112$, $\chi_3 = 2.56407699$, $\chi_4 = 1.12297611$, $\chi_5 = 0.01473844$, $\chi_6 = 0.14824220$, $\chi_7 = 0.00245539$, $\chi_8 = 0.52499043$, $\chi_9 = 0.75104615$, $\chi_{10} = 1.29448910$, $\chi_{11} = -1.06038228$, $\chi_{12} = 0.64247743$, $\chi_{13} = -0.00932499$, $\chi_{14} = 1.88486768$.

5. Perform Algorithm L.7 to find the impulse response, h_m .

The Octave script *zolotarev_vlcek_zahradnik_test.m* reproduces *Vlček* and *Zahradník*'s Figures 1 to 4 [99], illustrating the design of an almost equi-ripple FIR filter with $p = 4$, $q = 11$ and $\kappa = 0.75$. Figure L.48 shows the iso-extremal function, $\sqrt{1 - w^2} S_{4,11}(w, 0.75)$, Figure L.49 shows the generating function, Figure L.50 shows zero-phase transfer function and Figure L.51 shows the amplitude frequency response. The coefficients of the expansion of the zero-phase response in Chebyshev polynomials of the first kind found with Algorithm L.7 [99, Table 4] are:

```
a_4_11 = [ 0.3018151112, 0.4512145672, 0.2822759289, 0.0868799820, ...
-0.0561809419, -0.1053948923, -0.0720513180, -0.0045415003, ...
0.0453863810, 0.0518476231, 0.0229242778, -0.0132284961, ...
-0.0312378770, -0.0240752981, -0.0030110098, 0.0144231969, ...
0.0529542655 ];
```

The corresponding z -domain discrete-time impulse response coefficients are:

```
h_4_11 = [ 0.0264771327, 0.0072115984, -0.0015055049, -0.0120376491, ...

```

The Octave script *zolotarev_vlcek_zahradnik_test.m* also reproduces *Vlček* and *Zahradník*'s Figure 5, shown here as Figure L.52.

Finally, the Octave script *zolotarev_vlcek_zahradnik_test.m* follows the procedure of *Vlček* and *Zahradník* to design a low-pass FIR filter with $a_{s_{dB}} = -120$, $f_p = 0.15$ and $f_s = 0.175$ [99, Section 8]. For this filter $n = 162$, $p = 53$, $q = 109$ and the filter length is 327. The value of the elliptic modulus calculated in the script, $\kappa = 0.5605516759$, differs slightly from that reported by *Vlček* and *Zahradník*, $\kappa = 0.55830966$. This may be due to round-off error in the given values of χ . The frequency response of the filter is shown in Figure L.53.

ⁱI found that, for a filter with $a_{s_{dB}} = -100$, $f_p = 0.24$ and $f_s = 0.25$, the degree equation of *Vlček* and *Zahradník* [99, Equation 23] grossly over-estimates the required n as $n = 336$ when $n = 198$ is sufficient.

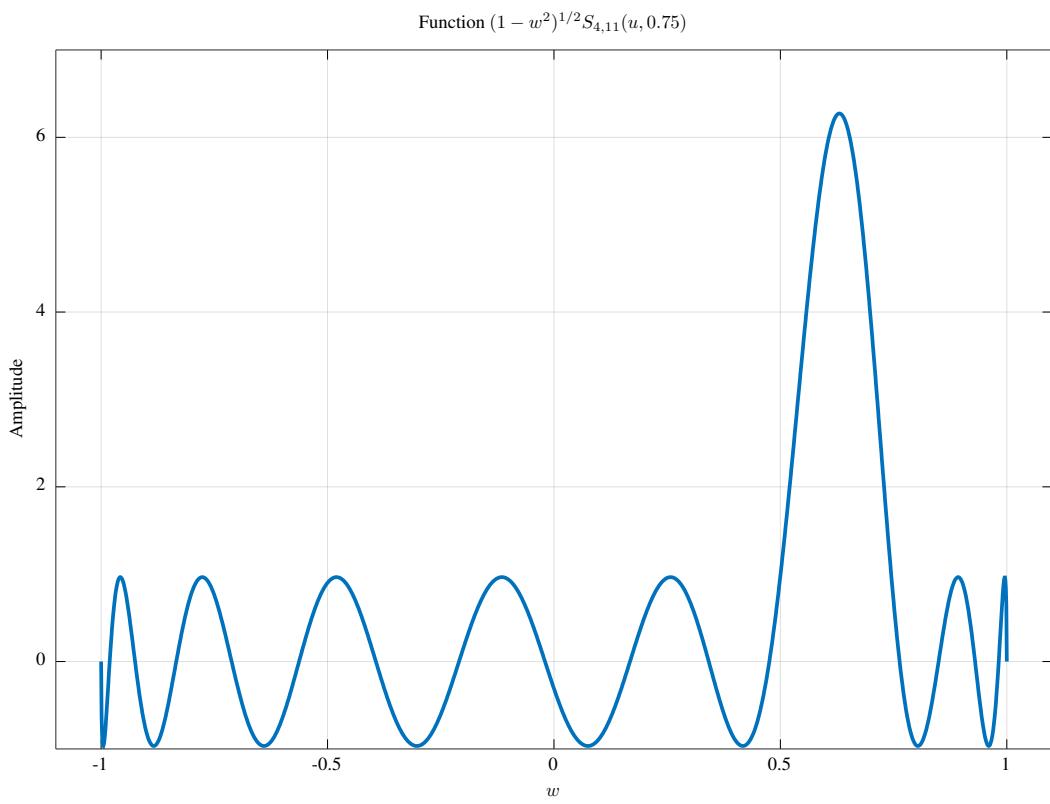

Figure L.48: Iso-extremal function $\sqrt{1 - w^2} S_{4,11}(w, 0.75)$, corresponding to Figure 1 of Vlček and Zahradník [99], $p = 4$, $q = 11$, $\kappa = 0.75$

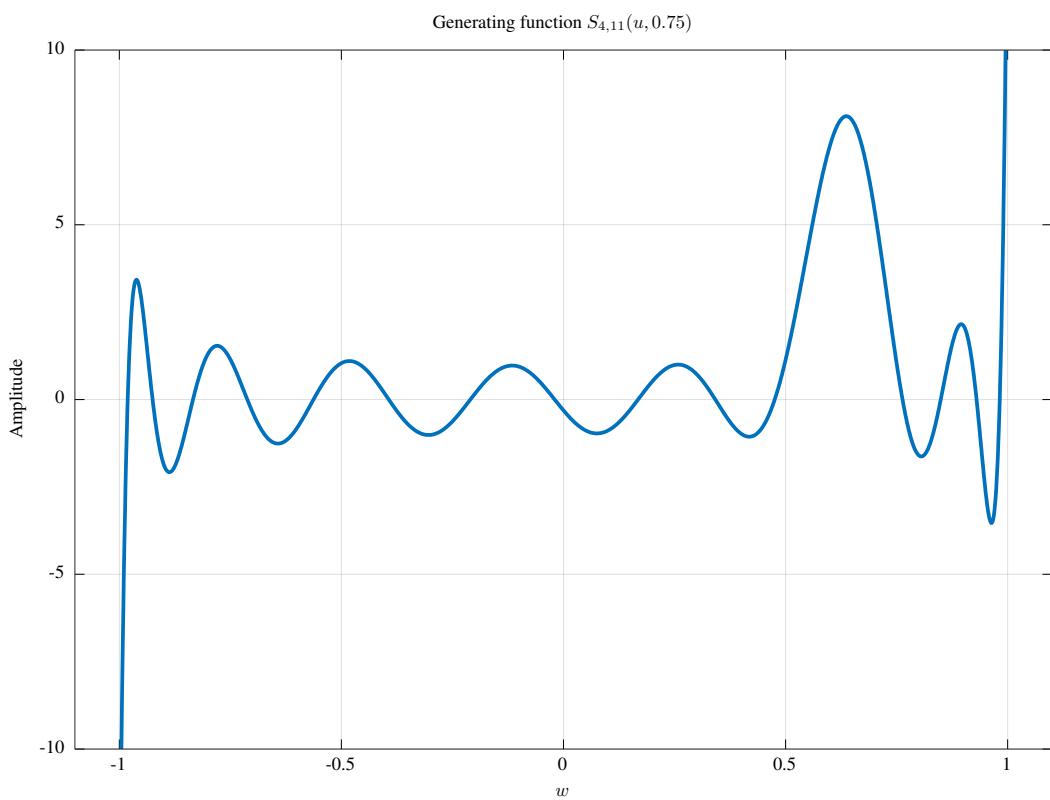

Figure L.49: FIR filter generating function corresponding to Figure 2 of Vlček and Zahradník [99], $p = 4$, $q = 11$, $\kappa = 0.75$

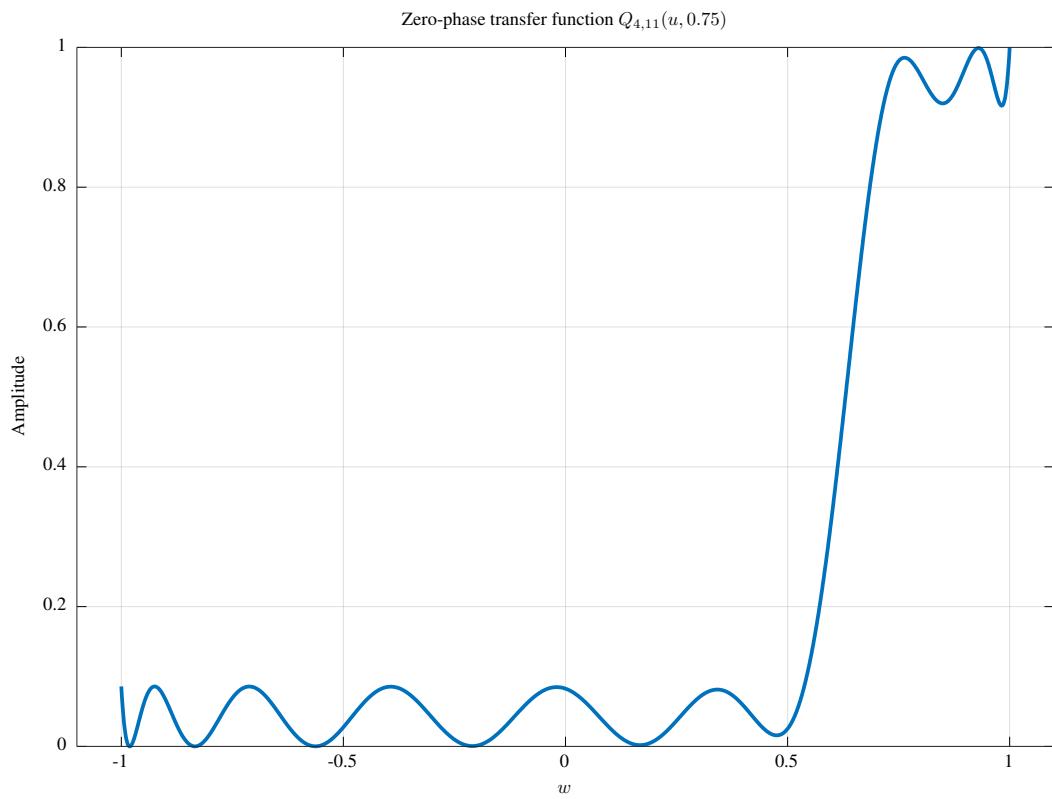

Figure L.50: FIR filter zero-phase response corresponding to Figure 3 of Vlček and Zahradník [99], $p = 4, q = 11, \kappa = 0.75$

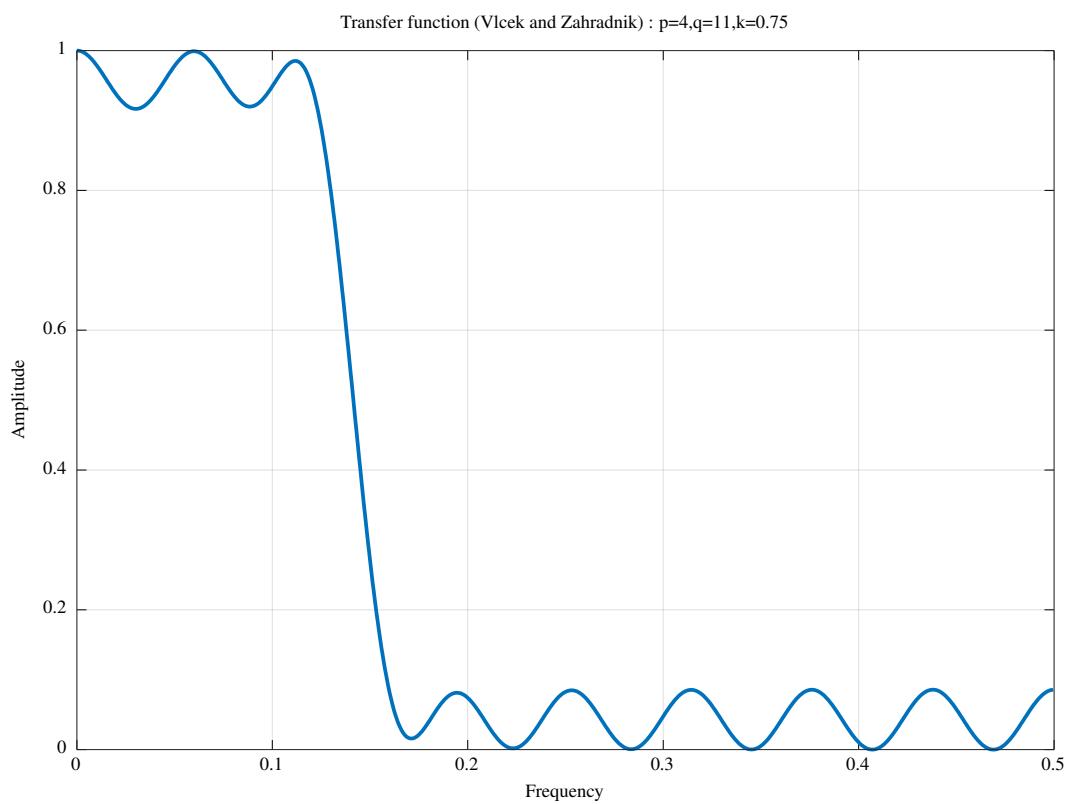

Figure L.51: FIR filter amplitude response corresponding to Figure 4 of Vlček and Zahradník [99], $p = 4, q = 11, \kappa = 0.75$

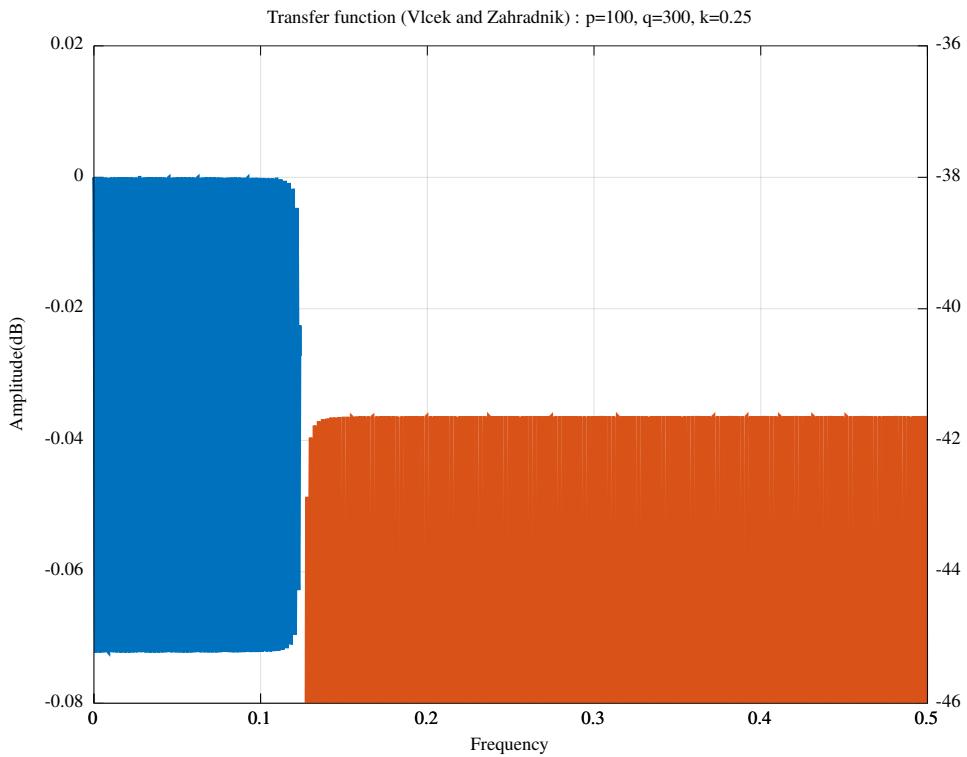

Figure L.52: FIR filter amplitude response corresponding to Figure 5 of Vlček and Zahradník [99], $p = 100$, $q = 300$, $\kappa = 0.25$

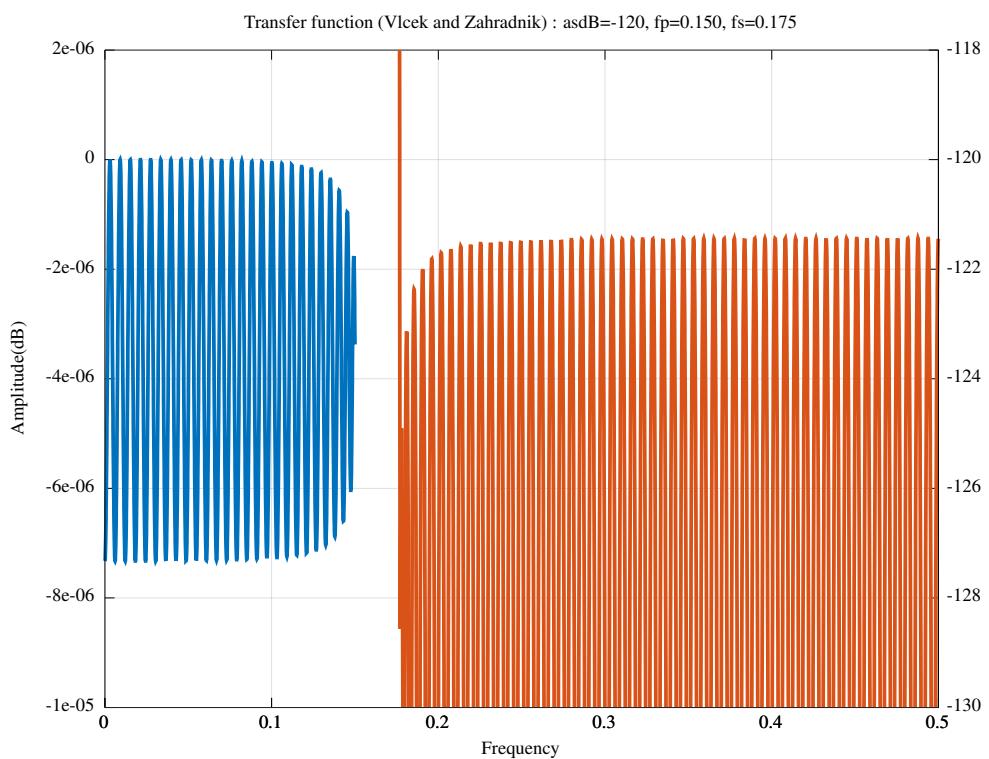

Figure L.53: FIR filter amplitude response of a low-pass FIR filter with $a_{dB} = -120$, $f_p = 0.15$ and $f_s = 0.175$ designed with the procedure of Vlček and Zahradník [99, Section 8]

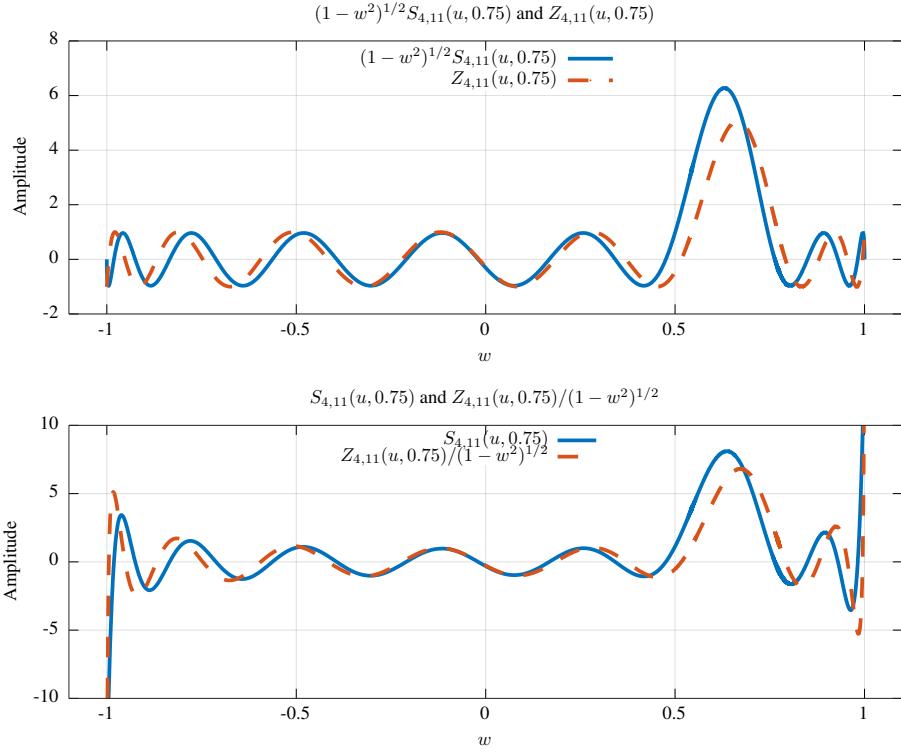

Figure L.54: Comparison of the iso-extremal function, $\sqrt{1 - w^2}S_{4,11}(w, 0.75)$, the Zolotarev polynomial, $Z_{4,11}(w, 0.75)$, calculated by the Chebyshev expansion by Vlček and Unbehauen [96], the generating function, $S_{4,11}(w, 0.75)$, of Vlček and Zahradník [99] and the modified Zolotarev polynomial, $Z_{4,11}(w, 0.75) / \sqrt{1 - w^2}$.

Addendum

I can successfully design filters with Table 4 of Vlček and Zahradník [99]. On the other hand, I find that the generating function, $S_{p,q}(w, \kappa)$, calculated by Table 4, does not satisfy their Equation 17. Figure L.54, created by the Octave script *zolotarev_vlcek_zahradnik_test.m*, compares the Zolotarev polynomial, $Z_{4,11}(w, 0.75)$, found by direct calculation [169], the modified Zolotarev polynomial, $Z_{4,11}(w, 0.75) / \sqrt{1 - w^2}$, the function, $\sqrt{1 - w^2}S_{4,11}(w, 0.75)$, and the generating polynomial $S_{4,11}(w, 0.75)$.

I am not sure what Vlček and Zahradník [99, p.747] mean by “the second solution of (14) in the form $\sqrt{1 - w^2}S_{p,q}(w, \kappa)$ ”. Initially, I assumed that they are referring to the possibility of a second, linearly independent solution of Equation L.25^j. However, after examining Figure L.48 [99, Figure 1], it is clear that $\sqrt{1 - w^2}S_{p,q}(w, \kappa)$ is not a solution of Equation L.24, as it is zero rather than ± 1 at $w = \pm 1$, as shown for $Z_{5,9}(w, 0.78)$ in Figure L.36. Vlček and Zahradník’s Table 4 shows that the main lobe edge is modified to $u_0 = \frac{p+\frac{1}{2}}{n+1}K(\kappa)$. This suggests that the n^2 term in Equation L.25 should be replaced by $(n + 1)^2$. The Maxima script *zolotarev_vlcek_zahradnik_table_4.max* substitutes $\sqrt{1 - w^2}f(w)$ into Equation L.25 with this modification. The resulting differential equation is^k:

$$g_2(w) \left[(1 - w^2) \frac{d^2 f}{dw^2} - 3w \frac{df}{dw} \right] - g_1(w) (1 - w^2) \frac{df}{dw} + \left[(n + 1)^2 g_0(w) + w g_1(w) - g_2(w) \right] f = 0 \quad (\text{L.37})$$

The Octave script *zolotarev_vlcek_zahradnik_test.m* shows that the $S_{p,q}(w, \kappa)$ function calculated by Table 4 of Vlček and Zahradník satisfies this differential equation.

The Chebyshev polynomials of the second kind, $U_m(w)$, satisfy the differential equation:

$$(1 - w^2) \frac{d^2 U_m(w)}{dw^2} - 3w \frac{dU_m(w)}{dw} + m(m + 2) U_m(w) = 0$$

Differentiating $U_m(w)$ gives:

$$(1 - w^2) \frac{dU_m(w)}{dw} = (m + 2) w U_m(w) - (m + 1) U_{m+1}(w)$$

^jFor example, see Morse and Feshbach [110, Section 5.2].

^kConsistent with Equation L.26 rather than following the changes in notation from Vlček and Unbehauen [96, Equation 64] to Vlček and Unbehauen [99, Equation 15].

The Chebyshev polynomials of the second kind obey the following relations:

$$\begin{aligned} 2wU_m(w) &= U_{m+1}(w) + U_{m-1}(w) \\ 4w^2U_m(w) &= U_{m+2}(w) + 2U_m(w) + U_{m-2}(w) \\ 8w^3U_m(w) &= U_{m+3}(w) + 3U_{m+1}(w) + 3U_{m-1}(w) + U_{m-3}(w) \\ &\vdots \end{aligned}$$

The linear differential equation for $S_{p,q}(w, \kappa)$ can be solved by substituting an expansion in Chebyshev polynomials of the second kind:

$$S_{p,q}(w) = \sum_{m=0}^n a_m^+ U_m(w)$$

so that:

$$\begin{aligned} &-g_2(w) \sum_{m=0}^n m(m+2) a_m^+ U_m(w) \dots \\ &-g_1(w) \sum_{m=0}^n a_m^+ [(m+2)wU_m(w) - (m+1)U_{m+1}(w)] \dots \\ &+ \left[(n+1)^2 g_0(w) + w g_1(w) - g_2(w) \right] \sum_{m=0}^n a_m^+ U_m(w) = 0 \end{aligned} \tag{L.38}$$

The Maxima script *zolotarev_vlcek_zahradnik_table_4.max* calculates the recurrence relations from Equation L.38. The results agree with Table 4 of Vlček and Zahradník [99] when inserted into the Octave function *zolotarev_vlcek_zahradnik.m*.

Appendix M

Application of the *Kalman-Yakubovič-Popov* lemma to IIR filter design

The *Kalman-Yakubovič-Popov* (KYP) lemma [131] is a fundamental result from the theory of control systems. The continuous time KYP states that, for a state-variable system with $A \in \mathbb{C}_{n \times n}$ and (A, B) controllable, the frequency domain inequality(FDI):

$$\begin{bmatrix} (\imath\omega I - A)^{-1} B \\ I \end{bmatrix}^\dagger \Theta \begin{bmatrix} (\imath\omega I - A)^{-1} B \\ I \end{bmatrix} \leq 0 \quad \omega \in \mathbb{R} \cup \{\infty\} \quad (\text{M.1})$$

holds if and only if the following linear matrix inequality(LMI) is feasible for a solution $P \in \mathbf{H}_n$, the set of Hermitian $n \times n$ matrixes:

$$\begin{bmatrix} A^\dagger P + PA & PB \\ B^\dagger P & 0 \end{bmatrix} + \Theta \preceq 0 \quad (\text{M.2})$$

For the purposes of filter design, the lemma states that an infinite dimension frequency response constraint is equivalent to a constraint on the coefficients of the state space description. If $H(\omega) = C(\imath\omega I - A)^{-1} B + D$ is the transfer function of the filter with $A \in \mathbb{R}_{n \times n}$, then we can write:

$$\Theta = \begin{bmatrix} C & D \\ 0 & I \end{bmatrix}^T \Pi \begin{bmatrix} C & D \\ 0 & I \end{bmatrix}$$

For example, if $\Pi = \begin{bmatrix} I & 0 \\ 0 & -\gamma^2 I \end{bmatrix}$ then the corresponding frequency domain constraint is $|H(\omega)|^2 \leq \gamma^2$ ^a. The KYP lemma has been generalised to discrete time state variable systems and to unions of frequency domain inequalities [39, 151, 152, 40]. If the filter parameter vector is $\rho \in \mathbb{R}_p$, then the LMI of Equation M.2 corresponds to an SDP optimisation problem with $p + \frac{n(n+1)}{2}$ variables. Vandenburghe *et al.* [82] show that it is more efficient to solve the *dual* or *primal-dual* SDP problems. In the following three sections I follow Iwasaki and Hara [151].

M.1 The S-procedure

The so-called *S-procedure* forms the basis of proofs of the KYP lemma. It “converts a constrained inequality to an unconstrained inequality with multipliers”. The classic version of the S-procedure asserts that, given matrixes $\Theta, M \in \mathbf{H}_n$, the following statements are equivalent:

$$\xi^* \Theta \xi \preceq 0 \quad \forall \xi \in \mathbb{C}_n \text{ such that } \xi^* M \xi \succeq 0 \quad (\text{M.3a})$$

^aIf $H(\omega)$ is single-input-single-output, the desired frequency response is $H_D(\omega)$ and if

$$\Pi = \begin{bmatrix} 1 & -H_D(\omega) \\ -H_D^\dagger(\omega) & |H_D(\omega)|^2 - \gamma^2 \end{bmatrix}$$

then the corresponding frequency domain constraint is $|H(\omega) - H_D(\omega)|^2 \leq \gamma^2$. Similarly, if

$$\Pi = \begin{bmatrix} 1 & 0 \\ 0 & -|H_D(\omega)|^2 - \gamma^2 \end{bmatrix}$$

then $|H(\omega)|^2 - |H_D(\omega)|^2 \leq \gamma^2$.

$$\exists \tau \in \mathbb{R} \text{ such that } \tau \geq 0 \text{ and } \Theta + \tau M \preceq 0 \quad (\text{M.3b})$$

where ξ^* is the *Moore-Penrose* inverse. The S-procedure replaces the condition of Equation M.3a with that of Equation M.3b. The latter condition is easier to satisfy as it is a search for the scalar multiplier, τ , satisfying convex constraints. *Iwasaki* and *Hara* [151, Section II.A] write an alternative definition of the S-procedure:

$$\begin{aligned} \mathbf{M} &:= \{\tau M : \tau \in \mathbb{R}, \tau \geq 0\} \\ \mathbf{N} &:= \{N : N = N^* \preceq 0\} \\ \mathcal{S} &:= \xi \xi^* \\ \mathbf{S}(\mathbf{M}) &:= \{\mathcal{S} \in \mathbf{H}_n : \mathcal{S} \neq 0, \mathcal{S} \succeq 0, \text{trace}(\mathbf{MS}) \geq 0\} \\ \mathbf{S}_1 &:= \{\mathcal{S} \in \mathbf{S}(\mathbf{M}) : \text{rank}(\mathcal{S}) = 1\} \\ \text{trace}(\Theta \mathbf{S}_1) \leq 0, \forall \mathcal{S} \in \mathbf{S}_1 &\Leftrightarrow (\Theta + \mathbf{M}) \cap \mathbf{N} \neq \emptyset \\ \text{trace}(\Theta \mathbf{S}_1) \leq 0, \forall \mathcal{S} \in \mathbf{S}_1 &\Leftrightarrow (\Theta + \mathbf{M}) \cap \text{interior}(\mathbf{N}) \neq \emptyset \end{aligned}$$

The S-procedure is said to be *loss-less* if the equivalence holds in both directions. *Iwasaki* and *Hara* [151, Section II.B] make the following definitions:

Definition 1: A set $\mathbf{M} \subset \mathbf{H}_n$ is:

- *admissible* if it is a non-empty closed convex cone and $\text{interior}(\mathbf{N}) \cap \mathbf{M} = \emptyset$
- *regular* if $\mathbf{N} \cap \mathbf{M} = \{0\}$
- *rank-one-separable* if $\mathbf{S} = \text{convexhull}(\mathbf{S}_1)$

and prove the following theorem:

Theorem 1 (S-procedure): Let an admissible and regular set $\mathbf{M} \subset \mathbf{H}_n$ be given then the S-procedure is lossless for arbitrary $\Theta \in \mathbf{H}_n$, if-and-only-if \mathbf{M} is rank-one-separable.

and lemma:

Lemma 1: Let $\mathbf{M} \subset \mathbf{H}_n$ be a rank-one-separable set. Then the set $F^*MF + \mathbf{P}$ is rank-one-separable for any matrix $F \in \mathbb{C}^{n \times m}$ and subset $\mathbf{P} \subset \mathbf{H}_n$ of positive-semidefinite matrixes containing the origin.

M.2 Frequency ranges as curves in the complex plane

The frequency response constraint example in the previous section applies to the whole of the positive $i\omega$ axis in the continuous-time *s-plane*. For a discrete-time filter, the frequency response constraints are defined over a union of frequencies on the unit-circle in the *z-plane*. *Iwasaki* and *Hara* [151, Section IV] define a curve in the complex plane as:

Definition 2: A curve on the complex plane is a collection of infinitely many points $\lambda(t) \in \mathbb{C}$ continuously parameterized by t for $t_o \leq t \leq t_f$ where $t_o, t_f \in \mathbb{R} \cup \{\pm\infty\}$ and $t_o < t_f$.

Iwasaki and *Hara* consider the class of curves:

$$\Lambda(\Phi, \Psi) := \{\lambda \in \mathbb{C} : \sigma(\lambda, \Phi) = 0, \sigma(\lambda, \Psi) \geq 0\}$$

where $\Phi, \Psi \in \mathbf{H}_2$. If $G \in \mathbb{C}_{n \times m}$ and $\Pi \in \mathbf{H}_{n+m}$, then *Iwasaki* and *Hara* define the function $\sigma : \mathbb{C}_{n \times m} \times \mathbf{H}_{n+m} \mapsto \mathbf{H}_m$ by:

$$\sigma(G, \Pi) := \begin{bmatrix} G \\ I_m \end{bmatrix}^* \Pi \begin{bmatrix} G \\ I_m \end{bmatrix}$$

In this case $n = m = 1$.

The set $\Lambda(\Phi, 0)$ represents a curve if-and-only-if $\det(\Phi) < 0$. For example,

$$\sigma\left(\lambda, \begin{bmatrix} 1 & -\lambda_c \\ -\lambda_c^* & |\lambda_c|^2 - r^2 \end{bmatrix}\right) = |\lambda - \lambda_c|^2 - r^2 = 0$$

defines a circle with radius r centred at λ_c and

$$\sigma\left(\lambda, \begin{bmatrix} 0 & a + ib \\ a - ib & 2c \end{bmatrix}\right) = 2(a\Re\lambda + b\Im\lambda + c) = 0$$

defines a straight line with the normal vector $a + ib \neq 0$. The set $\Lambda(0, \Psi)$ represents a region in the complex plane with boundary $\Lambda(\Psi, 0)$ whenever $\det(\Psi) < 0$.

M.3 A generalised KYP lemma

M.4 Efficient solution of SDP problems arising from the KYP lemma

Colophon

Software requirements

I currently use the Fedora 30 distribution of Linux with:

- *gcc version 9.1.1 20190503 (Red Hat 9.1.1-1)*
- a local build of *octave-5.1.0* with the *struct*, *io*, *statistics*, *optim*, *control*, *signal* and *parallel* Octave-Forge packages
- the *octave* scripts use the *gnuplot* graphics toolkit and *gnuplot-5.0 patchlevel 6*
- *texlive-2018-25* and various packages are installed
- *dia-0.97.3* is used for line drawings

Makefile

This document is built with *GNU make-4.2.1*. The *Makefile* in the project archive builds the PDF version of this document from the *L^AT_EX* source in *DesignOfIIRFilters.tex*. The project archive contains the files required to generate the figures shown in this document. The line diagrams are in *dia* format [43] in directory *fig*. The source code is in directory *src*. The source code languages are C++, Maxima and Octave. The *Makefile* includes a *.mk* file for each of the Octave test script dependencies listed in the variable *OCTAVE_SCRIPTS*. For example, the Octave script *butt3NS_test.m*, referred to in Section 5.7.1, has the corresponding *Makefile* fragment, *butt3NS_test.mk*:

```
butt3NS_test_FIGURES=butt3NS_test_response \
butt3NS_test_expected_response \
butt3NS_test_response_direct_form_noise \
butt3NS_test_sv_noise_schur_lattice \
butt3NS_test_sv_noise_global_optimum \
butt3NS_test_sv_noise_direct_form \
butt3NS_test_sv_sine_schur_lattice

butt3NS_test_FILES = \
butt3NS_test.m test_common.m schurexpand.oct schurdecomp.oct \
schurNSScale.oct tf2schurNSlattice.m schurNSlatticeNoiseGain.m \
schurNSlattice2Abcd.oct schurNSlatticeFilter.m svf.m KW.m optKW.m \
tf2Abcd.m crossWelch.m
```

Building this document may take a long time. I run *make -j 6*.

Octave

The *build-octave.sh* script builds a local, command-line only, version of *octave-5.1.0* avoiding the vagaries of the Fedora packagers^b. The local build of Octave links to locally built versions of the following libraries: *arpack-ng-master* [10], *fftw-3.3.8* [37], *glpk-4.65* [127], *lapack-3.8.0* [83], *qrupdate-1.1.2* [128] and *SuiteSparse-4.5.6* [150].

^bThe Fedora 28 *octave-4.2.2-1.fc28* package depends on the Netlib, ATLAS and OpenBLAS versions of the *blas* and *lapack* libraries.

The *build-octave.sh* script assumes that the *wget*, *gnuplot-latex*, *readline-devel*, *lzip*, *sharutils*, *gfortran* and *cmake* utilities are installed.

The Octave version and list of installed Octave Forge packages used to build this document are:

```
computer=x86_64-pc-linux-gnu
octave version=5.1.0 (HG-ID=d05d6eebde10)
Package Name | Version | Installation directory
-----+-----+-----
control *| 3.2.0 | .../octave-5.1.0/share/octave/packages/control-3.2.0
io *| 2.4.12 | .../local/octave-5.1.0/share/octave/packages/io-2.4.12
optim *| 1.6.0 | .../octave-5.1.0/share/octave/packages/optim-1.6.0
parallel | 3.1.3 | .../octave-5.1.0/share/octave/packages/parallel-3.1.3
signal *| 1.4.1 | .../octave-5.1.0/share/octave/packages/signal-1.4.1
statistics *| 1.4.1 | .../share/octave/packages/statistics-1.4.1
struct *| 1.0.16 | .../octave-5.1.0/share/octave/packages/struct-1.0.16
```

The *signal-1.4.1* package *zplane.m* function is patched to avoid a L^AT_EX error. The *parallel-3.1.3* package is patched to make it compatible with *octave-5.1.0*.

The section *Summary of important user-visible changes for version 4.0* in the *NEWS* file of the Octave source distribution includes the following comment:

Octave now automatically truncates intermediate calculations done with floating point values to 64 bits. Some hardware math co-processors, such as the x87, maintain extra precision, but this leads to disagreements in calculations when compared to reference implementations in software using the IEEE standard for double precision. There was no measurable performance impact to this change, but it may be disabled with the configure option `--disable-float-truncate`. MinGW and Cygwin platforms, as well as GCC compilers ≥ 5.0 require this feature. Non-x87 hardware, or hardware using SSE options exclusively, can disable float truncation if desired.

This project includes a number of Octave *oct-file* extensions written in C++. The Octave on-line FAQ states:

Code written using Octave's native plug-in interface (also known as a *.oct* file) necessarily links with Octave internals and is considered a derivative work of Octave and therefore must be released under terms that are compatible with the GPL.

The *fftw-3.3.8* release notes (May 28th, 2018-2019) state:

Fixed AVX, AVX2 for gcc-8. By default, FFTW 3.3.7 was broken with gcc-8. AVX and AVX2 code assumed that the compiler honors the distinction between +0 and -0, but gcc-8 -ffast-math does not. The default CFLAGS included -ffast-math . This release ensures that FFTW works with gcc-8 -ffast-math , and removes -ffast-math from the default CFLAGS for good measure.

Building Octave

Building Octave with LTO and PGO

The following commands build Octave linked with the system *lapack* and *blas* shared libraries with link-time-optimisation (LTO) and profile-guided-optimisation (PGO):

```
#!/bin/sh

BLDOPTS="-m64 -mtune=generic -O2"
export CFLAGS="-I$LOCAL_PREFIX/include -std=c11 \"$BLDOPTS"
export CXXFLAGS="-I$LOCAL_PREFIX/include -std=c++11 \"$BLDOPTS"
export FFLAGS=$BLDOPTS
export LDFLAGS="-L$LAPACK_DIR -L$LOCAL_PREFIX/lib"
```

```

$OCTAVE_DIR/configure $OCTAVE_CONFIG_OPTIONS \
--prefix=$OCTAVE_INSTALL_DIR --with-blas="-lblas" --with-lapack="-llapack"

export PGO_GEN_FLAGS="-pthread -fopenmp -fprofile-generate"
make XTRA_CFLAGS=$PGO_GEN_FLAGS XTRA_CXXFLAGS=$PGO_GEN_FLAGS V=1 -j6
find . -name \*.gcda -exec rm {} ';' ;
make V=1 -j6 check
find . -name \*.o -exec rm -f {} ';' ;
find . -name \*.lo -exec rm -f {} ';' ;
find . -name \*.la -exec rm -f {} ';' ;
export PGO_LTO_FLAGS="-pthread -fopenmp -fprofile-use -flto=6 -ffat-lto-objects"
make XTRA_CFLAGS="$PGO_LTO_FLAGS" XTRA_CXXFLAGS="$PGO_LTO_FLAGS" V=1 -j6

```

The PGO profile information is generated by running the Octave test suite.

Building Octave for debugging

```

#!/bin/sh

BLDOPTS="-m64 -O0"
export CFLAGS="-I$LOCAL_PREFIX/include -std=c11 -ggdb3 \"$BLDOPTS"
export CXXFLAGS="-I$LOCAL_PREFIX/include -std=c++11 -ggdb3 \"$BLDOPTS"
export FFLAGS="-ggdb3 \"$BLDOPTS"
export LDFLAGS="-L$LAPACK_DIR -L$LOCAL_PREFIX/lib"

$OCTAVE_DIR/configure $OCTAVE_CONFIG_OPTIONS \
--prefix=$OCTAVE_INSTALL_DIR --with-blas="-lblas" --with-lapack="-llapack"

make V=1 -j 6

```

Do not use the Octave configure script flag *-enable-address-sanitizer-flags* with *valgrind*.

To build and test an oct-file with *address-sanitizer*:

```

mkoctfile -g -O0 -fsanitize=address -fsanitize=undefined \
-fno-sanitize=vptr -fno-omit-frame-pointer an_oct_file.cc
LD_PRELOAD=/usr/lib64/libasan.so.5 octave-cli --eval 'an_oct_file_test_script'

```

Installing Octave-Forge packages

To install Octave packages from a remote Octave-Forge file-server:

```
octave-cli --eval 'pkg install -forge struct io statistics optim control signal'
```

If *octave* was configured with *-disable-docs* then packages can be installed with this work-around:

```
/usr/local/octave-dbg/bin/octave-cli \
--eval 'texi_macros_file("/dev/null"); pkg install package_file_name'
```

Benchmarking Octave

This section shows the results of benchmarking various builds of Octave and benchmarking *blas* and *lapack* libraries with a shared library *LTO* and *PGO* build of Octave. The Linux kernel used is *5.0.3-200.fc29.x86_64* from the RedHat Fedora 29 Linux distribution. The system compiler is *gcc version 8.3.1 20190223 (Red Hat 8.3.1-2)*. The CPU is an Intel i7-7700K for which the number of CPU cores is 4 (8 hyper-threaded). During the benchmark the CPU frequency was fixed at *4.5GHz*. To do this, as the *root* user:

```

for c in `seq 0 7`;do
  echo "4500000" > /sys/devices/system/cpu/cpu$c/cpufreq/scaling_min_freq;
  echo "performance" > /sys/devices/system/cpu/cpu$c/cpufreq/scaling_governor;
done
cpupower -c all frequency-info

```

Octave build	IIR benchmark execution time (seconds)
Debug, shared reference lapack and blas	123.8
Generic, shared reference lapack and blas	39.5
Generic, shared reference lapack and blas, LTO	39.0
Generic, shared reference lapack and blas, PGO	37.7
Generic, shared reference lapack and blas, LTO, PGO	37.4

Table M.1: Average execution time for 10 runs of IIR benchmark scripts with various *Octave* builds.

Benchmarking Octave builds

The shell script *benchmark/build-benchmark.sh* generates the Octave builds shown in Table M.1. It is assumed to run in the *benchmark* sub-directory. The Octave build benchmark test loops 100 times finding the amplitude, group delay and phase response of a filter. Numerical differences between the *blas* and *lapack* implementations make it impossible to usefully benchmark with a filter design script like *iir_sqp_slb_bandpass_test.m* or *decimator_R2_test.m*. The times given are the average of 10 runs. For the *debug* build the optimisation level is *-O0* and for the other builds it is *-O2 -m64 -mtune=generic*. The Octave build is configured for command-line only and local libraries with the folowing options:

```
export OCTAVE_CONFIG_OPTIONS=" \
--disable-docs \
--disable-java \
--disable-atomic-refcount \
--without-fltk \
--without-qt \
--without-sndfile \
--without-portaudio \
--without-qhull \
--without-magick \
--without-glpk \
--without-hdf5 \
--with-arpack-includedir=$LOCAL_PREFIX/include \
--with-arpack-libdir=$LOCAL_PREFIX/lib \
--with-qrupdate-includedir=$LOCAL_PREFIX/include \
--with-qrupdate-libdir=$LOCAL_PREFIX/lib \
--with-amd-includedir=$LOCAL_PREFIX/include \
--with-amd-libdir=$LOCAL_PREFIX/lib \
--with-camd-includedir=$LOCAL_PREFIX/include \

```

Benchmarking *blas* and *lapack* libraries

The shell script *library-benchmark.sh* benchmarks the shared library *LTO* and *PGO* version of Octave with the *linpack.m* [89] script and the previous IIR benchmark script. The *linpack.m* script was modified to produce repeatable residuals. The alternative *blas* and *lapack* library versions used are local builds of *blas-3.8.0* and *lapack-3.8.0* and the Fedora 29 *lapack*, *blas*, *atlas*[12], *gsl*[125] and *openblas*[106] packages:

atlas.x86_64	3.10.3-6.fc29
blas.x86_64	3.8.0-10.fc29

blas library	linpack.m		IIR benchmark script
	MFLOPS	Normalised residual	Execution time (seconds)
Generic libblas/liblapack	4032	17.7	37.3
Intel libblas/liblapack	4026	17.7	37.3
Haswell libblas/liblapack	4067	15.1	37.4
Nehalem libblas/liblapack	4037	17.7	37.3
Skylake libblas/liblapack	4870	15.1	37.1
Fedora 29 libblas/liblapack	4038	17.7	37.3
libgslcblas	4034	17.7	37.3
libsatlas	13915	11.5	37.5
libatlas	21518	11.6	36.9
libopenblas (1 thread)	34367	9.3	35.5
libopenblas (2 threads)	48259	11.8	35.7
libopenblas (4 threads)	59752	9.1	35.6

Table M.2: Benchmark results for *linpack.m* and IIR benchmark with various *blas* and *lapack* implementations.

```

gsl.x86_64          2.4-7.fc29
gsl-devel.x86_64    2.4-7.fc29
lapack.x86_64       3.8.0-10.fc29
openblas.x86_64     0.3.5-5.fc29
openblas-threads.x86_64 0.3.5-5.fc29

```

The library to be used is specified by the *LD_PRELOAD* environment variable. For example:

```
LD_PRELOAD=/usr/lib64/libgslcblas.so.0 octave-cli -q linpack.m
```

The number of threads used by *libatlas* was set at compile-time by the package builder. For *libopenblas*, the number of threads is set to, for example 2, by:

```
export OPENBLAS_NUM_THREADS=2
```

Table M.2 shows the average MFLOPS or execution time for 10 runs of each test using the shared library *PGO* and *LTO* build of Octave.

SeDuMi

The “official” SeDuMi source is available from *LeHigh University* as *SeDuMi_1_3.zip* [149]. Unfortunately, this version does not seem to be actively maintained and is not compatible with Octave without minor edits for various “MATLABisms”. A fork is available on *GitHub* as *sedumi-master.zip* [148]. The *GitHub* version is compatible with Octave. The *GitHub git* repository can be copied with:

```
git clone https://github.com/sqlp/sedumi.git
```

I have patched the *GitHub* version to fix some bugs and to remove some of the warning messages that occur when compiling the *mex* files. The patch file, *sedumi_master.patch*, was created from the *GitHub* version, *sedumi-master.zip* [148], as follows:

```
for file in `ls -1 SeDuMi_1_3/*.[cm]`;do \
diff -wBbEq $file sedumi-master/`basename $file`; \
if test $? -ne 0;then \
diff -wBbErupN sedumi-master/`basename $file` $file >> sedumi_master.patch; \
fi;
done
```

The local bug-fixes are in the file *blkchol2.c* in function *cholonBlk* and in the file *eigK.m*. The change in *cholonBlk* fixes an off-by-one error in the access to *x+inz+1* [42]. This bug appears in both the *GitHub* and *LeHigh* versions. The edited version of *blkchol2.c* has the following *git diff*:

```
diff --git a/blkchol2.c b/blkchol2.c
index dc798d6..19761b4 100644
--- a/blkchol2.c
+++ b/blkchol2.c
@@ -113,16 +113,16 @@ void cholonBlk(double *x, double *d, mwIndex m, const mwIndex ncols
----- */
xkk = x[inz];
if(xkk > lb[k]) { /* now xkk > 0 */
- if(xkk < ub) {
+ if((m>1) && (xkk < ub)) {
ubk = maxabs(x+inz+1,m-1) / maxu;
if(xkk < ubk) {
```

The change to *eigK.m* is that suggested in *Note4* of *SparsePOP302/readme.txt*. *SparsePOP* examples will fail without it. This bug appears only in the *GitHub* version.

The *SeDuMi* source depends on the OpenBLAS *f77blas.h* and *openblas_config.h* headers. A 64-bit version of *SeDuMi* requires *-DOPENBLAS_USE64BITINT*.

SparsePOP

SparsePOP302 [54] compiles and runs on Octave with the minor modifications to *my_unique.m*, *compileSparsePOP.m* and *sparsePOP.m* shown in *SparsePOP302.patch*.

MPSolve

Install *MPSolve* [24] as follows:

```
tar -xf mpsolve-3.1.5.tar.bz2
cd mpsolve-3.1.5
./configure --prefix=/usr/local/octave --enable-octave
make
make install
octave-cli --eval 'pkg install examples/octave/mpsolve.tar.gz'
```

An example of using *mps_roots*, the quad-float implementation in *qroots* and the built-in Octave *roots*:

```
LD_LIBRARY_PATH=/usr/local/octave/lib octave-cli \
--eval 'pkg load mpsolve;norm(mps_roots(bincoeff(20,0:20))+1)'
ans = 1.1939e-13

octave-cli -p src --eval 'norm(qroots(bincoeff(20,0:20))+1)'
ans = 0.19206

octave-cli --eval 'norm(roots(bincoeff(20,0:20))+1)'
ans = 1.4835
```

Unfortunately, I found that the results of *mps_roots* are not repeatable.

Testing

The *test* directory contains regression test shell scripts. The test scripts must be run from the project root directory. The shell script *batchtest.sh* runs multiple tests in parallel.

Windows10 with “*ubuntu on Windows*”

I have built this document in a “*ubuntu on Windows*” terminal running the 14.04.5 LTS Ubuntu release. The following tools and libraries were built from source:

- *gcc-6.3.0* with *configure* options *-enable-languages='c,c++,fortran' -disable-multilib*
- *make-4.2.1* (run *make-4.2.1* NOT the system *make* to build this document)
- *lapack-3.6.1* with deprecated routines
- *SuiteSparse-4.5.5*
- *qrupdate-1.1.2*
- *arpack-ng-master*
- *fftw-3.6.6* with *configure* options *-enable-shared -with-combined-threads -enable-threads* and with and without *-enable-single*
- *octave-4.2.1* with the following *configure* options:
*--disable-java --without-fltk --without-qt --disable-atomic-refcount
--without-qhull --without-hdf5 -without-glpk
--with-blas=-lblas --with-lapack=-llapack
--with-arpack-libdir=/usr/local/lib --with-qrupdate-libdir=/usr/local/lib
--with-amd-includedir=/usr/local/include/ --with-amd-libdir=/usr/local/lib
--with-camd-includedir=/usr/local/include/ --with-camd-libdir=/usr/local/lib
--with-colamd-includedir=/usr/local/include/ --with-colamd-libdir=/usr/local/lib
--with-ccolamd-includedir=/usr/local/include/ --with-ccolamd-libdir=/usr/local/lib
--with-cholmod-includedir=/usr/local/include/ --with-cholmod-libdir=/usr/local/lib
--with-umfpack-includedir=/usr/local/include/ --with-umfpack-libdir=/usr/local/lib
--with-fftw3-includedir=/usr/local/include/ --with-fftw3-libdir=/usr/local/lib
--with-fftw3f-includedir=/usr/local/include/ --with-fftw3f-libdir=/usr/local/lib*

export LD_LIBRARY_PATH=/usr/local/lib:/usr/local/lib64 is set in the shell environment. Various other packages were installed with *apt-get* including *libmpfr*, *libgmp*, *gnuplot* and *texlive*.

Monochrome printing

Monochrome printing of this document is supported by:

- hiding coloured hyperlinks in the *printed* PDF document by compiling this document with:

```
pdflatex '\newcommand\DesignOfIIRFiltersMono{} \input{DesignOfIIRFilters}'
```

The *DesignOfIIRFiltersMono* flag enables the following L^AT_EX code:

```
\usepackage[hidelinks]{hyperref}
```

- setting the Octave default line palette to all black in *src/test_common.m*:

```
if getenv("OCTAVE_ENABLE_MONOCHROME")
    set(0, "defaultaxescolororder", zeros(size(get(0, "defaultaxescolororder"))));
endif
```

The following command enables both these changes:

```
make cleanall && OCTAVE_ENABLE_MONOCHROME=1 make -j 6 monochrome
```

Aegis

I use the *aegis* software change management system written by Peter Miller [163, 122]. To build *aegis* with the patch provided in this project:

```
cd /usr/local/src/aegis
tar -xf aegis-4.24.tar.gz
cd aegis-4.24
patch -p1 < ../../aegis-4.24.patch
./configure CXXFLAGS="-fpermissive -std=c++98" CFLAGS="-std=c99"
make && make install
```

To build *fhist* [123] with the patch provided in this project:

```
cd /usr/local/src/fhist
tar -xf fhist-1.21.D001.tar.gz
cd fhist-1.21
patch -p1 < ../../fhist-1.21.D001.patch
./configure
make && make install
```

fhist requires the *libexplain*[124] library.

GitHub jekyll

A GitHub repository for this project is at <https://www.github.com/robertgj/DesignOfIIRFilters>. To test the *github-pages* documentation for the project, install a local version of *jekyll* as follows:

1. Install ruby:

```
dnf install ruby ruby-devel
```

2. Install RPM macros:

```
dnf install redhat-rpm-config
```

3. Set the installation location for GitHub jekyll:

```
echo '# Install Ruby Gems to ~/.gem' >> ~/.bashrc
echo 'export GEM_HOME=$HOME/.gem' >> ~/.bashrc
echo 'export PATH=$HOME/bin:$PATH' >> ~/.bashrc
source ~/.bashrc
```

4. Install GitHub jekyll:

```
wget https://github.com/jekyll/jekyll/archive/master.zip
unzip master.zip
pushd jekyll-master
gem install jekyll bundler
popd
```

5. Install GitHub jekyll-paginate:

```
wget https://github.com/jekyll/jekyll-paginate/archive/master.zip
unzip master.zip
pushd jekyll-paginate-master
gem install jekyll-paginate
popd
```
